the proportion of aged persons remained relatively high. In technically advanced countries reductions in mortality at late ages may be expected to increase the proportions of aged persons. (A systematic exposition of these principles is given by Ansley J. Coale, "The Effect of Changes in Fertility and Mortality on Age Composition," *The Milbank Memorial Fund Quarterly*, 34:79-114 [Jan. 1956].)

The age distributions of population in different countries (see Table V) are mainly due to differences in the levels and trends of fertility. They have also been influenced in varying ways by migrations, war losses and differences in mortality—though these effects are generally less important than the influence of variations in fertility. The migration of young adults, who bring children with them or soon have children in the area to which they move, is likely to swell the numbers both of adults in the middle ages and of children in the receiving country while the proportion of aged persons remain low—with reverse effects on the population of an area from which there is a large net out-movement.

The division by sex of a population, or of its component age classes, at any moment is determined quite simply, apart from the influence of migration, by the ratio of males to females at birth and the relative proportions of males and of females who have survived from birth to successive ages. See SEX.

MIGRATION

It is possible to distinguish three major kinds of spatial population movements: tribal wanderings and expansion by conquest into new lands—a process continued in the form of military occupation and colonization; forced transfers of people, including the acquisition of captives, the movement of slaves and the expulsion of minorities for political reasons; and the free movement of individuals. (The movement of indentured or contract labourers, which in some situations includes an element of force or fraud, is somewhat intermediate between the last two types.) Migration usually refers to the free movement of individuals; but other types of movement have been important forces in determining the present distribution of the world's population, and the 20th century has been plagued by forced movements on a large scale (see MINORITIES; REFUGEES).

The free movement of individuals is directed mainly toward the adjustment of people to economic opportunities—though it is influenced by diverse motives and has complex social and cultural aspects. Migration as a process of economic adjustment is often impeded by ignorance, attachment to habitual sites, the costs and risks of migration, and political barriers. Moreover, the sheer magnitude of population and the force of natural increase in the major regions of limited opportunity exclude the possibility that international migration can be a major factor in raising the levels of living of these regions. Migration seems to have been economically most effective when great resources held by small populations have been open to migrants, or there has been a great expansion of economic activities in which prospective migrants could be absorbed, and when migration has been associated with other transitional economic and demographic processes in the countries of origin.

The second of these relations is illustrated by the progressive shift southward and eastward of the areas of overseas emigration from Europe, with a spontaneous diminution of outflows from western and northern Europe as their industries expanded and their birth rates declined. It is also illustrated by the post-World War II movement of Puerto Ricans to the mainland of the United States, associated with the formation of new economic enterprises, progress in education and an initial trend toward modification of fertility.

Although migration varies greatly in magnitude and significance under different conditions, some approaches have been made to the formal analysis of internal migration (within nations) and the magnitudes of various streams of international migration at different times have been estimated. There is also much information about the characteristics of migrants and their adjustments, but this is not easily summarized. The total number of overseas migrants passing from Europe to the Americas, Oceania and Africa

from 1800 to the beginning of World War II is estimated as being in the vicinity of 60,000,000 persons, of whom about two-thirds to three-fourths remained abroad. These immigrants and their descendants have increased more rapidly than the people in the countries of origin so that their number now approaches that of the population of Europe outside the Soviet Union. There were also smaller but important movements from China, Japan and India to other continents, as well as within Asia.

The partition of India in 1947 involved the forced movement of some 17,000,000 persons. World War II uprooted 25,000,000 to 30,000,000 people in Europe, and there was a net overseas migration of more than 4,000,000 persons from Europe during the first postwar decade, 1946-1955. There were 600,000 displaced persons on the rolls of the International Relief organization in 1946. These were absorbed in new situations; but, because of unresolved political conflicts, the Arabs displaced by the formation of Israel in 1948 remained in refugee camps into the 1960s.

Postwar emigrants from Italy, Spain and Portugal went mainly to Latin America. Most of those from northern and western Europe, including Germany, went to the United States or to Canada, Australia, New Zealand, South Africa or Israel. Migrants from eastern Europe, mostly displaced persons, were widely dispersed; but they contributed a large contingent to the formation of the population of Israel.

See also MIGRATION.

THEORIES AND POLICIES

The movement and structure of a population involves the formation of new lives and their persistence through spans varying from a moment to a century. These demographic processes can be measured, and possible interrelations among them can be analyzed in abstraction; but they are essentially biological processes and in human societies they are largely controlled by economic, social and psychological conditions. Moreover, population movements in turn influence all other human affairs. They have social determinants and consequences. The objective study of population in its biological and social context, therefore, can aid in the formation of realistic public policies.

Turning to aspects of population theory that are related to social issues, mention still must be made of the century-old debate between the exponents of two conflicting dogmas, expounded by Thomas Malthus and by Karl Marx, about relations between population and economic conditions. Each of these dogmas contains sufficient truth to inspire enthusiasm in its disciples, but each is a gross oversimplification and distortion of actual situations.

Malthus, who in 1798 published the first edition of *An Essay on the Principle of Population as It Affects the Future Improvement of Society, with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and Other Writers*, held that the increase of population enforced by "the attraction between the sexes" constantly tends to exceed the resources for its sustenance and is always subject to the "positive checks" of famine, war and disease. Each advance in the arts is absorbed by a consequent increase of population, thus preventing any rise in the general level of living. This is, indeed a fair statement of the situation in much of the world prior to the time of his essay and in some areas at later times. But he proceeded on the fallacious assumption that increases in production could never exceed, or even equal, increases in population. He later modified this position by suggesting that under some conditions population might be brought into a more favourable balance with production through the "preventive check," by which he meant the postponement or avoidance of marriage and procreative activity. He repudiated M. Condorcet's suggestion that fertility might be controlled within marriage not only on moral grounds but also for economic reasons because he viewed poverty as a necessary stimulus to economic activity. Some later proponents of birth control who drew support from his economic doctrine called themselves Neo-Malthusians. Malthus applied his exposition of "the population principle" in opposing certain welfare measures which he viewed as futile and dangerous and, in general, repudiated the idea of improving the condition of mankind through

changes in economic and social institutions. Marx viewed revolutionary changes in economic and social institutions as inevitable and as leading toward an ideal society. He violently attacked Malthusian theory, just as Malthus had attacked the utopian socialism of Condorcet and Godwin. He equated overpopulation with actual, or latent, unemployment; he described relative overpopulation in this sense as essentially and purely a phenomenon of the capitalist system. Exponents of Marxist doctrine have generally viewed the control of population and changes in economic institutions as alternative and incompatible approaches to the advancement of levels of production and income.

Most contemporary demographers and economists view constructive changes in economic institutions, the advancement of education and the control of fertility as essentially complementary processes—none of which can be effective in the long run unless reinforced by the others. They point to specific ways in which rapid increase of population in low-income countries hampers economic and social development. This type of analysis was well summarized in the following quotation from a statement prepared by the United Nations Secretariat.

To sum up, population enters into the problem of achieving satisfactory standards of living in the under-developed countries in three principal ways. First, their high birth rates create a heavy load of dependent children per adult. This makes it difficult to save enough, over and above what is required for the support of the workers and their dependents, for needed investments in equipment for economic development. It also seriously complicates the problem of providing the children with the education that is essential for social and economic progress in the long run. This aspect of the population problem is common to all the under-developed countries. Second, falling death rates with high birth rates bring about a rapid increase of population. Large investments must be made to keep the growing numbers of workers equipped even with the same inadequate amounts of working equipment per man as they have had in the past. So the possibilities for investments which would improve the equipment and raise productivity per worker are diminished. This speeding up of population growth, aggravating the shortage of capital, is now taking place in very many under-developed countries, wherever successful public health campaigns have greatly reduced death rates. Third, many of the under-developed countries have an excessive density of agricultural population in relation to the area of cultivated land. The average farmer has too little land to make a satisfactory living for himself and his family. Not all under-developed countries face this difficulty, but it exists in some which have large amounts of unused land, as well as in those where nearly all the cultivable land is fully occupied. At least some of the countries now suffering from acute agricultural over-population might be able to employ all their numbers to good advantage, and benefit in the long run from a substantially larger population, if they were better equipped to utilize the land resources which they possess, or if they could industrialize. But neither the necessary improvements of agriculture nor the development of industry can easily be accomplished, and the difficulties are increased by high birth rates and rapid population growth. It appears that even in a country where population growth would be economically advantageous in the long run, economic progress will be hindered if the birth rate is so high and if the population grows so rapidly as to put an excessive strain on the economy. (From *Population Growth and the Standard of Living in Under-Developed Countries*, a summary of relevant chapters of UN Dept. of Social Affairs, *The Determinants and Consequences of Population Trends*, UN Population Studies no. 20 [1954].)

The social aspects of population have generally received much less attention than the economic aspects, though in some situations they may be even more important. For example, there are important relations between population trends and education. A high ratio of children to adults, characteristic of many poor areas with high fertility, requires a larger expenditure per adult to maintain a given standard of schooling than where the proportion of adults is higher, and may hamper the recruitment of qualified teachers. Again, the character of the adult population in areas of heavy immigration, e.g., most cities, is strongly affected by levels of education in other regions. This reinforces the thesis that education is not purely a matter of local concern. Moreover, if the less-educated elements in a population are more reproductive than those with higher education, the cultural force of education in successive decades is weakened. This trend may be largely a transitional phenomenon; but the extent to which it may reflect persistent conditions requires greater attention. On the other hand, the advancement of education may be a potent force in promoting the regulation of births. These brief comments suggest

larger and more complex problems on which as yet there is little knowledge. The distribution of genetic factors is inevitably affected by differences in reproduction rates. But, again, this is a momentous issue on which present knowledge is sadly deficient. Some governments, including among others those of Sweden, the Soviet Union, Japan and many of the state governments of the United States, have taken special measures (sterilization) to control fertility by persons handicapped by defects or diseases that frequently involve genetic factors.

During the late 1920s and the 1930s, when birth rates were falling rapidly in Europe, North America and Oceania, there was much alarm about "the retreat from parenthood"—reinforced in some countries by considerations of national security. Demographers were to some extent responsible for exaggerating the dangers in this situation through misplaced confidence at that time in the net reproduction ratio as an index of intrinsic population trends. Moreover, some economists viewed the slackening of population growth as tending to cause economic stagnation and chronic unemployment. It was, in any case, apparent that demographic changes were increasing the proportion of aged persons in the population.

These considerations led to the advocacy of measures for promoting the maintenance and growth of population as a matter of public policy. Quite different measures to this end were advanced in different countries and by different groups within the same country. In France concern about population trends, in conjunction with other interests, led eventually to a comprehensive system of family allowances and related measures, in which the government still makes a large investment each year, which actually offset at least in large part the costs of additional children in many French families. Some programs of financial aid to families with children have been adopted in most European and many non-European countries, including Canada. These programs are usually designed to serve various ends, and it is often difficult to say to what extent they express population policies. Moreover, most governments have been reluctant to authorize expenditures on a scale comparable to that accepted in France. More blatant but less expensive pronatalist measures were inaugurated by the Italian Fascist and the German National Socialist regimes.

Laws against the promotion or sale of contraceptives, as such, as well as stringent legislation against abortion are supported in some countries by demographic as well as religious considerations. The qualitative aspects of population trends were taken explicitly and seriously into account in general population policies only in Sweden. And even there the early program, which included this emphasis along with other welfare features, has been revised in favour of direct subsidies to families with children. Many governmental programs designed to promote fertility without much expenditure of public funds had practically no effect. In some other countries, notably in France, it is impossible to say to what extent pronatalist programs may have influenced actual population trends.

It is now generally recognized that the rapid increase of population in the less developed countries, at rates of 2 to 3½% per year, impedes their economic and social development. This principle is accepted by all responsible students of population though there are wide differences in emphasis and interpretation. Communist theoreticians who formerly denied or ignored this problem now tend merely to insist that changes in economic institutions are fundamental and that such changes will induce a spontaneous response toward controlled fertility. The Soviet Union and most of the Eastern European nations have legalized abortion and promote contraception, though in theory this is intended only for the welfare of the individual families rather than as a means of population control. Moreover, the Communist regime in China, according to a statement of Premier Chou En-lai (Feb. 1964), encourages delayed marriage and the control of births within marriage as a factor in achieving its economic objectives. Leading Roman Catholic theologians also recognize the serious economic and social consequences of the persistence of high fertility in association with declining mortality in nations with limited resources. They accept the regulation of fertility as a family goal, but insist

that the means of achieving this goal must conform to approved moral principles.

Many of the governments of the less developed countries, following the lead of India in its first five-year plan (1951-56), now promote planned parenthood as a national policy—either directly through public agencies or through public assistance to private agencies. Besides India and mainland China, the list includes Pakistan, Ceylon, Singapore, Malaysia, South Korea, Taiwan (Formosa), Turkey, Egypt, Tunisia, Morocco, Mauritius, Kenya, Honduras, Puerto Rico, and Chile. The General Assembly of the United Nations in 1962 adopted a resolution calling attention to the importance of population problems; a specific clause authorizing the provision of technical assistance in this field was deleted on the ground that it was unnecessary because the secretary-general has the authority to consider any requests for assistance by member governments. The UN Economic and Social Council in 1965 voted to increase "the amount of technical assistance in population fields available to governments of developing countries upon their request." The World Health Organization in 1965 also gave limited approval to this principle. The United States government, under Presidents J. F. Kennedy and L. B. Johnson, moved from official indifference to questions of population policy toward positive action in several ways in that country and the extension of technical assistance to other countries at their request.

The results of official programs, notably in India, were at first discouraging. The obstacles to changes in personal behaviour in a vast illiterate population dispersed in small villages are obviously enormous. Subsequent events have provided grounds for greater optimism. Methods of organization and communication have been improved on the basis of early experimentation. The appropriation for this work was increased in India from 1,500,000 rupees in the first five-year plan to 265,000,000 in the third plan and 950,000,000 in the fourth plan (1966-71). Equally intensive programs have been inaugurated in some other countries. Moreover there has been a large response in various low-income populations to new contraceptive techniques, notably intra-uterine devices and pills to regulate ovulation (see BIRTH CONTROL), that are more effective and more acceptable than those previously available. Therefore, it now appears that family planning programs may have an important influence on future population trends. If so, this success will not in itself assure great advances in the well-being of people who are now impoverished, but it will remove one of the major obstacles to such progress and facilitate more rapid and sustained economic and social development.

POPULIST PARTY, a short-lived minor political party that flourished in the United States in the 1890s. Officially named the People's Party of the United States of America, it was founded at Cincinnati, O., May 21, 1891, by a mass convention of delegates representing the discontented farmers of the Northwest and the South. Following another preliminary convention held at St. Louis, Mo., in February 1892, the Populists met in national convention at Omaha, Neb., on July 4, 1892, and nominated James B. Weaver of Iowa for president and James G. Field of Virginia for vice-president. The platform of the new party demanded principally the free and unlimited coinage of silver at the ratio of 16 to 1; the repossession by the government of unused lands it had given to the railroads; government ownership and operation of all railroad, telegraph and telephone facilities; and a graduated income tax. In the presidential election of 1892 the Populist ticket polled 22 electoral votes and more than 1,000,000 popular votes. By fusing with the Democrats in certain states the Populists were able also to elect several members of Congress, three governors, and hundreds of minor officials and legislators, nearly all in the Northwest. In the South most of the farmers refused to endanger

white supremacy by voting against the Democratic Party.

Populist gains in the midterm elections of 1894 were considerable, but when the Democrats nominated William Jennings Bryan in 1896 on a free silver platform, the Populists endorsed him, although nominating their own vice-presidential candidate, Thomas E. Watson of Georgia. After Bryan's defeat, most Populists became Democrats. A small residue known as "fusionists" endorsed Bryan, the Democratic candidate, again in 1900, while another element of the party nominated Wharton Barker of Philadelphia. A splinter group supported "middle-of-the-road" tickets, both state and national, as late as 1912.

POPULONIA, the Roman and modern Italian name for an ancient Etruscan town, *Pupluna* or *Fufluna*, named after the Etruscan wine-god equated with Bacchus, *Fufluns*. Situated on the western coast of central Italy on the Monte Massoncello peninsula at the modern Porto Baratti near Piombino, it was the only large Etruscan city directly on the sea. Two legends about the origin of Populonia were current in antiquity, both preserved by the commentator Servius (4th century A.D.): one, that it was a colony of Corsica, and another, that it was a colony of the Etruscan city of Volterra. Whatever truth there is in these traditions, the reason for the city's existence can be seen in the vast ironworking scoriae in the area of the city. These are the result of smelting ores from the nearby island of Elba, and it is clear that both silver and iron ores were imported from that island and perhaps also from Corsica. The earliest tombs lie below the level of the scoriae and are rich in cast metal, especially harness and chariot fittings. As a result of the metal trade the city rose to wealth and prominence and was the first city in Etruria to issue a silver coinage (second half of the 5th century B.C.). Many examples survive in the S. Cerbone and Porcareccia graveyards of both Villanovan pit tombs and chamber tombs of the Etruscan era (some in the false cupolas of Anatolian type). There is evidence from the tomb material of the presence of foreign traders, and Populonia is the only Etruscan city where Carthaginian pottery has been found. The city had two centres, an older centre on the hills of Molino and Del Castello and a later one near the port.

Early in republican times the city lost most of its prestige: it suffered greatly in the wars between Rome and the Boii in 282 B.C. and later in the civil wars between Marius and Sulla, whose troops besieged it in 80 B.C. After these wars the older part of the city was made a *municipium*.

Although the city was decadent and ruinous by the 4th century A.D., and its port ceased to function, Populonia continued until the 11th century to be the seat of a bishopric which later passed to Massa Marittima. Little is known of it in the Middle Ages except that it was made a dependency of Lucca under the Lombards and was still of some importance in the days of Charlemagne, who gave the city as a gift to Pope Hadrian I.

See A. Minto, *Populonia* (1943).

(Wm. C.)

PORBUNDER (PORBANDAR), a town and port on the Arabian Sea in Junagadh district of Gujarat, India, lies 275 mi. (443 km.) NW of Bombay. Pop. (1961) 75,081. The town is the seaboard terminal of the railway from central Gujarat, and has an airfield. It is a centre of silk, cotton, cement, salt, and chemical industries, and has a trade with the Malabar and Konkan coasts, East Africa and the Persian Gulf. Porbunder was the birthplace of Mahatma Gandhi (1869). The ancient town was known as Sudamapuri from Sudama, a devotee of Sri Krishna, and is mentioned in the Bhagavad Gita.

The former princely state of Porbunder merged with Saurashtra in 1948 and with Bombay State in 1956. On the division of Bombay State in May 1960, it became part of Gujarat.

PORCELAIN: see POTTERY AND PORCELAIN.

PORCELAIN ENAMELING. A porcelain enamel is a thin layer of glass fused to a metal to enhance its beauty, to prevent corrosion, or both. Porcelain-enameled iron is used extensively for both domestic and industrial articles. In addition to its use for kitchenware (see *Enamelware*, below), bathtubs and

sinks, it is used extensively for table tops, refrigerators, washing machine tubs and stoves. Industrially, it is used for advertising signs, chemical and food tanks of large sizes, hospital furniture, grocery, meat market, supermarket and restaurant equipment, and has found application in architecture for the facing of the outsides of buildings. A porcelain enamel, being a glass, has the properties of glass; namely, its hard, glossy surface and resistance to solution, corrosion and scratching. The metal backing and design greatly influence its strength and resistance to damage. The quality of porcelain enamels varies greatly, depending upon the glass used, the design and the manufacturing technique.

History.—Although the term porcelain enameling (also called vitreous enameling or enameling) did not come into common use until about 1929, enamels were used far back in the early history of man, first as glass beads fused onto metal, later as medallions and finally, in the first half of the 18th century, as a protective surface. Although jewelry enamels, art pieces and photographs in enamels are still made and highly prized (for cloisonné, champlevé, etc., see ENAMEL; JEWELRY), enamels on sheet steel and cast iron constitute the principal part of the modern industry.

Manufacture.—Although the early developments took many years, the transition of enameling from an art to an industry in the early part of the 19th century proceeded very rapidly. Cast-iron dry-process enamels were the first to be used on a large scale. In this process, the castings, such as bathtubs, were first sand-blasted to give them a clean surface. The grip or ground coat was then applied. This ground coat consisted of a powdered glass, clay and water suspension with a consistency about like that of cream. This was dipped, slushed or sprayed on the cool casting and allowed to dry. The ware was then introduced into a furnace at about 900° C. and allowed to come to the temperature of the furnace. The hot ware was withdrawn from the furnace and powdered glass dusted through a screen over it. This powdered glass melted as it fell on the hot ware and formed a continuous layer of enamel. Several applications were generally made, the ware being returned to the furnace for reheating before each application. This process is particularly applicable to the manufacture of heavy castings.

Another process which has come into common use is that of wet-process cast-iron enameling. This is used on lightweight or thin castings and has been adopted extensively in the stove industry. In this process, the ground coat is generally applied as a suspension of the glass with clay in water, dried and then fired in a furnace

prepares the surface for enameling. Sheet-steel enameling requires a ground coat containing a small percentage of cobalt to give it adherence. This ground coat is applied by the wet process, dried and then fired in a furnace at about 830° C. After the ware has been removed from the furnace and cooled, a second coat of cover enamel is applied by the wet process. This cover coat may be of any desired colour and may have special properties depending upon the use to which the ware is to be put. It is commonly sprayed or dipped onto the ware, allowed to dry and then fired at about 830° C. Additional coats of enamel are sometimes applied, and finally the decoration is applied and fired into the last coat.

Although enameling is an important industry in most countries, the use of automatic equipment, technical control and mass production is outstanding in the United States.

Enamelware.—Metal kitchenware, such as pots and pans, the surface of which is protected and decorated by a thin layer of porcelain enamel is known as enamelware. Prior to the advent of enamelware such utensils were made of pottery, copper, cast iron and to some extent tinned sheet iron. Aluminum and stainless steel, introduced in the 19th century, have come into common use.

In the kitchenware industry, enamelware is produced chiefly in large modern plants, with machine operations and a great deal of automation and control. Ware made in the second half of the 20th century is far superior to any of that made prior to World War II. In the manufacture of enamelware a good grade of low-carbon sheet iron is formed in the shape of the utensil by pressing or drawing, by spinning and by trimming; the handles, spouts and ears are welded in place by spot or resistance welding. The ware is then cleaned in a chemical detergent bath, rinsed in water, pickled in acid (usually 5% sulfuric acid), rinsed and neutralized in a bath of sodium hydroxide, borax or sodium cyanide. In some cases the ware is treated in a nickel sulfate bath prior to neutralizing to improve enamel adherence. The shapes are finally dried, sorted and inspected.

Enamel glasses are prepared by melting the raw materials together and quenching in a water spray and bath. These operations are called smelting and fritting, and the product, which is broken glass, is called frit. The frit is dried and weighed with mill additions such as water, clay and special suspending agents. This mill batch is charged into ball mills of about 1,000- to 3,000-lb. capacity and ground to a fineness of about 2% on a 200-mesh sieve. The product is a thick slurry called slip, the properties of which must be accurately controlled.

Enamel usually is applied in two coats each being fired separately. The first coat, called a ground coat, is an enamel containing cobalt. A typical composition is shown in the accompanying table. It usually is applied to the shapes by dipping, the properties of the slip being such that the excess drains off or is thrown off in the special handling of the ware just after it is removed from the slip bath. After drying it is fired, usually in a continuous conveyor furnace, at about 1,500° F., with four minutes in the hot zone of the furnace.

The ground-coated ware is next coated with the slip of the cover enamel (see table) in a similar manner, dried and fired. Where white is desired, the cover enamel is usually an acid-resistant titanium opacified enamel. Special compositions are needed for the colours, for the bead on the rim or for handles. In very special cases a third firing is used for special decorations.

Enamelware is usually acid-resistant, withstanding fruit and vegetable acids to a high degree. When made under modern conditions, it is very resistant to impact. The enamel fails only when the piece is subjected to a deformation of the iron, which results in a cracking of the glass coating. Enamelware is very resistant to thermal shock, but cold water should not be put in a hot dry pan. Enamelware will withstand all temperatures used in cooking. It has a hard, scratch-resistant surface and can be cleaned with all common cleaning materials, but harsh abrasives such as sand should not be used, as they scratch any glass surface.

at about 750° C. The ware is removed from the furnace, cooled, the second coat applied and then refired. This process is sometimes known as the U.S. process for enameling cast iron.

Sheet-steel enameling has become the process most widely used for porcelain enamels. In this process, the sheet steel is fabricated and put through a cleaning and pickling process which pre-

PORCH, originally a roofed structure, usually open at the sides, to protect the entrance of a building; loosely used of any projecting portico, or even of any colonnade and, in the United States, of any roofed structure open at the sides and front, attached to a house or other building; synonymous with veranda or piazza. A sleeping porch is such a structure usually opening from an upper story.

ALINARI
PORCH OF SAN ZENO MAGGIORE,
VERONA. 12TH-CENTURY ITALIAN
ROMANESQUE

Of the porch proper there are few extant remains prior to the classic period, although Egyptian wall paintings seem to indicate their occasional use with houses. The most important Greek porches are those of the Tower of the Winds at Athens (1st century B.C.), in which two columns of a simple Corinthian order carried a pediment. A similar porch exists in the so-called villa of Diomed at Pompeii. Houses in Rome sometimes had long colonnades facing the street which served as porches. During the Romanesque period simple projecting porches covering the western doors of churches are found instead of the earlier basilican colonnaded narthices. Especially interesting are the projecting

porches of the Italian Romanesque, such as that of S. Zeno Maggiore at Verona (12th century), in which the columns are carried on marble lions (as frequently in Lombard work) and at Modena (12th century) and Parma (13th century). In Apulia there are many similar porches of distinct Lombard character.

In France, especially in Burgundy, an even greater development of the porch occurred, in which it became a vaulted structure of great height and importance, two or more bays long and sometimes as wide as the entire church. The great porch of the abbey church at Vézelay (1132-40), sometimes termed an antechurch, is the largest and richest.

The English love of picturesqueness sometimes developed the porch to such an extent that it became almost a separate building which was called a "galilee," like that at Durham (1175). Galilees in mediæval churches are supposed to have been used sometimes as a court of law, or a place where corpses were placed before interment, but the galilee probably served chiefly as a chapel for penitents before their admission to the body of the church. Many fantastically rich projecting porches occur in French Flamboyant churches, such as that of the church of Notre Dame at Alençon (c. 1500), the pentagonal porch of St. Maclou at Rouen (c. 1520) and the side entrance of the cathedral at Albi (early 16th century).

The same richness of porch design is not found in English Gothic churches, where western doors are often small and unimportant. The other type of porch, the small projecting gabled feature projecting from the north or south walls of the nave, was, however, highly developed, throughout the course of English Gothic.

In the larger city churches there was frequently a room over the porch, sometimes known as a porch chamber and sometimes incorrectly termed a parvis. These seem to have been used sometimes as vestries, sometimes as treasuries and sometimes as chantry chapels. Similar porches, with chambers above, occur occasionally in Tudor mansions.

In Germany churches of the Flamboyant Gothic period are frequently decorated with western porches of the most fantastic richness, with a great use of cusping, pierced tracery and canopy work. Such are the double-arched entrance of the cathedral at Ulm (c. 1390) by Ulrich von Ensingen and the triangular porch

of the cathedral at Regensburg by M. Roritzer (1482-86).

During the Renaissance the porch was usually treated as a portico, but simple porches of two or four columns were exceedingly common features of the late 18th-century houses of England and the United States.

PORCUPINE, a name loosely applied to large, quill-bearing terrestrial rodents of the suborder Hystricomorpha. The New World porcupines belong to the family Erethizontidae, which consists of four genera: *Erethizon*, the North American porcupine found in wooded areas south of the tundra in Canada and the U.S. to northern Mexico; *Coendou*, the prehensile-tailed tree porcupines from southern Mexico to South America; *Echinoprocta*, the short-tailed porcupine found only in Colombia; and *Chaetomys*, the aberrant, thin-spined porcupine found only in Brazil.

The typical North American porcupine, *Erethizon dorsatum*, has a heavy, compact, arched body, about two feet long; the thick, muscular tail is an additional seven inches or so. The three-inch-long quills—hairs modified to form stiff, hollow spines—are interspersed among the dark, coarse, sparse guard hairs and brown-black underfur of the upperparts and the tail. The quills are black tipped and white based; they are erectile like the hairs.

Porcupines are slow moving, clumsy, methodical, and show little fear of other animals. They eat plant materials only and prefer the tender cambium layer directly beneath the bark, sometimes completely girdling a tree as they feed. Buds, tender twigs, and leaves are also eaten. Porcupines are solitary but not antisocial; several may be found in an especially suitable den site. Usually one young is born in the spring after about 209 days gestation.

Its spiny investiture has made the porcupine unpopular prey. It presents its rear to an enemy, and, if attacked, drives its powerful tail against the attacker. The quills are easily detached from the skin and remain with the barbed ends embedded in the assailant. The porcupine does not throw its quills at will, although they may become loose and be detached when the animal shakes itself. Because of their food habits porcupines are sometimes destructive of commercial timber. These prodigious gnawers also have a taste for other substances; many a woodsman has had his well-handled ax handle or canoe paddle destroyed by a "quill pig" who was after the salt and oil it contained. The flesh of the porcupine is tasty but fat; it is a godsend to persons lost in the woods.

The Old World porcupines belong to the family Hystricidae. They are also placed in four genera: *Hystrix*, the typical porcupine; *Thecurus*; and *Atherurus* and *Trichys*, the brush-tailed porcupines. *H. cristata*, the crested porcupine, is the largest terrestrial rodent of Europe; it ranges over southern Europe and the northern half of Africa. It has two types of quills, the longer ones measuring up to 1½ ft. long. Little hair is present in the quilled

JOE VAN WORMER—PHOTO RESEARCHERS

NORTH AMERICAN PORCUPINE (ERETHIZON DORSATUM)

areas of the skin. Crested porcupines are nervous, shy, and nocturnal. When disturbed they shake their bodies, thus rattling the hollow quills and producing a surprising amount of noise. Like their American counterparts, they display a wide variety of vocal sounds: grunts, squeaks, chattering, and whines. One or two young are produced following a gestation of 63 to 112 days.

A number of other species are widespread over Asia and adjacent islands and Africa, some species having only poorly developed quills. See ROBERT.

(K. R. KN.)

PORDENONE (GIOVANNI ANTONIO DE' SACHIS) (c. 1483-1539), a north Italian painter who, although basically influenced by Venetian painting, shows an element of violence which probably derives from Germany. He was born at Pordenone, in Friuli, in about 1483; however, the date of his birth rests only on the statement by G. Vasari that he died in 1540 (instead of 1539) at the age of 56. Pordenone was a pupil of Pellegrino da S. Daniele and other Friulian masters, but his style is founded on Venetian models and in particular on Titian; later he was influenced by Correggio and also by the Roman works of Michelangelo and Raphael and it is assumed, therefore, that he went to Rome, probably about 1515/16.

He worked in Treviso, Mantua, Genoa and Cremona as well as in Friuli and all over northern Italy. Even in Venice his work was so popular that for a short time he was a serious rival to Titian himself, and on one occasion the senate of Venice gave him the preference for a commission. Unfortunately, his frescoes in Venice have perished, but he painted a dome in Piacenza in the illusionistic manner of Correggio (1529-31). He was invited to Ferrara by Ercole II but died there soon after his arrival and was buried on Jan. 14, 1539. There are many documented and dated works by Pordenone, the earliest being a fresco at Valeriano, signed and dated 1506.

See C. Ridolfi, *Le Maraviglie dell' Arte*, etc. (1648; ed. by Hadeln, 1914-24); G. Fiocco, *Giovanni Antonio Pordenone*, 2nd ed. (1943).

(P. J. MY.)

PORDENONE, a town of Udine Province, Friuli-Venezia Giulia region, northeast Italy, lies on a small tributary of the Meduna, 31 mi. (50 km.) WSW of Udine by road, and in a plain about halfway between the Alps and the Adriatic coast. Pop. (1961) 37,204 (commune). Pordenone has many Romano-Gothic and Venetian palaces along its main street, and the 13th-century campanile of S. Marco is a national monument. There are fine modern buildings as well. Pordenone is on the railway from Treviso to Udine. Machinery, textiles, ceramics, and wood products are made. There are few Roman remains. The medieval river port (Portus Naonis) was a bulwark of the Trevigiani in their war against Aquileia. The latter destroyed it in 1233. It later became a fief of the Holy Roman Empire, passed to Venice in 1508 and became part of the kingdom of Italy in 1866. (Pr. P.)

PORGY, a name applied to various perchlike marine fishes of the family Sparidae, sometimes called sea breams. The body is oblong with the back more or less elevated; the jaws are armed with strong teeth, those in front being prominent and conical or incisorlike, those on the sides molarlike. Porgies are shore dwellers, occurring around the world, chiefly in warm seas. South Africa is especially rich in species, many of which are popular angling fishes. One temperate species, the northern porgy, commonly called scup (*Stenotomus chrysops*), ranges on the Atlantic coast from South Carolina to Maine. Scup grow to be about 18 in. long and 4 lb. in weight. They migrate northward and shoreward in spring, and southward and into deeper water in fall. They feed near the bottom on a variety of invertebrates and young fish. Scup spawn chiefly during the summer. The edible red porgy (*Pagrus pagrus*) of southern Europe and tropical America is believed to be the *Pagrus* referred to with much appreciation in ancient literature. (L. A. WD.)

PORIFERA, a phylum of the animal kingdom comprising the sponges. See SPONGE.

PORISMS, the title of a treatise written by Euclid (c. 300 B.C.), the author of the *Elements*. This book, no longer extant, is known only through the account given by Pappus of Alexandria (q.v.; c. A.D. 320) in the seventh of the eight books of his

Collection. Translated from the Greek into Latin toward the close of the 16th century, this work of Pappus was the subject of study by scholars who endeavoured to reconstruct the original, an effort not unconnected with the development of projective geometry.

The word porism (from *porizein*, "to carry" or "to produce") has several shades of meaning. In Euclid's *Elements* there are instances when a theorem (q.v.) is followed by the words "Porism." From this it is manifest that . . . and a statement that is a corollary to the theorem. For example:

Euclid III, 1. *To find the centre of a circle. Porism . . . if in a circle a straight line cuts a straight line into two equal parts and at right angles, the centre of the circle is on the cutting line.*

Euclid IV, 15. *In a given circle to inscribe an equiangular and equilateral hexagon. Porism . . . the side of the hexagon is equal to the radius.*

Euclid VII, 2. *Given two numbers not prime to one another, to find their greatest common measure. Porism . . . if a number measure two numbers, it will also measure their greatest common measure.*

Pappus, quoting "older writers," gave three classes of propositions:

A *theorem* is directed to *proving* what is proposed.

A *problem* is directed to *constructing* what is proposed.

A *porism* is directed to *producing* or *finding* what is proposed.

T. L. Heath suggests that the usual porism was "to prove that it is possible to find a point with such and such a property or a straight line on which lie all the points that satisfy given conditions." Tobias Dantzig summarizes the matter in these terms:

FROM B. L. VAN DER WAERDEN, "SCIENCE AWAKENING" (P. NOORDHOFF LTD.)

ILLUSTRATION OF THE FIRST OF EUCLID'S PORISMS. SOLID LINES INDICATE THOSE THAT ARE FIXED IN POSITION. BROKEN LINES SHOW TWO POSITIONS OF THE VARIABLE LINES

"The only thing certain about the *Book of Porisms* is the title, and even here there is no general agreement as to the sense in which Euclid used the term" (*Bequest of the Greeks*, p. 36, Charles Scribner's Sons, New York, 1955).

Pappus states that the *Porisms* contained 171 propositions and 38 lemmas. He gives examples of a few of the propositions and adds 38 lemmas of his own. He begins by stating a proposition that he says epitomizes the first ten of Euclid's porisms. It reads:

If in a system of four straight lines which cut one another two and two, three points on one straight line be given, while the rest except one lie on different straight lines given in position, the remaining point also will lie on a straight line given in position.

Thus in the accompanying diagram, three points of intersection of the lines *b*, *c*, *d* lie on *a*, namely *D*, *C*, *B*. Two other points *P* and *Q* are on the fixed lines *p* and *q*, with *p* and *q* intersecting *a* at *E* and *F*, respectively. In a second position the variable lines *b'*, *c'*, *d'* intersect the lines *p* and *q* at *P'* and *Q'*, respectively. It follows that the remaining point of intersection *R'* lies on the line that passes through the join of *p* and *q* and the point *R*. Pappus stated that this theorem is true of any number of straight lines intersecting two by two.

B. L. van der Waerden discusses the 13 lemmas that Pappus added to this porism, noting first that when two different positions of the variable lines are drawn, as is the case in the accompanying diagram, it is the theorem of Desargues (1636):

If two triangles are so situated that the lines joining pairs of corresponding vertices are concurrent, then the points of intersection of pairs of corresponding lines are collinear, or, as it appears in projective geometry, if two triangles are perspective from a point, they are perspective from a line, and conversely.

The lemmas that follow include the seeds of the ideas of the theorem of the complete quadrangle, of six points in involution, of four harmonic points and a special case of Pascal's hexagon.

Pappus' *Collection* was translated from the Greek into Latin by Federico Commandino (1509-75). Several editions of this work appeared, and in 1660 there was a revision of it by Carlo Manolesse. The Latin and Greek text with notes was published by F. Hultsch in 1876-78.

The problem of reconstructing the *Porisms* from the evidence offered by Pappus is a challenging one. H. W. Turnbull describes it as being like trying to follow a chess game by listening to the comments of an intelligent onlooker. Pierre de Fermat (1601?-65) was one of the first to attempt the reconstruction; Michel Chasles (1860) made a notable effort. In the course of this work Chasles was led to the important idea of anharmonic ratios. In his opinion, the *Porisms* belong to the modern theory of transversals and to projective geometry. H. G. Zeuthen (1886) suggested that the *Porisms* may have been corollaries to a fully developed projective geometry of conics. See also *GEOMETRY: Projective Geometry*.

PORK, the edible flesh of swine, is the most versatile and one of the most popular meats. Since ancient times it has been consumed by most of the omnivorous peoples of the earth with the notable exception of Orthodox Jews and Muslims (see *PIG*). Like other meats, pork is consumed as a cooked fresh meat, or it may be cured (or salted) to produce many types of products. In combination with other meats, or by itself, it is the principal ingredient in innumerable types of sausages (*q.v.*) and other meat foods. Pork and pork products are among the most nutritious foods; their caloric value is high and they are a good source of B vitamins and minerals.

Pork is usually derived from young animals which are slaughtered before reaching puberty. In this respect it differs from beef or horsemeat and is perhaps more comparable to lamb and veal than other meats. Carcasses of mature swine, such as cull sows, are generally used in sausage trimmings.

Swine produce more edible meat per pound of feed consumed than any other of the mammalian livestock species generally used

TABLE I.—United States Standards for Pork: Average Back Fat Thickness by Grade (in inches)

Carcass weight or carcass length	U.S. No. 1	U.S. No. 2	U.S. No. 3	Medium	Cull
Under 120 lb. or under 27 in.	1.2-1.5	1.5-1.8	1.8 or more	0.9-1.2	less than 0.9
120-164 lb. or 27-29.9 in.	1.3-1.6	1.6-1.9	1.9 or more	1.0-1.3	less than 1.0
165-209 lb. or 30-32.9 in.	1.4-1.7	1.7-2.0	2.0 or more	1.1-1.4	less than 1.1
210 lb. or over, or 33 in. or longer	1.5-1.8	1.8-2.1	2.1 or more	1.2-1.5	less than 1.2

as food. (Rabbits have an even higher feed efficiency but are not so generally consumed.) This high feed efficiency is the economic basis for pork's place as the meat of the common man, and also explains why it has been said that the average hog provides enough meat for two people and enough lard (*q.v.*) for three. Animal husbandrymen throughout the world are working successfully toward the general adoption of swine which produce carcasses with a larger percentage of lean meat and a smaller percentage of fat.

To facilitate marketing and give some indication of potential quality, pork carcasses are usually separated into grades according to length of carcass, back fat thickness, or some other measurement which is considered to be closely correlated with the amount of edible meat. The United States and Canada both use a combination of length and back fat thickness while Denmark, Britain, and countries which primarily produce Wiltshire bacon (see below)

TABLE II.—Danish Bacon Grading (October 1964)

Measurement	Danish AA	Danish A	Danish B
	Maximum		
Back fat thickness—on the point of the neck where the back fat is thickest	4.0 cm.	4.7 cm.	5.2 cm.
Back fat thickness—on the central point of the middle and extending 7 cm. on both sides of the point which is halfway between the other two measurements	2.0 cm.	2.9 cm.	3.4 cm.
Back fat thickness—on the top of the muscle which arches out above the loin into the back fat	2.0 cm.	2.7 cm.	3.2 cm.
Slight of lean measurement—taken 8 to 9 cm. from the edge of the back fat in line with the last rib	2.9 cm.	2.9 cm.	3.5 cm.

also include a "slight of lean" measurement or a measure for loin muscle area in their grading. Grading standards in the United States and Denmark in the 1960s are shown in Tables I and II.

A U.S. No. 1 hog carcass is one which is considered to have an ideal amount of fat for its weight or length. A No. 2 or No. 3 carcass is somewhat more fat than desirable, while medium or cull carcasses have too little fat to satisfy the demands of the trade for a firm carcass that will handle properly on the block when cut. Some authorities think that less fat would be acceptable in the No. 1 carcass; others feel that the present standards result in roast pork that is somewhat too dry because it lacks enough fat for succulence. The tables presented here are examples of grading systems rather than an indication of any exact values. The values upon which a system is based—including, for example, consumer preference—vary from country to country and from time to time; and any system represents a compromise of all the factors involved.

In the U.S. individual pork cuts, unlike beef or lamb, are not graded. In Canada and the United States pork carcasses are divided into separate cuts as shown in the figure. In European countries a similar system is used, except for Wiltshire sides. The latter consists of the whole side of pork with the head and feet removed. The Wiltshire side is used for Wiltshire bacon and is an important item of export in Denmark, Poland, Ireland, Holland, Sweden, and to some extent in other continental countries.

Except for the making of Wiltshire bacon, the hams, shoulders, and bacon are generally cured while the loins are eaten as fresh pork. A notable exception is so-called Canadian bacon, which consists of the cured loin muscle.

Curing and Cured Pork

Most pork consumed in Great Britain is cured as Wiltshire bacon; in the rest of the world somewhat more than half the pork produced is cured. In the United States and Canada the ham, shoulder, shoulder butt, bacon (belly), and some of the loin is generally cured. Curing takes many forms. Originally it was developed as a means of preserving meat for consumption weeks or months after slaughtering and dressing. It is a very ancient

art; salting of meat is mentioned by Homer, and it was probably common before that. With the development of rapid distribution and the wide use of refrigeration, the preservative action of heavy curing is not so necessary, and the process has gradually changed.

The two traditional curing procedures are called dry curing and brine curing, depending on whether the curing ingredients are applied in a dry state or in solution. The curing ingredients are sodium chloride (common salt), sugar, and either sodium or potassium nitrate (NaNO_3 or KNO_3). A typical mixture consists of about 8 lb. of salt, about 2 lb. of sugar, and about 2 oz. of NaNO_3 per 100 lb. of meat. For dry cures the salt mixture is rubbed over the surface of the pork, and for brine cures the ingredients are dissolved in a suitable amount of water. Salt is absorbed rapidly by the meat and affects the flavour and chemical characteristics of the muscle proteins. It also acts as a bacteriostatic agent, retarding spoilage. Sugar has an effect on flavour which is said to reduce the harshness of the salt, although excellent cured meats may be made without its use. The nitrate is reduced to nitrite by microorganisms and, to a lesser extent, by other substances in pork tissue, and combines with the myoglobin (the red pigment of muscle) to form the relatively insoluble pink or red pigments of cured meats. This fixed colour, which is one of the important attributes of modern cured meats, is called nitrosohemochromogen. After a suitable time of exposure to the curing substances, the meat is washed briefly with a shower of water, allowed to dry, and then heated in a smokehouse. The time in smoke varies widely for different products. The essential results are the hardening of the exterior surfaces of the meat due to heat coagulation of the protein, the drying effect of the warm atmosphere, a further fixation of the pigment probably due to heat denaturation of the protein portion of the pigmented substance, and finally, the deposition of chemicals from the smoke on the meat. These smoke chemicals (aldehydes, phenols, polycyclic compounds, and others) have both an antioxidant effect, which protects the meat from becoming rancid, and some bacteriostatic action which helps further to retard spoilage.

In the early 1900s it occurred to scientists that the curing process could be accelerated and made more certain if some nitrite, such as sodium nitrite (NaNO_2) were added to the cure. This would promote rapid colour fixation without waiting for bacterial reduction of nitrate. This has become general practice and most countries now permit the use of nitrite in cures.

A further and more dramatic speedup of the curing process occurred in the early 1930s with the development of artery pumping. It consists of introducing the curing brine into the arterial system of a ham or other pork cut. In the case of hams, brine equal to about 10% of the weight of the ham is forced, at rather high pressure, into the femoral artery with a large hypodermic needle and a pump. Following pumping, the cuts may be subjected to further curing by submerging in cover pickle or by rubbing with a salt mixture.

The modern so-called ready to eat or fully cooked ham of the American market is often cured by brine pumping followed by immediate smoking. The temperature of the ham is raised to about 155° F in the smokehouse. The whole procedure from fresh ham to cured and cooked product, ready for the market, may take as little as ten hours. This sort of product may be contrasted with a Smithfield-type ham which is cured by a dry salt mixture and a very long cool smoke. Such hams may remain in cure for about 3 days per pound of weight (thus a 15-lb. ham would be cured for 45 days), and in the smokehouse for another 25 to 30 days of intermittent smoking. Long cured or regular hams are cured for about 14 to 30 days in brine and smoked to an internal temperature of 140° F. Table III shows some of the chemical and nutritional properties of the lean meat of several types of ham.

The figures in Table III are averages of several samples but should not be regarded as more than a comparison between types. Curing methods differ so widely and change so frequently and there is such great variation among pork carcasses that the figures cannot be considered specifically accurate for any ham other than the ones analyzed. It is important, however, to note the high free-fatty-acid content, high salt content, and low moisture content of

TABLE III.—Composition of Lean Meat of Several Ham Types

Type	Moisture (%)	Protein (%)	Fat (%)	NaCl (%)	Free fatty acid (%)	Thiamin*	Riboflavin*	Niacin*
Canned	65.0	18.3	12.3	3.5		29.0	14.0	250
Ready to eat	68.6	20.8	6.4	3.6	.41	29.5	8.3	168
Long cured	67.1	21.3	5.9	5.2	.64	29.7	8.6	173
Smithfield	51.0	27.7	11.2	8.4	9.3	26.2	10.4	248

*Values given in micrograms per gram of protein.

the aged Smithfield ham as compared to the other three. The Smithfield ham owes much of its distinctive flavour to its high free-fatty-acid content.

Bacon.—In Canada and the United States the term bacon means the cured belly or abdominal wall of the hog. The flat abdominal musculature gives the alternate streaks of lean and fat in the bacon slice. Bacon may be cured in many ways, but in most modern plants it is given a quick cure with a machine which injects the bacon with curing brine through a large number of needles arranged in gridlike pattern. After a period in brine cure of from a few hours to several days, depending on the practices of the particular plant, the bacon sides are washed and given a light smoke. The usual American practice is to market bacon as packaged slices. Bacon slabs have all but disappeared from the general market.

Wiltshire Bacon.—In Europe, the entire Wiltshire side and the cuts obtained from it are referred to as bacon. In manufacturing this product, the pork sides (after chilling and removal of the head, feet, etc.) are pumped with the brine and then piled in vats holding from a dozen to several hundred sides. When a vat is filled, usually with one day's kill, brine is pumped into the vat from another which is ready to be emptied. Brine for Wiltshire bacon is not made up fresh for each batch of meat, as it is in American practice, but is reused as long as possible. Salt and nitrate and nitrite are added to the brine from time to time to bring it up to strength (about 23–24% NaCl) and the brine is brought back to volume. Wiltshire bacon is cured in brine for a period of seven to ten days, and then the sides are piled in another part of the curing cellar for "maturation." It is claimed that this process, which may take from three days to two weeks at a controlled temperature, distributes the salt more evenly and produces better colour and flavour. Following maturation, the sides may be sold smoked, or "green," i.e., unsmoked. The hind leg portions from Wiltshire sides are termed gammons and are frequently sold separately. The shoulders ("fore ends") are also often sold as separate cuts, but the rest of the side is normally sliced for sale.

A modern innovation, called "slice curing," consists of a process for slicing the raw "middles" (the sides minus hams and shoulders) and passing the slices on a conveyor through a brine tank. The resultant slices, which are cured in little more than an hour, are vacuum-packed in a plastic film for sale. This product is said to have better colour than, and to be as acceptable to consumers as, the traditional product that may take as much as three or four weeks to produce.

Public Health Aspects.—Swine may suffer from the parasitic disease trichinosis and pork may harbour the cysts of the parasite, *Trichinella spiralis*. To guard against the infection of humans, the meat inspection laws of the various countries contain provisions to prevent the consumption of infectious pork. In the United States and Canada, all pork products which are likely to be eaten without further cooking (such as ham) must be either heated to 140° F, or frozen, or salted in a specified manner which will kill the parasite. The trichina larvae are killed by heating to 137° F, and the common stricture to cook pork well done allows for more than an ample safety factor. In many European countries where the number of hogs handled by a plant is not nearly so large as in the United States and Canada, an actual microscopic inspection for trichina is conducted on each hog carcass. In these countries many pork products are prepared which are not cooked and such laborious inspection is necessary.

Like other meat products, pork products may become contaminated by food poisoning bacteria—especially during slicing or

handling under adverse conditions. Pork products, particularly cooked products, should therefore be handled under hygienic conditions and kept under refrigeration.

Merrill, "Composition of Foods," U.S. Department of Agriculture *Agriculture Handbook No. 8* (1963); N. E. Gibbons, *Wiltshire Bacon* (1953). (W. L. St.)

POROS (anc. Greek CALAURIA), an island off the east coast of the Peloponnese, Greece (area 9 sq.mi. [23 sq.km.]; pop. [1961] 4,422), included in the *nomos* (department) of Attica. It is separated at its western end by a narrow channel (*poros*) from the mainland at Troezen and consists of a mass of limestone joined by a sandy isthmus to a smaller mass of trachyte on the south, where the modern harbour town Poros stands.

Calauria was famous for its temple of Poseidon, the centre at an early date of an amphictyony (*q.v.*) of maritime states—Hermione, Epidaurus, Aegina, Athens, Prasiae, Nauplia, and Orchomenus in Boeotia; later Argos replaced Nauplia and Sparta took the place of Prasiae. Demosthenes took sanctuary there and poisoned himself to avoid arrest (322 B.C.). The Doric temple lay on a ridge inland, commanding a view of Athens and the Saronic Gulf; it was excavated in 1894 by the Swedes S. Wide and L. Kjellberg. Traces of porticoes and other buildings were also found.

English, French, and Russian plenipotentiaries met at Poros in 1828 to discuss the future of the new Greek state, and in 1831 the Greek admiral Andreas Vokos Miaoulis (*q.v.*) attempted to hold the town against Kapodistrias and blew up the "Hellas" in Poros Harbour.

PORPHYRIA, a group of genetic metabolic abnormalities characterized by the excessive formation and excretion of porphyrins or their precursors. Porphyrins are red pigments, of which protoporphyrin is the most widely represented in nature; it imparts the red colour to the circulating hemoglobin.

Two main forms of porphyria are recognized: porphyria erythropoietica (bone marrow) and porphyria hepatica (liver). The former is characterized by greatly excessive porphyrin formation in certain of the developing red blood cells. The urine is dark red and bones and teeth are reddish brown, due to the presence of uroporphyrin, which normally occurs only in trace amounts in the body and excreta. The accumulation of uroporphyrin in the skin is responsible for light sensitivity appearing in early infancy, with blisters and eventual scarring and deformity of face and hands. Enlargement of the spleen and anemia are common. Removal of the spleen is of benefit in some cases. Protection from sunlight is essential.

The hepatic group comprises (1) an intermittent acute form represented by formation of colourless precursors in the liver, attacks of abdominal pain, nervousness, weakness, or paralysis, at times fatal; (2) a late cutaneous form (commonly fourth to eighth decades of life, at times earlier) with marked porphyrin formation in the liver, photosensitivity, and scarring; and (3) cases combining features of (1) and (2). (C. J. Wa.)

PORPHYRY (234–c. 305), Neoplatonist philosopher and scholar who is important as both editor and biographer of Plotinus (*q.v.*) and because of the influence of his logical works on medieval thought, was born at Tyre (or Batanaea in Palestine). He originally bore the Syrian name Malchus ("king"), hellenized by Longinus into *Porphyrios* ("purple") in allusion to the colour of the imperial robes. He studied under the great scholar Cassius Longinus (*q.v.*) at Athens. In the year 262/263 he went to Rome and attached himself to Plotinus, the founder of Neoplatonism, with whom he remained for five years. These years were the decisive period in his life. Owing to severe overstrain which led him to contemplate suicide (very sympathetically and sensibly dealt with by Plotinus) he had to leave his master and retire to Sicily. But Plotinus had made him his literary executor, and 33 years later, in 301, at the age of 68, he produced what is incomparably his most important piece of work, an edition of the writings of Plotinus, the *Enneads*, to which he prefixed a biography of his master which is a noble testimony to the continuing devotion which the latter inspired in his pupil and is unique among ancient

lives of philosophers for its informativeness and reliability. Apart from this publication little is known of the later life of Porphyry. He returned to Rome some time after the death of Plotinus (though he probably did not engage in any organized philosophical teaching there; the school of Plotinus had come to an end with the last illness of the master). Late in life he married a philosophically inclined widow called Marcella.

Porphyry was a voluminous writer, not original but well-read and careful to give the names of his authorities. He has thus preserved in some of his works (notably the *De abstinentia*) important fragments of earlier philosophy. His extant works, besides the biography of Plotinus already referred to, are:

1. Philosophical and religious: *Aphormai pros ta noeta* (*Sententiae ad intelligibilia ducentes*), a collection of philosophical aphorisms borrowed or adapted from Plotinus; *Peri apoches empsychon* (*De abstinentia*), on vegetarianism; *Pros Marcellian* (*Ad Marcellam*), a work of edification addressed to his wife; the *Pros Anebo epistole*, an extremely skeptical "open letter" to Anebo on theurgy; the *Pythagorou bios* ("Life of Pythagoras"), probably part of a larger history of philosophy, written in Porphyry's youth; the introduction to and commentary on Aristotle's *Categories*, which played an important part in the development of medieval logic; the introduction (*Isagoge*) in a Latin translation by the Christian philosopher Boethius became a standard medieval textbook. Porphyry's great work *Kata Christianon* ("Against the Christians") was condemned to be burned in 448 and only fragments survive, from which it is clear that it was a scholarly and intelligent attack on Christianity. Fragments survive also of a work *Peri agalmaton* ("On Images") and of the *Peri tes ex logion philosophias* ("Philosophy from Oracles"), which may be identical with the work referred to frequently by St. Augustine as *De regressu animae* ("On the Return of the Soul"). Some fragments of the *Symmikta zetemata* ("Various Investigations") also survive.

2. Philological: *Homerika zetemata* (*Quaestiones Homericae*); *Peri tou en Odysseia ton nymphon antrou* (*De antro nympharum*), an example of the allegorical interpretation of Homer.

3. Scientific: a commentary on Ptolemy's *Harmonica* (incomplete); an introduction (*Isagoge*) to Ptolemy's *Tetrabiblos* (or *Apotelesmatica*); *Pros Gauron*, a work on embryology, dedicated to Gaurus, formerly attributed to the physician Galen, but now generally agreed to be by Porphyry.

BIBLIOGRAPHY.—There is no complete edition of the works of Porphyry. Biography of Plotinus in all editions of the *Enneads* of Plotinus (*q.v.*); text with German translation and commentary by R. Harder, *Plotinus Schriften*, vol. Vc, 2nd ed. (1958); *Sententiae* ed. by B. Mommert (1907); *Opuscula selecta*, containing *Vita Pythagorae*, *De antro nympharum*, *De abstinentia*, *Ad Marcellam* ed. by A. Nauck, 2nd ed. (1886); works on Aristotle's logic ed. by A. Busse, *Commentaria in Aristotelem graeca*, vol. 4, part 1 (1887); letter to Anebo in G. Parthey's edition of Iamblichus' *De mysteriis* (1857); fragments of work against Christians ed. by A. von Harnack in *Abhandlungen der Königlich Preussischen Akademie der Wissenschaften phil.-hist. Klasse* (1916) and in *Sitzungsberichte der Preussischen Akademie der Wissenschaften* (1921); fragments of the "Philosophy from Oracles" ed. by G. Wolff (1856) and see also J. J. O'Meara, *Porphyry's Philosophy from Oracles in Augustine* (1959); fragments of *Symmikta Zetemata* ed. by H. Dörrie (1959); *Homerika Zetemata* ed. by H. Schrader (1880–90); commentary on Ptolemy's *Harmonica* ed. by I. Düring (1932); introduction to Ptolemy's *Tetrabiblos* ed. by H. Wolf (1959) and cf. *Catalogus codicum astrologorum Graecorum*, vol. 5, part 4, pp. 190–228 (1940); *Pros Gauron* ed. by K. Kalbfleisch in *Anhang zu den Abhandlungen der königlichen Akademie zu Wissenschaften zu Berlin* (1895) and French trans. by A. J. Festugière, *La Révélation d'Hermès Trismégiste*, vol. 3 (1953).

PORPHYRY, a beautiful red or purplish rock used by the ancients for ornamental purposes when cut and polished. The name porphyry (Greek *porphyreos*, "purple") was derived from the older name porphyrites, which in the time of Pliny was applied to purplish and reddish rocks mottled with light spots. Although most of this material was of igneous (volcanic or shallow intrusive) origin, the early Italian sculptors erroneously considered it a variety of marble, of metamorphosed sedimentary origin. The famous red porphyry (*porfido rosso antico*) came from Egypt

where it was used in sculpture. Its beauty and decorative value were recognized by the Romans in the time of the emperor Claudius. For a long time the knowledge of its source was lost, but the original locality of the ancient quarries was rediscovered on the west coast of the Red Sea, where it forms a dike 80 or 90 ft. thick.

In a dark-red groundmass, porphyry contains many small white or rose-red plagioclase feldspars, black shining prisms of hornblende, and small plates of iron oxide. The red of the feldspars and of the groundmass arises from the partial conversion of the plagioclase feldspar into thulite (see ZOISITE) and manganese epidote (*q.v.*). These minerals also occur in thin veins crossing the rock. Many specimens show effects of crushing, which in extreme cases has produced brecciation.

Applications of Term.—In petrography the term porphyry is used to designate an igneous rock characterized by abundant relatively large crystals (phenocrysts) set in a matrix or groundmass of fine-grained to amorphous (apparently without crystal structure) material. The porphyries belong to a larger group of rocks, all of which possess a porphyritic texture (phenocrysts and groundmass). Thus, all porphyries have a porphyritic texture, but by no means are all porphyritic rocks true porphyries. Most generally perhaps, the term porphyry is restricted to those porphyritic rocks in which the phenocrysts abound or predominate and which consolidated at shallow depths beneath the earth's surface (hypabyssal rocks). Hence, the true porphyries are most commonly found in sills, dikes, and other minor intrusive bodies. Not uncommonly, however, the term is also applied to certain highly porphyritic volcanic rocks, which may resemble the intrusive porphyries.

In the United States the term porphyry is used chiefly in a textural sense. A simple and rather precise scheme is to modify the term by prefixing the common rock name which the porphyry most closely resembles chemically or mineralogically. Thus, granite porphyry, diorite porphyry, etc., are porphyries, compositionally equivalent to the plutonic (coarse-grained) rocks, granite, diorite, etc., respectively. Rhyolite porphyry and andesite porphyry, for example, correspond in composition respectively to the volcanic rocks rhyolite and andesite.

A distinction is to be made, however, between such terms as porphyritic granite and granite porphyry. The former is a true granite; that is, its texture is phaneritic (constituent grains visible without magnification). The latter is not a granite, because its groundmass is aphanitic (constituent grains indiscernible without magnification). A similar distinction is to be made between such terms as porphyritic rhyolite and rhyolite porphyry. Generally the porphyritic rhyolite has a higher proportion of groundmass, which is in itself finer grained or richer in glassy constituents, than the rhyolite porphyry.

The early petrographers (particularly in Europe), in their studies of porphyries and related hypabyssal rocks, placed great emphasis upon the mineral composition of the large crystals, the geologic age of the rocks, and the degree to which the rock had been altered. As a result a very complex and confusing nomenclature evolved. Some petrographers prefer to restrict the term porphyry to those types in which the large crystals are principally feldspar (with or without quartz) and to place those types with abundant, large crystals of olivine, pyroxene, amphibole, and mica under the lamprophyres.

It is the general practice outside the United States to subdivide the highly porphyritic rocks with an aphanitic groundmass into two classes. Those in which potash feldspar is dominant are called the true porphyries, whereas the plagioclase feldspar types are called porphyrites. The porphyries, under this scheme, are essentially equivalent compositionally to the granites, syenites, and nephelite syenites, whereas the porphyrites are compositional equivalents of the diorites and gabbros. In the United States the term porphyrite is nearly obsolete.

Origin.—Theories of origin of porphyries are manifold, and it is highly probable that different porphyries have formed in equally different ways. Many porphyries may have had an interruption in their course of crystallization. The phenocrysts may have

formed largely at depth (intratelluric crystals), where cooling of the magma (molten rock material) proceeded slowly, permitting the growth of large scattered crystals. Before complete congelation, however, the magma, with its suspended crystals, was erupted to higher levels and injected as dikes and sills into colder rocks. The cooling effect upon these thin injected sheets was so marked that the liquid phase was rapidly transformed to a fine-grained or aphanitic groundmass.

In other porphyries the large crystals may have developed mainly subsequent to injection. Certain minerals may have developed well-formed crystals before the viscosity of the melt increased sufficiently to retard and restrict diffusion. Changes in pressure on the magma and the loss of dissolved volatiles may have contributed to the formation of porphyritic textures. The role of certain trace elements in controlling crystal growth rates is of possible importance and needs further investigation. Inoculation and incorporation of foreign crystals may explain the porphyritic character of some rocks. (For processes of crystallization see GEOCHEMISTRY: *Geochemistry of the Lithosphere.*)

Occurrences.—Porphyries occur abundantly as dikes and sills, satellitic to larger masses of compositionally equivalent plutonic rock. Thus, granite porphyry and quartz porphyry are exceedingly common in regions where granitic intrusive rocks occur. Nephelinite- and leucite-rich porphyries, though rare, are associated with larger intrusions of nephelite syenite and leucite syenite. Diorite porphyries (porphyrites) accompany plutonic masses of diorite. Coextensive masses of porphyry may extend as veinlike projections and offshoots from larger parent masses of plutonic rock. Some porphyries, furthermore, appear as marginal phases of the larger intrusions. In such cases the plutonic masses and associated porphyries were probably derived from a common magma.

See A. Johannsen, *A Descriptive Petrography of the Igneous Rocks*, vol. iii (1937). (C. A. CN.)

PORPOISE, the common name often applied to any of the smaller, round muzzled toothed whales, but properly restricted to the genus *Phocaena*. Porpoises, along with dolphins and whales, are included in the mammalian order Cetacea. There is no sharp scientific distinction between porpoises and dolphins, but, generally speaking, the porpoise is smaller and does not have the characteristic beak nose of the dolphin. In North America "porpoise" is generally used to indicate the bottle-nosed dolphin (see DOLPHIN).

Like most other mammals, these superficially fishlike forms breathe air directly and bear live young which they suckle. The adult porpoises mate in late summer, and the female bears a single calf, almost a yard long, in about a year. Their life expectancy has been estimated at 30 years. Porpoises feed on schooling fish, such as herring and mackerel, as well as on squid and other marine animals.

The wide mouth is bounded by stiff, immobile lips, and the underjaw projects slightly. The teeth number between 80 and 100. In colour, the porpoise is black or dark gray above and white below, with black flippers. A single dorsal fin is triangular in shape and low.

The common, or harbour, porpoise (*Phocaena phocaena*) attains a length of 4-6 ft. It prefers coastal waters to the open sea and inhabits the North Atlantic area, entering the Baltic in summer; it is rare in the Mediterranean. A distinct form of the common porpoise appears in the Black Sea; one or two other species are found in the South Atlantic. The Pacific porpoise is a distinct species. The black finless porpoise (*Neophocaena phocaenoides*) inhabits the warm coastal waters of the Indian Ocean.

Porpoise has been used for food—the flesh resembles pork but has an odour somewhat disagreeable to most persons. The oil obtained from the soft fat of the head and jaw of the common porpoise has been used as a lubricant in the manufacture of watches, clocks, and other delicate mechanisms made of hard steel. The value of the oil lies chiefly in the fact that it is free from a tendency either to gum or thicken by oxidation, or to corrode metal, and in its ability to withstand exposure to very low temperatures without freezing or thickening to any great extent. The oil was also formerly used in lamps. See also WHALE. (K. P. S.; X.)

PORPORA, NICOLA ANTONIO (1686–1768), Italian opera composer and singing teacher, was born at Naples on Aug. 17, 1686. His first three operas were produced at Naples; others followed in Rome, Vienna, and Venice. He taught in Naples and Venice; among his pupils were the celebrated *castrati* Antonio Uberti (known as "Porporino"), Farinelli, and Caffarelli, and the poet and librettist Pietro Metastasio. After visiting Vienna in 1725 Porpora settled for a while in Venice where he taught at the Ospedale degli Incurabili, a famous music school for girls. In 1733 he went to London as a rival to Handel and as chief composer of the "Opera of the Nobility" at the theatre in Lincoln's Inn Fields and at the King's Theatre in the Haymarket. While in London he wrote five operas, among them *Polifemo*, *Davide e Bersabea*, and *Ifigenia in Aulide*, with parts for his remarkable pupil Farinelli. He had also secured the services of Handel's singers Francesco Senesino and Francesca Cuzzoni. But in 1736 Handel won the favour of Frederick, Prince of Wales, the chief supporter of the "Opera of the Nobility," and shortly afterward Porpora left England. In 1737 he was teaching at Venice and two years later at Naples, where he also produced two comic operas. In 1747 he taught singing at Dresden and the following year was appointed *Kapellmeister* there. Later he was at Vienna where he gave composition lessons to the young Haydn, who was greatly indebted to him. In 1758 he was in Naples. A revision of his opera *Il Trionfo di Camilla*, first produced at Naples in 1740, was given there in 1760 but it was not a success. Porpora's last years were spent in poverty. He died at Naples on March 3, 1768.

See F. Walker, "A Chronology of the Life and Works of Nicola Porpora," *Italian Studies*, vol. vi (1951). (Cs. Ch.)

PORRÉE, GILBERT DE LA: see GILBERT DE LA PORRÉE.

PORRES, SAINT MARTÍN DE (1579–1639), the Peruvian national patron of social justice, was born in Lima, the illegitimate son of a noble Spaniard, Don Juan de Porres, and a Negro woman, Ana Velázquez. As a youth, he was taken by his father to Ecuador and placed in school there. When official duties transferred the father to Panama, the boy returned to the care of his mother in Lima, and the remainder of his life was spent in that city.

When he was about 15 years old, Martín was apprenticed to a barber surgeon. In 1601 he became a Dominican oblate, his first duties being to care for the sick friars in the monastery of Santo Domingo. It was not customary at that time to permit a mulatto to enter a religious order in Peru, but because of the exceptional qualities and virtue exhibited by Martín, he was ordered to become a lay brother in the Dominican Order in 1610. As a friar, Martín was noted for his kindness to all persons but especially to the poor and the unfortunate; animals also found in him a friend of rare understanding. His greatest sympathy was won by the youth of Lima, for whom he established an asylum and a school, considered by some to be his monument. He died on Nov. 3, 1639, was beatified in 1837, and canonized in 1962; his feast is celebrated on Nov. 5.

See Cyril Martindale, *Blessed Martín de Porres* (1920). (A. S. Tr.)

PORSENA (PORSENNIA), LARS, king of Clusium in Etruria (his name in fact may be derived from the Etruscan word for "king"), traditionally at the end of the 6th century B.C. According to the main Roman tradition he undertook an expedition against Rome in order to restore the banished Tarquinius Superbus to the throne. He gained possession of the Janiculum, and was prevented from entering Rome only by the bravery of Horatius Cocles (*q.v.*). Porsena then laid siege to the city, but was so struck by the courage of Mucius Scaevola (*q.v.*), that he made peace on condition that the Romans restore the land they had taken from Veii and give him 20 hostages. He subsequently returned both the land and the hostages.

Another version, however, derived from Etruscan sources, holds that the Romans were obliged to surrender the city, to acknowledge Porsena's supremacy, to abandon their territory north of the Tiber, to give up their arms, and in the future to use iron for agricultural purposes only. Modern historians have tended to put more be-

lief in this second account because the Roman version seems designed to conceal a defeat, especially in light of the fact that the Romans were required to give hostages. The traditional version, however, does account for several historical facts which seem curious if it is imagined that Porsena was entirely successful; e.g., the failure to restore the Etruscan dynasty, and Rome's speedy recovery from defeat. Otherwise it must be supposed, and this is not at all unlikely, that the invasion of the Etruscans under Porsena was, like the later sack of Rome by the Gauls, migratory rather than imperialistic. With the departure of Porsena all traces of Etruscan sovereignty disappear.

PORSON, RICHARD (1759–1808), one of the greatest of English classical scholars, was born on Dec. 25, 1759, at East Ruston, Norfolk, the son of a weaver. The vicar of the parish recognized his promise, gave him tuition, and interested the local gentry in him, so that he was able to go to Eton (1774) and subsequently to Trinity College, Cambridge (1778), of which he became fellow in 1782. In 1792 his fellowship came to an end, because he was unwilling to fulfill the statutory requirement of taking holy orders within seven years of his M.A. degree and the master of Trinity declined to appoint him to a lay fellowship which he had reason to expect. When his fellowship ceased his friends subscribed enough to produce an annuity of £100, and later in the same year he was appointed to the professorship of Greek at Cambridge, which then carried a salary of £40 and was virtually a sinecure.

From 1792 Porson lived in London, in chambers in the Temple. Among his friends was James Perry, editor of the *Morning Chronicle*, to which Porson contributed anti-governmental lampoons and *jeux d'esprit*, and in 1796 he married Perry's sister, Mrs. Mary Lunan. She died a few months after the marriage. For the last two years of his life Porson was for the first time in easy circumstances, with his appointment in 1806 as librarian to the London Institution with a salary of £200. He died in London on Sept. 15, 1808, and was buried in the chapel of Trinity College, Cambridge.

Porson drank to excess, was addicted to late hours, took no care of his health or his appearance, and could be rude and boorish in company. But there was an attractive, even a noble, side to his character. His friends delighted in his wit and learning and his store of anecdotes and quotations and admired him for his devotion to truth, his indifference to worldly success, and his readiness to communicate his knowledge to others. He had a remarkable memory, a love of literature ancient and modern, and a gift for satire and parody. But he was content for the most part to devote his talents to Greek scholarship (see CLASSICAL SCHOLARSHIP).

His earliest interest was Aeschylus. Shortly after taking his degree he began work on an edition, but the project was abandoned. In 1792 however he arranged for an edition to be printed by Andrew Foulis of Glasgow. In 1795 Foulis published a folio edition from his text without his consent, and in 1806 after long delays Porson grudgingly agreed to the publication of the octavo edition. His notes on the Suda lexicon were published as an appendix to the 1790 edition of J. Toup's *Emendationes in Suidam*. In the same year appeared the *Letters to Mr. Archdeacon Travis in Answer to His Defence of the Three Heavenly Witnesses*, 1 John v. 7, the substance of which had already appeared in the *Gentleman's Magazine*. In these letters, written with wit and polemical vigour as well as learning, Porson effectively demolished the case which Travis had put for the authenticity of a verse now universally acknowledged to be interpolated. In 1797 he published his edition of the *Hecuba*, intended as the first volume of a complete Euripides. In fact only three more plays were published, the *Orestes* in 1798, the *Phoenissae* in 1799, and the *Medea* in 1801. A second edition of the *Hecuba*, with an important supplement to the preface, appeared in 1802.

Porson was the most brilliant of the English school of scholars who, following where Richard Bentley had pointed the way, de-

voted themselves to the task of freeing the Greek texts from corruption. His work, though limited in range and in quantity, has a quality which raises him above his contemporaries. His special strength lay in his insight into Greek metre, his skill in emendation and his appreciation of the niceties of Attic diction. In the preface to the *Hecuba* he threw new light on the metres of Greek drama, and in particular enunciated "Porson's law," which forbids a break in the fifth foot of the iambic senarius after a long syllable (see PROSODY, CLASSICAL). As a textual critic he combined brilliance with carefulness, and many of his emendations have been accepted. He was scrupulously honest and interested only in discovering the truth; while he did not ignore manuscript evidence, he was mainly guided by his sense, at once instinctive and based on careful study, of Greek usage and versification. His work is marked by a sureness of touch and economy of expression which give the impression of effortless ease and conceal the learning and hard work which lay behind it.

Porson took a delight in calligraphy and was specially interested in Greek script. The admirably clear and readable Greek type which bears his name was long used by the English university presses.

BIBLIOGRAPHY.—Reviews and minor works ed. by T. Kidd, *Tracts and Miscellaneous Criticisms of Richard Porson* (1815), which contains bibliography of his works, including publications of other scholars to which he contributed notes; unpublished notes and emendations ed. by J. H. Monk and C. J. Blomfield, *Adversaria* (1812), and by P. P. Dobree, *Notae in Aristophanem* (1820). *Correspondence* ed. by H. R. Luard (1867). See also J. S. Watson, *Life of Porson* (1961); M. L. Clarke, *Richard Porson* (1937), with bibliographies; D. L. Page, "Richard Porson," *Proceedings of the British Academy*, vol. xlv (1960). (M. L. Cr.)

PORT, a place where goods, passengers, and mail are transferred to, from, or between water carriers. Nearly all ports include portions of one or more harbours where the configuration of the shore, either naturally or with artificial improvement, offers protection to vessels. A harbour may serve a single port or, as in the case of a large harbour such as San Francisco Bay, several ports; a port may be served by a single harbour or, as in the case of the Port of Chicago, by several harbours. Ports are gateways leading to and from inland areas. The connections—by railway, highway, pipeline, airways, and inland waterways—between ports and their hinterlands are vital to port development and operation. Because the handling of goods and servicing of vessels at ports require large labour forces, ports are usually associated with cities.

In addition to the organizations, public and private, that are directly responsible for operating a port, there are also many related organizations, including the carriers (ship operators, barge operators, railways, and so forth), storage agencies, shippers and receivers of freight, export agents, ship brokers and agents, foreign consuls, and financial institutions. In addition, there are many specialized types of services associated with ports, including ship repairmen, oil and coal bunkermen, ship chandlers, and others. Many industries located along waterfronts are dependent wholly or largely upon the port for the receipt of their raw materials or for the shipment of their products. Other industries depend upon the port-oriented labour force as part of their markets.

The primary object of port development and operation is to move traffic through the port with maximum speed and efficiency. Other things being equal, larger ports, with a greater variety of services, will offer the shipper greater frequency of ship sailings and will produce sufficient traffic to justify a large number of calls by ships. The volumes of cargo and of ship services are therefore reciprocally related, assuming a satisfactory level of efficiency in the transfer of goods and in related paper work within the port. An important measure of port efficiency is the "turnaround time," the time a vessel spends in port, including the time required for it to move from the harbour entrance to its berth, to discharge its cargo, to take on fuel and cargo, and to move out to the entrance of the harbour. Paralleling vessel turnaround time is the time required to handle goods in the port area—the time that elapses between the arrival of goods in the port area and their departure. A port with a good harbour and with adequate physical equipment and port services will attract traffic from a hinterland that is served by competitive ports, even though inland distances

and inland transportation rates may be somewhat disadvantageous. Port competition, in many regions, is intense, and most of the major port organizations maintain extensive trade development and promotional activities. In addition, favourable inland transportation rates between ports and their hinterlands are of vital importance, not only in port competition, but also in many instances in the determination as to whether traffic will move overseas in the first place. Securing favourable rates for shipment via inland carriers to and from the ports, therefore, constitutes a major activity of many port agencies.

Port Location.—The location of a port is a major factor relative to its economic functions. Geographers consider location in terms of site and situation. Site refers to the characteristics of the area occupied by the port, including the harbours and adjacent landward areas. Situation refers to the relations of the port to its hinterland and to the overseas areas with which the port has connections. (The latter is sometimes called the "foreland" of the port.)

Site.—Among the important site characteristics of a port are the existence of adequate protection from open water, an entrance wide enough and deep enough for the largest vessels, a sufficient depth of water in the harbour to permit its use by vessels of deep draft, a climate that does not present unusual difficulties, shorelines with level areas and good foundations for buildings, and land transportation facilities. Few ports have all of these characteristics, but in many instances extensive modification of the natural conditions is possible by dredging, building protective breakwaters, and using electronic aids to navigation. Most modern ports used by large oceangoing ships have minimum depths of from 30 to 35 ft. (9.1 to 10.7 m.) at low tide in their entrance channels and alongside the principal terminals. A typical 10,000-ton dry-cargo vessel will have a draft, fully loaded, of from 28 to 30 ft. (8.5 to 9.1 m.), large passenger liners up to 38 ft. (11.6 m.), and supertankers as much as 50 ft. (15.2 m.). A safety margin of up to 5 ft. (1½ m.) must be allowed under the keel of the vessel because the draft increases by about 1 ft. for each degree of roll.

The simplest type of harbour is an open roadstead in which the shoreline offers little or no protection from winds and waves. Where the direction of the wind and waves is rather constant, an open roadstead to the lee is usable most of the time; among examples of this type are many ports on the west coast of South America and the west coast of Africa. When strong winds or heavy seas from other than an offshore direction occur, vessels must "lay to" and are not free to load or discharge cargo. At most open roadsteads, loading and discharging is done by means of lighters—small, shallow-draft vessels that can tie up to wharves having insufficient depth alongside for the larger ships. The use of lighters involves extra handling of the cargo, and thus extra time and expense; if any substantial volume of traffic develops at such a port it becomes necessary eventually to seek an alternative location for the port or to provide an artificially protected harbour by construction of breakwaters. Until 1914, along the 300 mi. (480 km.) of the Ghana (then Gold Coast) coastline there were no fewer than 30 open roadsteads where trade was carried on. Their grave disadvantages led to the creation in 1928 of the artificial harbour of Takoradi and later Tema, east of Accra. After 1952, at Tema three miles of moles were built to create a harbour area of 500 ac. (200 ha.) with a depth of 42 ft. (12.8 m.). In 1961 an eight-berth deep-water harbour at Tema was opened. With the development of supertankers during the 1950s with drafts in excess of the available depths at many of the harbours where they operate, loading and discharge of the liquid bulk cargoes commonly takes place in open roadsteads through submarine pipelines, the vessel anchoring or tying up to pilings or other offshore structures, as at Persian Gulf and southern California ports.

Many ports are located on estuaries, the lower portions of river valleys that have been drowned by geological changes in the relative levels of land and sea. In the case of estuaries with relatively narrow entrances and wide expanse, such as Chesapeake Bay, the tides are distributed throughout the estuary with the result that the daily tidal range is small and the adaptation of shoreline

terminal facilities is relatively simple. Where the estuary has a wide entrance and gradually narrows, as in the case of many of the estuaries of the British Isles and northwestern Europe, as well as the Bay of Fundy, the tides are accentuated; the great tidal range necessitates the provision of various devices to keep a relatively constant level between the vessels and the shoreside facilities. At ports such as London, Liverpool, Le Havre, and Antwerp, large basins are artificially provided, separated from the tidal estuary by locks. These basins can be provided economically only where the shores are relatively low, and where soft, unconsolidated materials permit easy excavation for dock construction. The locks—sometimes called “wet docks”—that connect the basins with the estuaries usually have two sets of gates that permit the water level within the lock to be adjusted to the stage of the tide outside. If the lock gate is single, vessels can move in and out of the wet dock only when the stage of the tide in the estuary is the same as the level of water inside the basin. The provision of basins is also necessary in ports where a large tidal range induces strong tidal currents. At Liverpool, with a tide rise of 27 ft. (8.2 m.), currents with velocities up to 6 knots occur in the Mersey; this would make the handling of cargo on an open wharf a difficult operation. Because of delays in movement of vessels in and out of the basins, many estuary ports that handle a substantial volume of passenger, mail, and express freight traffic have, in addition to the terminal facilities along the sides of the basins, landing stages or floating terminals outside the basins. These facilities, connected to the shore by means of ramps or bridges, maintain a constant level relative to the vessels. Among the best known are the St. Pauli landing stage at Hamburg, the Princes landing stage at Liverpool, and the landing stage at Tilbury, near London. Similar floating structures, known as wharfboats, are utilized in rivers where the fluctuations in water level are great, as, for example, along the Ohio and Mississippi, where many of the major barge terminals are on floating structures.

Many ports on rivers and canals, where the changes in water level are not great, are provided with artificial basins not separated from the river or canal by locks. These are called “tidal basins” or outer basins, and are entered directly from the river. Commonly they are designed with entrances so located as to enable vessels to enter or leave without the necessity of turning sharply, thereby, in some instances, eliminating the use of tugs. Among ports of this type are Rotterdam, Hamburg, Bremen, Glasgow, Manchester, and Stockton (Calif.), as well as many of the ports along the Rhine not accessible to seagoing ships, such as Düsseldorf, Duisburg-Ruhrort, and Basel.

Many ports, including those accessible to deep-draft oceangoing ships as well as those accessible only to inland craft, are developed with marginal wharves, parallel to the shore, alongside which vessels tie up. Among the deep-water river ports with marginal wharves are New Orleans and Albany (N.Y.), the former in the lower reach of a river, and the latter at the inland head of navigation for ocean ships.

Finally, many ports consist of artificial harbours protected by breakwaters. These include Long Beach (Calif.), Marseilles, Naples, a major part of the harbour of Genoa, and many of the important harbours of the Great Lakes including Chicago, Calumet Harbor, Milwaukee, and Cleveland.

Many of these artificial harbours have been constructed in areas where natural conditions are unfavourable and yet a port is desirable. The packet station of Dover, because of its situation close to the continent of Europe, has been built of necessity on an unfavourable site. Political considerations have also led to the creation of artificial ports in situations not wholly favourable. The partition of India in 1947 meant that the isolated East Pakistan could no longer rely on Calcutta as its port. Chittagong had to be developed even though it lay 12 mi. (19 km.) up the Karnaphuli River, a winding estuary with a large tidal range, very strong currents, and a bar at its entrance. Chittagong and the more recently developed port of Chalna handle all the trade of East Pakistan, even though the natural outlet is Calcutta.

Large ports commonly include combinations of several of the above types of configuration. The Port of New York, for exam-

ple, includes development along several rivers and bays with marginal wharves, artificial basins, piers, and slips. Tyneside, extending for 10 mi. (16 km.) from Newcastle to the sea, has numerous river wharves, side channel staithes for coal loading, closed dock basins, and protective breakwaters at the river mouth.

Situation.—The situation of a port involves considerations of its location relative to the port hinterland and to the open waters of the sea or of major lakes. Since ships and inland waterway barges are the most economical form of transportation for most goods, it is advantageous to carry the goods for the maximum possible distance by water, on the largest possible vessel, assuming the volume of traffic to be sufficient to employ large vessels. Ports, therefore, tend to develop as far inland as the large vessels can operate. An additional advantage of such a location is that an inland port can command a hinterland in every direction. For these reasons, many of the major ports of the world are located at considerable distances from the sea, in spite of the necessity of expensive construction and maintenance of waterways leading to the port. Houston, Tex. and Manchester, Eng. are connected with the sea by artificial waterways. Albany is at the head of a 150-mi. (241 km.) artificially deepened channel in the Hudson River. The St. Lawrence Seaway (*q.v.*) was constructed to open up a waterway to Chicago and Duluth, each more than 1,000 mi. (1,600 km.) from tidewater and over 2,000 mi. (3,200 km.) from the ocean.

On the other hand, it is frequently advantageous, especially in the case of passengers, mail, and high-class cargo, for a shipper or traveler to take advantage of the higher speed of inland transportation for the maximum possible distance, and for the vessel operators, particularly those operating regularly scheduled liner service, to receive the benefit of shorter voyages and more round trips per year resulting from the use of ports closer to the sea. Many ports that are some distance inland have outports closer to the sea, the latter generally specializing in passengers or high-class cargo. Thus Hamburg's fast transatlantic service is mainly via Cuxhaven, Bremen's through Bremerhaven. Much of London's liner traffic is actually handled at Tilbury, some 30 mi. (48 km.) seaward. Although Houston handles a considerable volume of liner traffic, Galveston is still a major port. The development of Albany has not had any major effect upon the Port of New York as the principal U.S. port for transatlantic liners. In spite of the development of the St. Lawrence Seaway, nearly all passenger vessels and many cargo liners proceed no farther up the St. Lawrence than Montreal.

The situation of an inland port, although generally advantageous with respect to access to a maximum hinterland and to minimum overall transportation cost between inland origin or destination and overseas, is nevertheless not an unmixed blessing, for the costs of providing and maintaining an inland waterway route in order to have access between the port and the sea may be more than the port traffic would economically justify. With the trend toward larger vessels, and especially for deeper draft, many ports that were adequate for the oceangoing ships of an earlier day can no longer be reached by large modern ships. Many such ports have declined and have been replaced by newer ports closer to the sea. Avonmouth has developed as an outport for Bristol as the largest vessels found it difficult to navigate the shallow and twisting River Avon in order to reach the city. Other ports have declined because of failure to keep the access channels dredged to sufficient depth for modern vessels; in still others the entrances have been allowed to shoal so that the harbours are no longer useful. On the southeastern coast of England many of the former Cinque Ports such as Sandwich and Rye have ceased to be important for this reason.

Functional Classification of Ports.—Ports may be classified as comprehensive, commercial, or industrial, according to the types of traffic they handle. Most major world ports are comprehensive, handling both a diversity of types of cargo and considerable passenger traffic. In such ports, however, the various facilities tend to be specialized in character; some are designed for handling general cargo (with or without passengers) and others for one or more types of bulk cargoes. General cargo consists of discrete

packages or items, such as bales, boxes, crates, machines, etc., which vary in size, shape, and weight, and which require considerable labour in their handling. Bulk cargoes include ores, grain, and liquids such as petroleum and vegetable oils; they may be handled by gravity, suction, or grab buckets, and their handling is generally highly automated. Liners operating on regularly scheduled services tend to emphasize general cargo, although they may also carry some bulk cargo; most bulk cargoes are carried on tramp ships or industrial vessels not operating at regular intervals in scheduled service. Ports that emphasize general cargo and liner services are usually classified as commercial ports, and those that handle mostly bulk cargoes are industrial ports. A comprehensive port is one that handles both types of cargo regularly and in considerable volume.

Important commercial ports are served by many shipping lines connecting the port with many regions of the world. For example, the Port of New York has approximately 175 shipping lines in berth service operating at regular intervals, New Orleans has about 125, and Chicago and other U.S. Great Lakes ports have about 50. Usually a major comprehensive or commercial port will have several competitive lines serving each of the regions with which it has substantial traffic, so that the shipper using the port has a choice of frequent sailings. The frequency of shipping service constitutes a major consideration in the development and expansion of a port. Ports that can offer, in addition to general cargo, bulk cargoes such as grain to fill out the unused space or weight capacity of liners offer additional inducements for liner services and may grow at the expense of ports not offering such bulk traffic. Many general cargo piers and wharves at ports such as Boston, Philadelphia, Baltimore, New Orleans, and Montreal offer direct access to grain elevators by means of conveyor belts so that vessels can load grain at the same time that they load general cargo. In addition, pipelines at some ports connect the general cargo berths with liquid bulk storage facilities so that vessels may load and discharge such commodities as vegetable oils concurrently with the loading or discharge of general cargo.

In many parts of the world industrial ports have been developed to serve centres that produce raw materials, foodstuffs, or fuels. If such centres are located inland, rail, pipeline, or highway connections are provided to transport the commodities to the port area. Such single-commodity shipping ports include, for example, the many oil ports of the Persian Gulf area, some of which are pipeline terminals and others refinery locations. Along the coasts of South America and Africa are many ports designed for the purpose of shipping the output of individual mines or groups of plantations. On the coast of New South Wales in Australia, Port Kembla grew out of an open roadstead to export coal from mines in the vicinity. Much later San Lorenzo in Ecuador was developed to export the banana crop. In and near the major population centres and consuming regions of the world, on the other hand, industrial ports may serve specific industries, such as the steel mills at Gary, Ind., or they may serve many industries that receive or ship bulk traffic. At most industrial ports in the manufacturing areas a high proportion of the traffic terminates at plants along the waterfront, requiring no further inland transportation prior to processing. Industrial establishments requiring direct waterfront access for transportation purposes generally need very extensive land areas. Most such plants have highly developed specialized facilities for large-scale handling of bulk commodities. A special type of port mainly confined to western Europe is the packet station. Dover, Calais, Holyhead, Harwich, and Esbjerg are ports which fall into this category. Often they have been built on unfavourable sites simply because shortness of sea crossing was an overriding factor. Thus most of the harbours are entirely artificial with breakwaters, as at Dover and Holyhead, creating a deep-water harbour. This allows vessels to enter and leave at all states of the tide, an essential requirement in the maintenance of a regular sailing timetable. The packet station must also have good internal communications, and for this reason many have been developed by railway companies. Parkeston Quay at Harwich, Heysham in Lancashire, and Newhaven in Sussex are all owned by the British Railways Board.

Hinterlands and Freight Rate Structures.—There usually

is strenuous competition for the business of port hinterlands. The principal exceptions are those of ports that export bulk cargoes and were developed for the specific purpose of serving one or more inland establishments such as mines, logging camps, plantations, etc. Each of the major industrialized regions of the world is served by many ports, all in competition with each other. The major factors determining the success or failure of a port to capture traffic of a competitive hinterland are the inland freight rates and the quality of service provided by the port. Quality of service refers to the frequency of sailings, the landward connections, and the number and efficiency of the organizations performing either physical handling of goods or paper work in the processing of shipments moving through the port.

Few large ports can exist for very long if they handle only the traffic of their own metropolitan areas. Ports are essentially gateways, and the cost and efficiency of inland transportation between port and hinterland are basic considerations. Even within the port city or metropolitan area the competition of other ports is often felt. For example, ports such as Philadelphia, Baltimore, and Boston have fewer scheduled liner sailings than New York. Often the same vessels call inbound at New York before (and outbound after) making calls at Philadelphia, Baltimore, or Boston with the result that these cities have difficulty in attracting shipments to and from their own metropolitan areas in competition with New York.

The integrated trading unit of the European Economic Community (EEC) created a vast economic hinterland stretching far into the interior of the continent and for this reason a new port, Europoort, was built on the North Sea coast of the Netherlands 18 mi. (29 km.) downstream from Rotterdam. With good internal communications provided by the Rhine, its tributaries and associated canals, a close railway network, and an extensive pipeline system, Europoort seemed destined to become the foremost port in the world. By 1963, although by no means complete, its cargo trade (including Rotterdam's) already exceeded that passing through New York. Europoort is unique in that it has been planned independently from an existing urban area and will rely heavily on its hinterland at the outset, although in time it will establish its own industrial estate.

In regions such as North America and western Europe that have extensive networks of inland transportation, many ports compete for the traffic of a common hinterland, on the basis of a combination of relative rate advantages and quality of service. In many instances, rates through groups of ports are equal, or nearly equal. For example, rates on many items to and from the midwestern United States are equal through North Atlantic ports from the Canadian border to the Virginia Capes, and these in turn are equalized with inland rates to and from Southern Atlantic and Gulf of Mexico ports. Until 1963, Philadelphia, Baltimore, and other "outports" had inland rates below those through New York; earlier, rate equalization through the various so-called North Atlantic Range ports had been a major issue before government regulatory bodies. Ocean rates are commonly equalized for all ports of a range, but ports within that range may have different inland rates. On the other hand, several ranges of ports may compete for the traffic of a common hinterland, as for example, in the case of the midwestern United States, in which ports of the Great Lakes, the North Atlantic Range, and the Gulf Coast are in competition for the available traffic. Similarly, in much of west central Europe, ports of the Mediterranean and of the Bordeaux-Hamburg Range are in competition with each other.

In addition to the basic inland rates there are many other rate items in which ports compete for hinterland traffic. For example, "free time," i.e., the number of days allowed by the inland carriers between arrival of the shipment at a port and the unloading from the railroad car, truck, or barge, may differ among the various ports or ranges of ports. Some ports, such as New York, have many of their terminals across water from their major hinterland areas, and the absorption of transfer or lighterage charges may be an important consideration in enabling such ports to compete with other ports not having such a physical disadvantage. Another important consideration is the availability of inland waterway transportation at some ports, tending to give the ports so favoured a cost

advantage over those not having inland waterway connections.

Port Organization and Finance.—There are many different types of organizations that construct and operate ports and port terminals. Some ports are completely owned by governments; others are completely built, owned, and operated by private industries to serve their own needs; still others represent combinations of public and private ownership and operation. Most of the world's harbours are improved and maintained by governments while the shoreside terminal facilities may or may not be publicly owned and operated. In the United States most harbours and waterways are improved and maintained by the federal government, with actual construction and maintenance by the Army Corps of Engineers, either directly or through employment of civilian contractors. Provision of terminal facilities, as well as dredging alongside the waterfront terminals, is a local responsibility. In Canada many of the major harbours are maintained by the Department of Transport, which also operates some terminal facilities, although most are under private operation. In Great Britain there is a diversified pattern of ownership and operation, with some harbours and terminal facilities owned, maintained, and operated by public authorities and others by private business. In London, the Thames-side terminals are in diversified ownership but the major basins are owned, maintained, and operated by the Port of London Authority. The worldwide tendency during the 20th century has been toward increased public ownership of port terminal facilities.

Although most harbours in the United States are maintained and improved by the federal government, there is no uniform pattern with regard to the terminal facilities, and in most of the larger ports, including New York, Boston, Philadelphia, Hampton Roads, New Orleans, Houston, San Francisco, Portland, and Seattle, as well as in such Great Lakes ports as Chicago, Cleveland, and Toledo, terminal facilities are partly publicly owned and operated, partly publicly owned and privately operated under contract or lease, and partly privately operated. In many ports, such as the larger ones on the eastern seaboard, extensive waterfront facilities are owned and operated by railroads that offer free or low-cost berthage to vessels that supply the owner lines with traffic. In some instances, as at the ports of New York and Chicago, more than one public authority owns or operates port terminals, with little if any coordination in planning, development, or operation.

Public authorities that are concerned with port development and operation may be municipalities, counties, special port organizations, or states. Examples of municipally owned and operated facilities in the United States are those of the Milwaukee lakefront. In New York, the city owns and operates some facilities, and it leases many city-owned facilities to railroads, steamship companies, and terminal companies for operation. An example of a county-owned facility is that of Port Everglades, Fla., which was developed by the Broward County Port Authority. Los Angeles and Long Beach have many municipal port terminal facilities, some of which are leased for operation while others are operated directly by the municipal port authorities. Among the examples of state-owned port terminal facilities are those in Mobile, Ala., Wilmington and Morehead City, N.C., and several in San Francisco.

Public terminal facilities are rarely self-liquidating, but their construction and operation are usually justified by the indirect economic benefits they create. The deficits are charges against the tax base of the community, and the facilities are commonly financed by general obligation bonds, backed by the faith and credit of the governments concerned. Some of the specialized port agencies where the facilities have good prospects of being self-liquidating are financed by revenue bonds that are retired by rental of the facilities to private operators or, in the case of public operation, by charges made directly against the traffic that uses the facilities. One advantage of the specialized port agency, independent or partly independent of the general government, is its freedom to incur debts beyond the legal debt limit of the city, county, state, or federal government, for purposes of building, acquiring, leasing, and operating the facilities. In many instances the revenues of the port agencies are insufficient to cover amortization, interest, depreciation, and operating expenses, so that public

subsidy is required. In other instances, the port authority is really a general transportation authority, as in the case of the Port of New York Authority, which operates a variety of highway and inland terminal facilities, including airports, truck terminals, and bus terminals in addition to purely maritime facilities. Some ports are under unified public ownership and control; others have several or many owners, both public and private, making difficult the overall planning and development of the port where diversified ownership creates conflicts of interest. (H. M. M.)

Port Authority.—A port authority is a corporate body providing terminal facilities and services for shipping at one or more ports. The constitution of, and the functions exercised by, port authorities throughout the world vary considerably from port to port, the functions being to some extent dictated by the trade of the port. In all cases the port authority provides facilities, and while there are differences in the extent of facilities provided, the main differences lie in the services provided. At some ports, such as Haifa and the Manchester Ship Canal, the port authority itself exercises substantially all the functions within the port, but in the majority of cases the port authority exercises only limited functions. In New York and Liverpool, for example, the port authority provides certain facilities and certain services, but the loading and unloading of ships is carried out by stevedores and master porters.

In many cases, of which London and Antwerp are examples, in addition to the control and operation of the terminal facilities, the port authority is responsible for the maintenance and improvement of the approach channels and navigational aids therein, including radar, whereas in the United States, Germany, and the Netherlands the government is responsible for the approach channels and navigational aids and the port authority is not directly concerned. In some cases the port authority is also the pilotage authority, but in other cases the pilotage services are provided by an independent body and in many ports the towing facilities are provided by private companies.

The form and constitution of a port authority vary considerably from a port controlled by a government department to a port owned and operated by a private company. Ghana offers an example of government-controlled ports; all ports in the country are under the jurisdiction of the government, the actual operation being carried out by an official appointed by the president. There are also ports that are owned and operated by government agencies. The British Transport Docks Board owns and controls a number of ports in the United Kingdom, including the docks at Southampton; other examples are the Nigerian Ports Authority and the National Harbour Board in Canada. In these cases the government usually retains the right to enable a minister, after consultation with the port authority, to give the port authority directions of a general character as to the discharge of their functions in relation to matters appearing to the minister to affect the public interest, and the port authority is required to give effect to any such directions. The members of these port authorities do not usually include direct representatives of port users.

In the case of the Port of New York, agreement was reached in 1921 between two adjoining states, New York and New Jersey, in the form of an interstate compact approved by Congress, to create the Port of New York Authority. It was described as "the municipal corporate instrumentality of the two States for the purpose of developing the port." The compact proclaimed the purposes of the Port of New York Authority to be the protection and promotion of the port's commerce and the development of terminal and transportation facilities within the port.

In many cases the local municipal authority is responsible for the operation of the port within or adjoining its area. Antwerp, Rotterdam, and Bristol are examples of this type of port.

The method widely adopted in the United Kingdom in ports such as London and Liverpool and followed in many parts of the Commonwealth such as in Calcutta, Bombay, and Singapore, is to set up by statute an independent port authority to operate as a public trust. Such a port is operated for the benefit of port users; the port authority borrows its money at fixed rates of interest and does not make a profit in the accepted sense of the

term; any surplus of revenue over expenditure is used to improve the port facilities or to reduce the port charges. While the composition of a public port authority varies according to local circumstances, in the main it consists of members elected by the users of the port with a limited number of members appointed by government departments to represent the national interest or by particular interests such as local authorities interested in the operation of the port. A small minority of ports are controlled by public and private companies, the Manchester Ship Canal Company being an example of the former while the Port of Granton in Scotland is an example of the latter. (T. A. McL.)

Site Requirements.—Most of the facilities immediately related to the waterfront in a modern port are such that more and more land is required for their successful operation. Bulk carrying vessels have increased rapidly in size, while general cargo carriers, including cargo liners, have also been growing larger. This means that vessels, because they represent much greater investments than formerly, must turn around faster. The result is concentration of more cargoes per berth-day. This creates a demand for more space on shore to handle the inbound and outbound cargo movements. To meet this demand, transit sheds are larger than formerly, and warehouses, open storage areas, railroad yards, and truck terminals must be proportionately larger. Demands for extensive land areas now exceed the demands for increased numbers of berths in many ports. Larger vessels and faster turn-arounds mean that more cargo is handled with fewer ships. The tonnage of ships has increased much more rapidly than has the length of required berthage. The larger general cargo ships require about 600 linear feet (183 m.) per berth as compared with about 450 feet (137 m.) for a ship with half the capacity. At many ports the piers are much wider than formerly to increase the land area per berth, and the marginal wharf or quay is increasingly favoured over the traditional pier with its tendency toward congestion at the landward end.

An increasing proportion of freight arriving at and departing from ports is handled in motor trucks, and at most general cargo terminals the volume of truck movement far exceeds that by rail. New requirements for expeditious highway access to and egress from the port areas, free from landward congestion, have also increased the demand for more extensive sites for port terminal areas.

Because of these demands for more land, new and more extensive facilities have been built near many ports beyond the periphery of the built-up congested area of the port city, where extensive sites on lower-cost land, relatively free from nearby congestion, could be acquired. Thus, at the Port of New York, major developments at Newark and Elizabeth have been created. In San Francisco Bay, extensive developments at Oakland on the mainland have offered competition to the older piers of San Francisco. At Chicago, extensive terminal facilities have been built in the Calumet area, 15 miles (24 km.) from downtown Chicago. In Baltimore, Philadelphia, and many other ports the newer and more modern facilities are located on extensive tracts at considerable distance from the central parts of the cities, generally seaward, to facilitate vessel movement, while the older port terminals are relatively little used or their sites are converted to other uses.

Methods of Handling General Cargo.—While mechanization has been characteristic of bulk cargo handling for many years, general cargo handling at waterfront terminals has been automated much more slowly, and ports that handle large amounts of general cargo require a large waterfront labour force. The variety of sizes, shapes, and weights of the items that constitute general cargo has been a major difficulty inhibiting the greater use of mechanized cargo-handling methods, but during the 1950s many ship and terminal operators greatly extended the use of labour-saving devices. One of the most important new developments was the "roll-on-roll-off" technique by which loaded semi-trailers were driven on board at the port of embarkation and driven off at the port of debarkation. The standardized container was the next step, eliminating need for transportation of the trailer wheels. The containers are handled either by special crane and elevator equipment or by "roll-on-roll-off" methods involving use of ramps.

These maritime techniques were paralleled on shore by the railroad "piggyback" system in which motor truck trailers or other standard units were loaded aboard railroad flatcars. The integration of land and water container movement offered potential labour savings of considerable magnitude at the waterfront.

In spite of mechanization, general cargo at most ports continues to be handled largely by traditional methods. At many European ports, and at ports elsewhere that follow European practices, it is customary to load and discharge cargo by cranes on the wharf, which raise or lower the cargo through the vessel's hatches. The cranes move the cargo between the ship and either a railroad car or a truck on the wharf. At the same time, the ship's gear, consisting of booms with capacity of upward of 3 tons each, moves cargo between the vessel and inland barges or lighters on the opposite side of the ship from the wharf. Floating cranes and floating grain elevators may also be used at shipside for transfer between ocean-going and harbour vessels.

The widespread use of mechanical equipment in general cargo handling has produced changes in the design of the general cargo terminals. A typical facility, whether on the side of a pier or along a marginal quay, consists of a bulkhead, behind which is a wharf apron, varying in width from 20 to 50 ft. (6 to 15 m.) but tending toward increased width in the newer installations, with railroad track and pavement permitting direct transfer between ship and railroad car or motor truck and the use on the apron of forklifts and other mechanical devices. There are also transit sheds, with heavy floor-loading capacity, usually of one story, permitting stacking of goods up to 20 ft. (6 m.) in height. On the opposite side of the transit shed are railroad tracks and paved truck-loading bays with an apron at car-floor height. This type of layout permits uninterrupted movement horizontally and use of the most efficient mechanical devices.

At most U.S. ports wharfside cranes are not common, except for special heavy lifts. The ship's tackle is usually used to move cargo to and from the vessel's hold, in most instances supplemented by floating cranes or other special equipment for heavy lifts. Ordinary general cargo is usually handled in slings of steel, wire, or rope. These slings form double loops that are attached to a cargo hook at the end of the ship's tackle. Since World War II the use of pallets—wooden platforms upon which the cargo is stacked both for storage and for movement to and from the ship—has become widespread. The use of pallets results in the saving of floor space in warehouses and transit sheds and permits the use of forklift trucks. Since pallet-loads can be assembled with greater efficiency than an equivalent volume or weight of individual items of cargo, substantial labour savings result.

These technological innovations in waterfront handling of general cargo have reduced the amount of labour required and thus have met with resistance from the organizations representing longshoremen and other dock workers. Waterfront labour difficulties have plagued ports for many years. Much of the trouble springs from the casual nature of many waterfront occupations, for the day-to-day fluctuations in demand for many types of waterfront labour are great, depending upon the volume of traffic to be handled in the port. This condition is reflected in the organization of the labour force into strong unions and in the regulation of hiring at the larger ports. Jurisdictional disputes among waterfront labour unions have caused difficulties at many ports. In 1953 the Waterfront Commission of New York Harbor required registration of all longshoremen and eliminated many of the former abuses in hiring practices. But in New York, as in many other ports, the introduction of automation in the handling of general cargo continued to be a major issue. (H. M. M.; A. H. W. R.)

PORTA, GIACOMO DELLA (c. 1537–1602), Italian architect whose work represents the development in style from late mannerism to early Baroque, was born and died at Rome. He was the chief Roman architect during the latter third of the 16th century. Della Porta continued two of Michelangelo's greatest architectural projects, the Piazza del Campidoglio and St. Peter's in the Vatican at Rome, whose dome, with a more pointed profile than Michelangelo intended, became the prototype of the Baroque dome. In a similar manner the facade he added to Giacomo da

Vignola's church of Il Gesù at Rome was the model for the typical Baroque church facade. (D. R. CN.)

PORTA, GIOVANNI BATTISTA DELLA (1535–1615), Neapolitan natural philosopher, an investigator into many fields of science, and also the author of some of the best Italian comedies of his age. His main work, *Magia naturalis*, was first published in 4 books (1558), but was enlarged to 20 in the second edition (1589). In this work he appears as a supporter of Renaissance animism, shows no belief in a systematic order in nature, and confines his observations to extraordinary natural phenomena. He considers magic as a "practical part of natural science"; i.e., as a technique to be acquired in order to control natural phenomena. The book discusses many problems and includes a confutation of demonology, a treatise on magnetism, and observations on the camera obscura, for which he was one of the pioneers of the use of the lens. His other works include: *De furtivis literarum notis: vulgo de ziferis* (1563), which shows his cryptographic abilities; *Arte del ricordare* (1566; Latin text, *Ars reminiscendi*, 1602); *Villae* (1583–92), an agricultural encyclopaedia; *De humana physiognomonia* (1586); *De refractione, optices parte* (1593); *Pneumaticorum libri* (1601), augmented in the Italian translation, *De' spiritali* (1606), with a description of a steam engine anticipating that of Thomas Savery; *Caelestis physiognomoniae libri* (1601), a confutation of judicial astrology; and *De distillatione* (1608), containing various chemical discoveries. The Accademia dei Segreti, founded by him in Naples, was suppressed by the Inquisition; but in 1610 he took part in the reconstitution of the Accademia dei Lincei. He traveled widely in Italy, France, and Spain, but died in Naples on February 4, 1615.

Though their plots derive from Plautus, from Italian *novelle*, and from earlier Italian plays, Della Porta's comedies clearly reflect contemporary life. Their dialogue is amusing and the characters are full of vitality. There is a modern edition of them, by V. Spanpanato, in two volumes (1910).

PORT ADELAIDE: see ADELAIDE.

PORTADOWN, a municipal borough (charter granted, 1947) in County Armagh, N.Ire., lies on the River Bann 26 mi. (42 km.) SW of Belfast by road. Pop. (1951) 17,202; (1961) 18,609. An important road and railway junction, Portadown owed its origin to a ford on the river. Its wide Market and High streets are overlooked by the parish church of St. Mark (1824) with its war memorial tower. Fine business thoroughfares stretch from the town centre, and there is a spacious covered market. The Town Hall (1890) and Carnegie Library and Museum (1903) are on Edward Street.

Portadown has a college, two secondary intermediate schools, and a maternity hospital. There is an annual music and drama festival. Two parks cater to most sports. The main industries are linen weaving, pottery, iron founding, bacon curing, flour milling, fruit canning, and the manufacture of lace, furniture, clothing, carpets, and metal cans. The renowned McGredy rose nurseries are located there. (W. H. W.)

PORTALES, DIEGO JOSÉ VICTOR (1793–1837), Chilean politician and *caudillo*, was born at Santiago on June 26, 1793. By 1824 he had built a profitable commercial firm that held a monopoly on tobacco in return for servicing a public loan contracted in England. When the Chilean government abrogated his contract, he threw himself into politics as an ultraconservative. In 1830 the conservative Joaquín Prieto became president, but Portales as chief minister ruled from behind the scenes and identified the objectives and defined the methods of the new power elite. He speedily silenced his liberal opponents, forced the military to submit to civilian dominance, and reestablished Chile's credit standing abroad. The constitution of 1833, which reflected his political doctrines, credited a highly centralized state controlled by and for the landed oligarchy and the Roman Catholic Church.

It provided 60 years of social stability and political order unequalled in Latin America. In 1836 he forced war on the Peruvian-Bolivian confederation in order to distract attention from his repressive domestic measures. He was assassinated at Valparaíso on June 6, 1837, while reviewing troops preparing to embark for Peru. Hated and feared alive, in death he became a hero around whom the Chilean people rallied to win the war in 1839. Chile then entered a period of aggressive nationalism and cultural flowering in the 1840s under Manuel Bulnes.

(J. J. J.)
PORTALIS, JEAN ÉTIENNE MARIE (1746–1807), French lawyer and statesman, one of the chief architects of the *Code Civil*, was born at Bausset in Provence on April 1, 1746. He practised at the bar of Aix and in 1778–81 was one of the assessors or administrators of Provence. In November 1793, after the First Republic had been proclaimed, he came to Paris and was promptly imprisoned as the brother-in-law of Joseph Jérôme Siméon, the leader of the Federalists in Provence. Upon his release he resumed practice in the capital, but in 1795 was elected deputy to the *Conseil des Anciens*, later becoming its president. As a leader of the moderate party opposed to the Directory he was proscribed at the *coup d'état* of Fructidor, and escaped to Switzerland. In 1800, when Napoleon became first consul, he returned to Paris and was appointed by Napoleon a *conseiller d'état* and a member of the commission charged with the drawing up of the *Code Civil*. As this body's most industrious member, he sought to permeate the code with the ideas of Roman law; many of the most important titles, notably those on marriage and succession, are his work. (See FRENCH LAW: *The Civil Code* [1804].)

In 1801 he was placed in charge of *cultes*, or public worship and was chiefly responsible for drawing up the provisions of the concordat between Napoleon and Pius VII. He entered the French Academy in 1806 and died in Paris on Aug. 25, 1807.

(L. N. B.)

PORTAL OF HUNGERFORD, CHARLES FREDERICK ALGERNON PORTAL, 1st Viscount (1893–), British air marshal and chief of air staff during World War II, was born at Hungerford in 1893 and educated at Winchester and Christ Church, Oxford. At the beginning of World War I he joined the Royal Engineers as a dispatch rider, and in 1915 he was commissioned in the Royal Flying Corps. He distinguished himself as a fighter pilot by shooting down several enemy aircraft; for this he was awarded the Distinguished Service Order and Bar and the Military Cross. Between the wars his posts in the Royal Air Force included those of commander of the British forces, Aden; instructor at the Imperial Defence College; and director of organization and air member for personnel at the Air Ministry.

In 1940 for a short time he held the appointment of air officer commander-in-chief, Bomber Command. Soon after he became chief of the air staff, the highest post in the RAF, which he held with great distinction until 1945. In addition to his duties at the Air Ministry, directing the policy and operations of the RAF, he took a prominent part in all the important Allied conferences as a member of the Chiefs of Staffs Committee. From 1946 to 1948 Lord Portal was responsible for work connected with atomic energy. He was appointed knight grand cross of the Order of the Bath in 1942, knight of the Garter, and to the Order of Merit in 1946. He was created a baron in 1945 and a viscount in 1946.

(E. B. BN.)

PORT ARTHUR, a city and seat of Thunder Bay District in southwestern Ontario, Can. is on Thunder Bay, a northwestern arm of Lake Superior. With its twin city Fort William (q.v.), it is known as the lakehead. Port Arthur is a major transportation centre on the Canadian National and Canadian Pacific railways and the Trans-Canada Highway. The passenger and freight ships of the Great Lakes transportation systems meet the rail lines of western Canada there.

There are important gold mines in the tributary area to the northeast. Extensive and rich hematite iron ore deposits at Steep Rock are tributary to the west, but most of the Steep Rock ore is shipped via special ore docks at Port Arthur. The city is noted for its large grain storage and shipment capacity.

There are extensive pulp and paper mills, shipbuilding and repair are important industries, and lumbering is a major activity. Pop. (1961) 45,276.

The Canadian lakehead is the gateway to a vast hunting and fishing area. (F. A. CK.)

PORT ARTHUR (Lŭ-shŭn), city and naval base in Liaoning province, China, at the southern extremity of the Kwantung peninsula of Manchuria. On the only part of the Manchurian coast line that is ice-free throughout the year, it occupies a strong strategic position, commanding the entrance to Po-hai wan, a gulf of the Yellow sea. Until the Chinese-Japanese war of 1894-95 Port Arthur was the chief Chinese naval base. It fell in 1894 to Japan, which was, however, forced to return it to China under European pressure. Russia was anxious to obtain an ice-free port for its Pacific fleet, and the capture of Chiao-chow (Kiaochow) by the Germans in 1897 provided the occasion for Russian ships to occupy Port Arthur and the near-by commercial port of Dairen (*q.v.*). In 1898, by agreement, Russia acquired from China the entire Kwantung peninsula for 25 years and the right to build a railroad to connect with the Trans-Siberian railway. Port Arthur was made an apparently impregnable stronghold.

During the Russo-Japanese War (*q.v.*), Port Arthur was the scene of a victorious Japanese siege from the landward that undoubtedly had considerable influence on the outcome of the war. In May 1904 the Japanese 2nd army landed at P'i-tzu-wo and gained control of the isthmus that connects the Kwantung peninsula with the mainland. Dairen was seized without fighting and its port was used to debark the Japanese 3rd army in June. The following month the Japanese broke through the outer defenses of Port Arthur and forced the Russians, under Gen. Anatoli M. Stössel, to withdraw to the main defense works of the base. Costly Japanese assaults were repeatedly frustrated during the next four months, until the key Russian position on 203-Metre hill was finally overcome in late November. The Russian garrison capitulated Dec. 20, 1904. Even before the start of the siege, the Russian far eastern squadron, consisting of 7 battleships, 7 cruisers and 25 destroyers, had been bottled up in Port Arthur by a blockading Japanese naval force and fell to the Japanese at the time of the capitulation.

By the Treaty of Portsmouth (1905) Port Arthur was transferred to the Japanese, who called it Ryojun. Japan retained control over the base and the entire Kwantung lease until the end of World War II. Soviet forces seized Port Arthur in Aug. 1945. By treaty arrangements with the Chinese Nationalists and, later, with the Communists, the Soviet Union secured joint Soviet-Chinese control over Port Arthur until 1955, when the naval base passed to exclusive Chinese Communist use.

Port Arthur became part of the joint municipality of Port Arthur-Dairen, known in Chinese as Lüshun-Talien, or simply Lü-ta, with its seat at Dairen. The population of Port Arthur in the 1953 census was 126,000; that of Lü-ta (1957 est.) 1,508,000. See also references under "Port Arthur" in the Index.

(T. Sp.)

PORT ARTHUR, a major deepwater port of east Texas, U.S., is on the northwest shore of Sabine Lake, 9 mi. from the Gulf of Mexico. The city is 16 mi. (26 km.) SE of Beaumont (*q.v.*) and 17 mi. SW of Orange (*q.v.*), the three points of the Golden Triangle, site of an important petrochemical industry. Pop. (1960) 66,676; Beaumont-Port Arthur standard metropolitan statistical area (Jefferson and Orange counties), 306,016. (For comparative population figures see table in TEXAS: Population.)

The area, known in 1840 as Aurora, was an important base for a considerable illegal African slave trade into Texas during the mid-19th century. In the 1890s Arthur E. Stilwell, for whom the city was named, decided to use the port as the southern terminus for the Kansas City Southern railroad which he was promoting. Stilwell bought 53,000 ac. of land in the area in 1895, organized a town and arranged in 1899 for the dredging of a deep-sea canal to bring vessels directly to the city's docks.

In 1901 oil prospectors discovered the remarkable oil well known as Spindletop a few miles from Port Arthur. This event marked the birth of the Texas oil industry. James Stephens Hogg,

a former governor of Texas, and the promoter and financier John W. ("Bet-a-Million") Gates stepped in to exploit the area and the port became a major sea outlet for a fabulous oil industry. Gates, in gratitude for a fortune made in the area, left the city funds for a library, art gallery, hospital, and an industrial college.

Port Arthur has a council-manager form of government, in effect since 1932. (E. W. F.)

PORT AUGUSTA, a port of South Australia, at the head of the 200-mi.-long (322 km.) Spencer Gulf. Though this position lends the port a potential importance, it is impaired by a shallow approach restricting ships to 8,000 tons. Fast, modern road and rail transport provides outlets for wheat and wool grown in surrounding districts. Port Augusta has changed its character from a pastoral outlet to an industrial town of some importance, with the Commonwealth Railways' workshops and two power stations (burning low-grade brown coal) and accompanying industries. Pop. (1961) town 9,711. The site was first discovered by Matthew Flinders in 1802 and in 1852 was named Port Augusta after the wife of Sir Henry Young, first civil governor of South Australia.

PORT-AU-PRINCE, capital, chief port, and commercial centre of the Republic of Haiti, situated on a magnificent bay at the apex of the Gulf of La Gonâve, which strikes inland for about 100 mi. between the two great peninsulas of the west coast, with its upper recesses protected by the island of Gonâve (30 mi. [48 km.] long and 2 mi. [3 km.] broad). Pop. (1961 est.) 239,000. The National Palace, rebuilt in 1918, the army barracks, and an imposing statue of Jean Jacques Dessalines dominate the Champs-de-Mars in the centre of the city. The most picturesque site is the Iron Market, where the merchants are almost exclusively women. Other notable buildings include the National Archives, the National Library, and the National Museum. It is the centre of the political and intellectual life of the nation and is the seat of the University of Haiti (established 1944), but Haiti's poverty makes the city one of the most unsanitary and backward capitals in the Western Hemisphere. During the U.S. occupation, 1915-34, sanitary conditions were improved. The climate is warm and humid, average 81° F (27° C) with little seasonal change.

Port-au-Prince is linked by railroad to Saint-Marc, about 45 mi. NW, and by paved road to Cap-Haitien; buses run on irregular schedules to all parts of the country. There are air services to most of the Caribbean islands and to New York. During the 1950s several luxury hotels were built to accommodate tourists. Textiles, cottonseed oil, flour and sugar mills are located in or near the capital.

The city was first laid out in 1749 by the French, and its bicentenary was commemorated in 1949 by an international exposition, the site of which is now a pleasant palm-fronted promenade. In 1751, and again in 1770, it was destroyed by earthquakes; in subsequent years the city was ravaged frequently by fire.

(R. W. LN.)

PORT BLAIR, the administrative centre and chief port of the Andaman and Nicobar Islands (*q.v.*), which together constitute a Union Territory of the Republic of India. It lies on the southeast shore of South Andaman in the Indian Ocean, latitude 11° 42' N, longitude 93° E. Pop. (1961) 14,075. The port is linked by sea with Calcutta, 810 mi. NNW, and Madras, 840 mi. WNW, and has an airfield with regular service to Calcutta. Occupied in 1789 by Capt. Archibald Blair, the site was named Port Cornwallis. It was abandoned after two years but was resettled in 1858 and named Port Blair. It possesses one of the finest harbours in Asia. From 1858 to 1945 there was a penal settlement on the islands and Port Blair was the headquarters. In World War II it was under Japanese occupation from 1942 to 1945. (L. D. S.)

PORT CHESTER, a village in Westchester county, N.Y., U.S., on Long Island sound at the mouth of the Byram river, which separates it from Connecticut.

Port Chester's earliest history began with Peter Disbrow's purchase of the southern part of its present site on Jan. 3, 1660, from the Siwanoy Indians, a Mohegan tribe. In 1661 he and his associates proclaimed Charles II their lawful monarch in defiance of the claims of the Dutch West India company (see LONG ISLAND: History). As early as 1732 the settlement was known as Saw

Pit because of the important shipbuilding trade that had developed there. On March 11, 1837, the name was changed to Port Chester, and the village was incorporated under that name on May 14, 1868.

Although Port Chester is a residential suburb, there were in the 1960s more than 600 business firms and manufacturing establishments making or selling such products as candy, cough drops, bread products, plastics, porcelainized products, nuts and bolts, women's hats and men's shirts.

For comparative population figures see table in NEW YORK: *Population*. (M. D. HH.)

PORTE, SUBLIME, the name once given to the Turkish government, is a European translation of the Turkish *Babiâli*, the High Gate or Gate of the Eminent. This was the official name of the gate giving access to the block of buildings in Istanbul which housed the principal state departments. Early in the history of the Ottoman Empire the grand viziers became powerful but it was only in the 17th century that they acquired the official residence, *Babiâli*, which became the real centre of government. There, too, were the offices of the foreign ministry and the council of state; hence the application of the term to the government as a whole. (A. D. A.)

PORT ELIZABETH, a seaport situated on Algoa Bay, 436 mi. (702 km.) by sea east of Cape Town in Cape Province, Republic of South Africa. The total population in 1960 was 245,985, of whom 84,505 were whites, 106,162 Bantu, 51,453 Coloured, and 3,865 Asian.

Port Elizabeth was settled after Fort Frederick was founded in 1799 and developed rapidly with the completion of the Kimberley Railroad (1873). It lies midway between Cape Town and Durban, and is the third port of South Africa. The area south of the harbour has become a seaside resort possessing some of the finest beaches in South Africa and extensive residential development. The main business centre of the town is situated immediately inland from the harbour, with further residential areas stretching about 12 mi. inland. To the north of the town more than 3,000 ac. of land have been developed with industries, the largest establishments being those of the automotive industry; and in the 1960s further industrial expansion over an area of more than 1,000 ac. was projected.

Like other South African ports, the port is owned by the government but administered by South African Railways. The harbour, with a water area of 314 ac., is enclosed and has three quays, one 3,540 ft. long and the others each 1,700 ft. long. The depth of the water in the harbour is 36 ft. above low-water ordinary spring tides and is capable of taking any ocean-going liner. The port handles a large proportion of the imports for Zambia and Southern Rhodesia by virtue of its excellent rail communication system with the hinterland. Ample cold storage facilities exist to handle the increased citrus exports. Ore-loading and discharging berths of 1,200 ft. take ships of up to 65,000 tons and there are storage facilities for 180,000 tons. This project cost R.5,500,000 and was undertaken after World War II when the industries of Port Elizabeth developed more rapidly than those of any other town in the republic. By the 1960s there were more than 500 factories engaged in more than 80 types of industrial activity.

PORTEOUS, JOHN (d. 1736), captain of the city guard of Edinburgh, whose name is associated with the riots of 1736, which provided the plot for Sir Walter Scott's novel *The Heart of Midlothian*, was the son of Stephen Porteous, an Edinburgh tailor. He served in the army in Flanders in the War of the Spanish Succession and upon the outbreak of the Jacobite Rebellion in Scotland in 1715 was appointed as drillmaster to the city guard of Edinburgh. By January 1726 he had risen to be one of the three captains lieutenant in the guard. On April 14, 1736, a smuggler, Andrew Wilson, who had won popular sympathy in Edinburgh by helping a friend to escape from prison, was hanged. A riot broke out at the execution and the city guard fired into the crowd. Porteous, who was accused of giving the order to fire, and of firing himself, was brought to trial in July and sentenced to death. After he had sent a petition for pardon to Queen Caroline, then acting as regent in the absence of George II, his execution was postponed.

On the night of Sept. 7, 1736, an armed mob broke into the Tolbooth prison in Edinburgh, seized Porteous, and hanged him from a signpost in the street. The government in London ordered an inquiry, but no one was ever convicted of the murder. In 1737 a harsh Pains and Penalties Bill was introduced, but in its final form was much modified. The city of Edinburgh was fined £2,000 and the lord provost was disqualified from holding any other office.

See W. Roughead (ed.), *Trial of Captain Porteous* (1909); P. H. Brown, *History of Scotland*, vol. iii (1911).

PORTER, COLE (1893–1964), U.S. composer of musical comedies and popular songs, was born in Peru, Ind., on June 9, 1893. He studied at the Harvard School of Music and during World War I served in the French Army. Among his successful musical comedies, combining sentimental appeal with sophisticated satire, were *Anything Goes* (1934), *Dubarry Was a Lady* (1939), *Panama Hattie* (1940), *Kiss Me, Kate* (after Shakespeare's *The Taming of the Shrew*) (1948), *Can-Can* (1953), and *Silk Stockings* (1955). His popular songs include *Begin the Beguine* and *Night and Day*. All his musical comedies and songs were written to his own words. He died in Santa Monica, Calif., on Oct. 15, 1964. (N. Sr.)

PORTER, DAVID (1780–1843), U.S. naval officer who commanded the frigate "Essex" on her famous expeditions during the War of 1812, was born in Boston, Mass., on Feb. 1, 1780. His father, David, commanded U.S. ships in the American Revolutionary War. In 1796 he accompanied his father to the West Indies; on a second and on a third voyage he was impressed on British vessels, but he escaped. He became a midshipman in the U.S. navy in April 1798; served on the "Constellation" and was midshipman of the foretop when the "Constellation" defeated the "Insurgente"; was promoted lieutenant in Oct. 1799 and was in four successful actions with French ships in that year.

In 1803, during the war with Tripoli, he was first lieutenant of the "Philadelphia" when that vessel grounded, he was taken prisoner and was not released until June 1805. He was commissioned master commandant in April 1806; from 1807 to 1810 he served about New Orleans, where he captured several French privateers, and in 1812 was promoted captain. He commanded the "Essex" in her famous voyage (1812–14). In the Atlantic he captured seven brigs, one ship, on Aug. 13, 1812, the sloop "Alert" the first British war vessel taken in the War of 1812. Without orders from his superiors he then (Feb. 1813) rounded Cape Horn and in the South Pacific captured many British whalers and took formal possession (Nov. 1813) of Nukuhiva, the largest of the Marquesas Islands. The United States, however, never asserted any claim to the island, and in 1842, with the other Marquesas it was annexed by France. During most of February and March 1814 he was blockaded by British frigates in the harbour of Valparaiso, and on March 28 was defeated. Released on parole, he sailed for New York.

He was a member of the new board of naval commissioners from 1815 until 1823, when he commanded a squadron sent to the West Indies to suppress piracy. One of his officers, who landed at Fajardo (or Foxardo), Puerto Rico, in pursuit of a pirate, was imprisoned by the Spanish authorities on the charge of piracy. Porter, without reporting the incident or awaiting instructions, forced the authorities to apologize. He was recalled (Dec. 1824), court-martialed and suspended for six months. In Aug. 1826 he resigned his commission, and until 1829 was commander in chief of the Mexican navy, then fighting Spain. President Andrew Jackson appointed him consul general to Algiers in 1830 and in 1831 created for him the post of chargé d'affaires at Constantinople, where in 1841 he became minister. He died in Peru on March 3, 1843.

He wrote a *Journal of a Cruise Made to the Pacific Ocean in the U.S. Frigate "Essex" in 1812–13–14* (1815; 2nd ed., 1822), and *Constantinople and Its Environs* (1835), which is a valuable guidebook.

See the *Memoir of Commodore David Porter* (1875), by his son Adm. David D. Porter.

PORTER, DAVID DIXON (1813–1891), U.S. naval officer who held important commands during the American Civil War.

was born in Chester, Pa., on June 8, 1813. His first voyage, with his father, Capt. David Porter, in West Indian waters (1823-24), was terminated by the Fajardo affair (see PORTER, DAVID). In April 1826 he entered the Mexican navy, of which his father was commander in chief, and which he left in 1828 after the capture by the Spanish of the "Guerrero," on which he was serving under his cousin, David H. Porter (1804-28), who was killed before the ship's surrender. He became a midshipman in the U.S. navy in 1829 and was in the coast survey (1836-42). Porter became a lieutenant in Feb. 1841 and served at the naval observatory from 1845 to 1846, when he was sent to the Dominican Republic to report on conditions there. During the Mexican War he served as lieutenant and then as commanding officer of the "Spitfire," a paddle vessel built for river use, and took part in the bombardment of Veracruz. In 1855 and in 1856 he made trips to the Mediterranean to bring to the U.S. camels for army use in the southwest. In April 1861 he was assigned to the "Powhatan," and was sent under secret orders from the president for the relief of Ft. Pickens, Pensacola. Porter was promoted commander on April 22, and on May 30 was sent to blockade the Southwest pass of the Mississippi. Upon his return to New York in November he urged an expedition against New Orleans (q.v.), and recommended the appointment of Comdr. D. G. Farragut (q.v.), his foster brother, to the chief command.

In the expedition Porter himself commanded the mortar flotilla, which, when Farragut's fleet passed the forts on the early morning of April 24, 1862, covered the passage by a terrific bombardment that neutralized the fire of Ft. Jackson. At Vicksburg Porter's bombardment assisted Farragut to run past the forts (June 28). On July 9 Porter was ordered, with ten mortar boats, to the James river, where McClellan's army was concentrated. On Oct. 15 he took command of the gun vessels and had a share in the capture of Arkansas Post (Jan. 11, 1863). In the operations for the capture of Vicksburg in 1863 unsuccessful attempts were made by Porter's vessels to penetrate through connecting streams and bayous to the Yazoo and reach the right rear of the Confederate defenses on the bluffs, but the fleet ran past the Vicksburg batteries, mastered the Confederate forts at Grand Gulf and made it possible for Grant's army to undertake the brilliant campaign which led to the fall of the place (see AMERICAN CIVIL WAR and VICKSBURG). Porter received the thanks of congress for "opening the Mississippi river" and was promoted rear admiral. He co-operated with Maj. Gen. N. P. Banks in the Red river expeditions in March-May 1864, in which his gunboats, held above Alexandria by shallow water and rapids, narrowly escaped isolation. On Oct. 12, 1864, he assumed command of the North Atlantic blockading squadron, then about to engage in a combined military and naval expedition against Ft. Fisher, N.C. Porter claimed that his guns silenced Ft. Fisher, but Maj. Gen. B. F. Butler, in command of the land forces, refused to assault, asserting that the fort was practically intact.

After Butler's removal, Porter, co-operating with Maj. Gen. Alfred H. Terry and commanding the largest fleet assembled at any one point during the war, took the fort on Jan. 15, 1865; for this he again received the thanks of congress. From 1865 to 1869 he was superintendent of the U.S. Naval academy, Annapolis, which he greatly improved, his most notable change being the introduction of athletics. On July 25 he became vice-admiral. From March 9 to June 25, 1869, while Adolph E. Borie (1809-80) of Pennsylvania was secretary of the navy in President Grant's cabinet, Porter was virtually in charge of the navy department. In 1870 he succeeded Farragut in the grade of admiral. He died in Washington, D.C., Feb. 13, 1891.

Porter wrote a *Life of Commodore David Porter* (1875), gossip *Incidents and Anecdotes of the Civil War* (1885), a none too accurate *History of the Navy During the War of the Rebellion* (1887), two novels, *Allan Dare* and *Robert le Diable* (1885; dramatized, 1887) and *Harry Marline* (1886), and a short "Romance of Gettysburg," published in *The Criterion* in 1903.

See J. R. Soley, *Admiral Porter* (1903).

Admiral Porter's three brothers were in the service of the United States: WILLIAM DAVID PORTER (1809-64) commanded

the "Essex" on the Tennessee and the Mississippi in the Civil War and became commodore in July 1862; THEODORIC HENRY PORTER (1817-46) was the first officer of the U.S. army killed in the Mexican War; and HENRY OGDEN PORTER (1823-72) resigned from the U.S. navy in 1847, after seven years' service, fought under William Walker in Central America, returned to the U.S. navy, was executive officer of the "Hatteras" when she was sunk by the "Alabama" and received wounds in the action from the effects of which he died several years later.

PORTER, ENDYMION (1587-1649), English courtier, the most trusted of Charles I's personal attendants, and a patron of art and literature, was born at Mickleton, Gloucestershire, in 1587. From 1605 to 1612 he was in Spain, where he had family connections, and on returning to England, entered Edward Villiers' service. In 1617 or 1618 he became master of horse to Edward's half brother, George, later duke of Buckingham, and in 1619 he married Buckingham's niece, Olivia Boteler. In 1621 he became personal attendant to Prince Charles. He took part in the secret negotiations for the Spanish marriage (1622) and accompanied Charles and Buckingham on their clandestine visit to Madrid (1623).

On Charles' accession (1625), Porter was made a groom of the bedchamber. He continued to be employed in diplomacy with Spain, but his main duties were concerned with the arts. He negotiated many of the purchases that made the royal collection one of the finest in Europe, and acquired a notable private collection of his own. He knew Rubens and was a friend of Van Dyck, who painted portraits of him. Sir William Davenant owed his rise to Porter, and addressed 13 poems to him and his family, and Herrick praised his learning, wit, and "sweet temper." He acquired considerable wealth in the 1630s, through royal gifts, fines, wardships, leases on crown lands, patents, monopolies, and commercial enterprises under royal license.

Porter sat in the Long Parliament for Droitwich, and in January 1642 left London with the king, to whom he remained a faithful servant during the Civil War. Of the 11 Royalists exempted from the pardon offered by Parliament in September 1642, he was the only one not in high office—a tribute to his confidential position, his Spanish connections, and his wife's Catholicism. After the Battle of Naseby (1645) he was sent to France with letters for the queen, and remained in exile, in Paris and Brussels, until the winter of 1648-49. In April 1649 he appeared at the Court of Compounding in London, and was permitted to compound for his delinquency by a fine. Exhausted by the hardships of the war years, he died in London in August 1649.

See G. Huxley, *Endymion Porter* (1959).

PORTER, HENRY (ß. 1589-1599), English dramatist, author of *The Two angrie women of Abington* (publ. 1599), may have matriculated at Brasenose College, Oxford, on June 19, 1589. Entries in Philip Henslowe's *Diary* between Dec. 16, 1596, and April 16, 1599, suggest that Porter was successful but needy. He collaborated with Henry Chettle and Ben Jonson on *Hot Anger Soon Cold* (1598) and with Chettle on *The Spencers* (1599); neither has survived. In 1598 Porter provided the Admiral's Men with a lost play, *Love Prevented*. In February 1599, they performed the second part of *The Two angrie women* and he contracted to write them *The Two merrie women of Abington*. Porter was wounded in a duel by John Day (possibly the dramatist) on June 6, 1599, and died the next day. He wrote lively, coherent prose and verse dialogue and had a talent for comic plot and character.

BIBLIOGRAPHY.—*The Two Angry Women of Abington*, ed. by C. M. Gayley in *Representative English Comedies* (1903), and by W. W. Greg for the Malone Society (1912). See also J. M. Nosworthy, "Henry Porter," in *English*, vol. vi, no. 32 (1946). (B. L. J.)

PORTER, KATHERINE ANNE (1890-), U.S. writer of fiction, whose best-known novel, *Ship of Fools*, appeared in 1962, was born May 15, 1890, at Indian Creek, Tex., and educated at Southern convent schools. For many years she lived abroad—in Mexico, where she did much to stimulate interest in Mexican art and culture, and in Paris and Berlin. These experiences as well as those of her girlhood in the South are reflected in her

stories. Though she wrote early and voluminously, she made no attempt to publish until about 1925. The appearance in 1930 of her first collection of stories, *Flowering Judas*, won her immediate critical acclaim. *Hacienda* followed in 1934 and in 1939 *Pale Horse, Pale Rider: Three Short Novels*. This volume established her as one of the foremost short-story writers of the period, but it was not until 1962 that *Ship of Fools* first brought her a truly wide circle of readers.

Critics have praised her for the extraordinary purity and concentration of her style, but her style never becomes a mere preciousness: it is made to serve her vision of life whether her theme is the individual's fight to maintain spiritual integrity or the vicissitudes of growing up or the attempt to discover the meaning of one's past. Other works by Miss Porter include *The Leaning Tower, and Other Stories* (1944) and *The Days Before* (essays and reviews) (1952).

See Edward Schwartz, *Katherine Anne Porter: a Critical Bibliography* (1953). (C. Bs.)

PORTER, WILLIAM SYDNEY: see HENRY, O.

PORTES GIL, EMILIO (1891–), Mexican provisional president (1928–30) and statesman, was born in Ciudad Victoria, Tamaulipas, on Oct. 3, 1891. After teaching for two years (1910–12) he entered law school and was in Mexico City when the revolution led by Venustiano Carranza began. After late 1914 Portes Gil served the revolution in various legal capacities in Mexico City, in Sonora, and in Tamaulipas. He supported Alvaro Obregón in 1920, and after Obregón's victory over Carranza in that year Portes Gil became provisional governor of Tamaulipas. He served parts of four terms in the National Congress, was governor of Tamaulipas (1925–28) and minister of government (1928) prior to his election by Congress to the provisional presidency, in which he served from Dec. 1, 1928, to Feb. 5, 1930. He then was elected president of the official political party (National Revolutionary Party), but dissension forced his resignation and he was sent to France as minister in 1931; while in Europe he also was delegate to the League of Nations. Returning in 1932 Portes Gil became attorney general, from which post he moved to minister of foreign relations in 1934. In 1936 he retired from political life, devoting his time to private affairs and to encouraging intellectual and artistic development in Mexico. (C. C. Cu.)

PORT GLASGOW, a large burgh of Renfrew, Scot., on the south bank of the Firth of Clyde, 19 mi. (31 km.) WNW of Glasgow by road. Area 1.8 sq.mi. Pop. (1961) 22,559. It is continuous with Greenock. The industries include large shipbuilding and engineering works and sawmills. The area of the docks, both wet and graving, is 16½ ac. The graving dock (1762) was the first dock of the kind in Scotland. The first Clyde steamship, the "Comet," was built at Port Glasgow in 1812. In 1775 it was made a burgh of barony. Nearby are the ruins of 16th-century Newark Castle.

PORT HARCOURT, the second port of Nigeria, Africa, lies about 41 mi. (66 km.) from the sea on the Bonny river, an eastern tributary of the Niger, in an area of mangrove swamps and rain forest. The climate is hot and humid with an annual rainfall of 94 in., largely between April and November. The most congenial months are January and December. Pop. (1960 est.) 42,553. It covers about 12 sq.mi. between the Bonny river (W.), the Amadi (E.) and Nwatugbo (S.) creeks. First marked out in 1912 on a derelict site known as Obomotu, and linked by rail in 1916 with the Enugu coal fields, the port has continually expanded. The main streets are wide, with modern-style buildings and the principal commercial and residential houses are grouped around a central area known as The Circle, though there are new residential quarters to the northwest and southeast. The many open spaces include Jubilee Memorial Park and a sports stadium.

Port Harcourt is in the Eastern Region and is the terminus of the eastern branch of Nigerian railways; it is linked by road and internal air services with the rest of the federation. The airport is 7 mi. N.E. on the Aba road. Local industries include cement, cigarette and metal window frame and door manufacture. The port has deepwater berths and bulk palm oil storage plants, and its increasing traffic necessitated a further large expansion of the facilities in the late 1950s. Its exports, mainly palm oil and ker-

nels, cocoa, coal, tin and peanuts, were extended by mineral oil from the newly developed oil fields of the Niger delta.

(W. H. I.)

PORT HURON, a city of southeastern Michigan, U.S., 57 mi. (92 km.) NE of Detroit at the lower end of Lake Huron on the St. Clair River, opposite Sarnia, Ont., with which it is connected by a railway tunnel and the Bluewater International Bridge. It is a port on the St. Lawrence Seaway. Port Huron, the seat of St. Clair County and the centre of a thriving agricultural community, has many industries and is a popular summer resort. It has a commission-manager form of government and a public junior college, established in 1923. (For comparative population figures see table in MICHIGAN: Population.)

In 1686 Ft. St. Joseph was built within the present city limits by Daniel Greysolon, Sieur du Lhut (Dulhut), a French trader and explorer; the British took possession in 1761 and the Americans built a fort on the site in 1814, naming it Ft. Gratiot for Capt. Charles Gratiot, who supervised its construction. The settlement which had grown up around the fort was incorporated as the village of Fort Gratiot in 1840; in 1893 it joined the other communities along the St. Clair River which had formed the city of Port Huron in 1857. Thomas A. Edison (q.v.) lived there as a boy; a boulder in Pine Grove Park stands near the site of his home. (V. A.)

PORTICI, a seaside town of the province of Napoli (Naples) in the region of Campania, south Italy, is 5 mi. (8 km.) SE of Naples, with Mt. Vesuvius to its northeast and the buried Roman town of Herculaneum close by. Pop. (1961) 51,397 (commune). The chief buildings are the 18th-century church of S. Ciro with pictures by Luca Giordano, and the ornate Palazzo Reale, begun in 1738 by Charles of Bourbon (later Charles III of Spain), which houses mosaics, etc., from Herculaneum and the agriculture faculty of the University of Naples. Portici is on the Naples-Salerno railway and near the Naples-Castellammare motorway. Fishing is carried on and apples, pears, olives, nuts, and hemp are grown. Wine and fertilizers are made. The small port is fairly busy.

As a medieval fief, Portici was owned by various princely families; it later passed to the kingdom of Naples. The town was completely destroyed by the eruption of Vesuvius in 1631. Italy's first railway (Portici-Naples) was inaugurated there in 1839. (M. T. A. N.)

PORT JACKSON: see SYDNEY.

PORT KEMBLA, a town and port of New South Wales, Austr., lies 55 mi. S of Sydney and forms part of Greater Wollongong (see WOLLONGONG). Pop. (1961) 7,830. Since the establishment of iron and steel works in 1926, Port Kembla has developed into an important industrial centre, producing about 2,600,000 tons of steel ingots annually.

Other industries include the smelting and refining of copper and other metals, and the manufacture of tin plate, wires and cables, sulfuric acid, fertilizers, and metal products. There is also a large power station.

The artificial harbour has grown from a jetty built in 1883 to ship coal mined at Mount Kembla in the Illawarra Range to the west; after 1960 a new harbour was built to provide many more berths, with a depth of 32 ft. at low water. The chief imports are ironstone, limestone, and liquid fuels; iron and steel products and coal are the chief exports.

PORTLAND, HANS WILLEM BENTINCK, EARL OF (1649–1709), Anglo-Dutch statesman, was a close friend of Prince William III of Orange, afterward King William III of England, and for 30 years his *alter ego* in politics, diplomacy, and war. He was born on July 20, 1649, the fourth son of Bernhard Bentinck of Diepenheim, a member of the Gelderland nobility. He made his career at Prince William's court, where he was page of honour and, from 1672, gentleman of the bedchamber, and in the army, becoming colonel of horse guards in 1675. In 1677 he preceded William to England to make a formal request on his behalf for the hand in marriage of Princess Mary, daughter of James, duke of York (later James II). He returned on missions of compliment in 1683 after the failure of the Rye House plot and in 1685 after the duke of Monmouth's rebellion. On each occasion he was

entrusted with highly confidential negotiations, with Charles II to try to enlist his support against Louis XIV of France, and with James II to dissipate suspicions that William had favoured Monmouth. Bentinck corresponded with William's supporters in England in 1687 and 1688 and supervised the arrangements for William's expedition to England in 1688. As a reward for his services, in 1689 he was appointed to the privy council, made groom of the stole, and created earl of Portland.

Portland fought at the Boyne (1690), Landen (1693), and Namur (1695), and William used him extensively as an intermediary with his English ministers. He had an important share in the conclusion of the Treaty of Rijswijk (1697), was English ambassador to France (1698), and on William's behalf, but unknown to the English Parliament, he signed with Louis XIV the two treaties, of 1698 and 1699, for the partition of the Spanish Empire. When the treaties were made public in 1701, Portland was impeached (April), but the proceedings were discontinued in July when the danger of war with France became a more important issue. Like all William's Dutch advisers, Portland was unpopular in England; in 1695 the House of Commons prevented him from obtaining a large grant of crown land in Denbighshire, and the Act of Resumption in 1700 deprived him of the large estates in Ireland which he had received after the suppression of the rebellion in 1691. From 1697 his jealousy of William's favourite, Arnold Joost van Keppel, 1st earl of Albemarle, poisoned his relations with the king, and after provoking a series of quarrels with William, he resigned all his offices in 1700 and virtually retired from court. However, he was finally reconciled to the king on William's deathbed two years later. He was occasionally employed on public business under Queen Anne but was more often in Holland than in England. He died at Bulstrode, Buckinghamshire, on Nov. 23, 1709.

See M. E. Grew, *William Bentinck and William III* (1924); A. S. Turberville, *History of Welbeck Abbey and Its Owners*, vol. ii (1939). (J. P. K.)

PORTLAND, WILLIAM HENRY CAVENDISH BENTINCK, 3RD DUKE OF (1738–1809), English statesman, prime minister from April to December 1783 and from 1807 to 1809, was born on April 14, 1738, at Bulstrode, Buckinghamshire, the eldest son of William, 2nd duke of Portland. He was educated at Westminster and Christ Church, Oxford, and succeeded his father as 3rd duke in 1762. From July 1765 to December 1766 he was lord chamberlain of the household. In the marquess of Rockingham's second ministry he was appointed lord lieutenant of Ireland (April 1782), but resigned (August 1782) after the earl of Shelburne became prime minister. On Shelburne's fall, Portland was selected by Lord North and Charles James Fox as nominal head of their coalition ministry. He was dismissed in December 1783 when Fox's India Bill was, under the king's influence, thrown out by the House of Lords. Regarded as leader of the Rockingham Whigs, Portland lived in semiretirement until the progress of the French Revolution and the outbreak of war with France led him to support William Pitt's administration. He was secretary of state for the home department from July 1794 until July 1801, when he became lord president of the council. He relinquished that office in January 1805, but remained in the cabinet during the last year of Pitt's second ministry. On Pitt's death in January 1806 he retired, but was brought back as prime minister in March 1807. The dominating figures in his second ministry were Viscount Castlereagh and George Canning. Troubled by their disagreements and by persistent ill health, he resigned in September 1809. He died at Bulstrode on Oct. 30, 1809.

See A. S. Turberville, *A History of Welbeck Abbey and Its Owners*, vol. ii (1939). (A. AL.)

PORTLAND, the largest city in Maine, the seat of Cumberland County and a port of entry, is located on Casco Bay 110 mi. (177 km.) NE of Boston. The city is built largely on two hilly peninsulas which command arresting views of Casco Bay and its many islands. Pop. (1960) 72,566; Portland standard metropolitan statistical area (SMSA), comprised of the cities of Portland, South Portland, and Westbrook, and the towns of Falmouth and Cape Elizabeth, 120,655. The towns of Cumberland, Gorham,

Scarborough, and Yarmouth (1960 pop. 18,467) were added to the SMSA in 1963. (For comparative population figures see table in MAINE: Population.)

Portland was first settled in 1632 by the Englishmen Richard Tucker and George Cleeve. During its early years it was known by several names and suffered various disasters. It was destroyed in 1676 by Indians and in 1690 by French and Indians. In 1775 a British fleet bombarded the settlement as punishment for patriotic activities. It was rebuilt and then was incorporated as a town in 1786, when it took the name of Portland. When Maine became a state in 1820 Portland served as the capital until 1832. It also was incorporated as a city in 1832. A fire which resulted from an Independence Day celebration destroyed much of the centre of the city on July 4 and 5, 1866. Reconstruction soon took place, however, and the city continued to grow. Portland's traditional fishing, shipping, and commercial activities were increasingly supplemented by the development of manufacturing industries. The city was important in the building and operation of naval ships in both World Wars I and II. It has a council-manager form of government which it adopted in 1923.

Portland is the transportation and commercial centre of southwestern Maine. It has an excellent harbour, which is served by several steamship lines. It is a major petroleum port and is the eastern terminus of the Portland-Montreal oil pipeline. The metropolitan area has a diversified manufacturing base. Among the chief products are pulp and paper, a variety of canned and processed foods, textiles, lumber and wood products, furniture, footwear, chemicals, metal goods, and various types of machinery. There is also considerable shipbuilding, printing, and publishing in the area. Fishing is an important source of employment.

Educational facilities include a branch of the University of Maine and Westbrook, a private junior college for women. Two museums, an art gallery, and music and drama groups contribute to the area's cultural activities. (H. A. PE.)

PORTLAND, the largest city of Oregon, U.S., and the seat of Multnomah County, is in the northwestern part of the state. Its original site was a shallow bench of land between low but steep wooded hills and the west bank of the Willamette River, 10 mi. (16 km.) from its entrance into the Columbia River. This remains the financial and commercial centre of the city. Zoned residential, commercial, and industrial developments have spread out to occupy the plain on the east side of the Willamette, extending to the Columbia. From the city's heights, to the east, can be seen an encirclement of low foothills climaxed in the snow-capped summit of Mt. Hood, 48 mi. (75 km.) away, and in the farther distance, the peaks of Mt. St. Helens and Mt. Adams in Washington. To the west lie the Tualatin Valley, the Coast Range Mountains, and beyond, less than 100 mi. away, the Pacific Ocean. Pop. (1960) city 372,676; standard metropolitan statistical area (Multnomah, Washington, and Clackamas counties, Oregon; Clark County, Washington) 821,897. (For comparative population figures see table in OREGON: Population.)

History.—Portland was founded in 1845 and was named for the city in Maine. Deep water for oceangoing vessels and the opening of a road to the wheat producing farms of the Tualatin Valley in the early 1850s gave it commercial advantages over rival town sites. By 1860, when its population was less than 3,000, it was the largest town in the Pacific northwest and remained so until outstripped by Seattle at the turn of the century. Between 1850 and 1870 Portland was the outfitting point and supply centre for northwest gold rushes and interior settlement. Thrifty and conservative businessmen, many originally from New England, invested capital earned during these prosperous times in real estate and transportation facilities. Locally owned stern-wheelers navigated the rivers and carried agricultural traffic to Portland; after 1880 it became one of the nation's chief grain exporting ports. In the 1860s and 1870s Portland's residents invested heavily in railroad lines to California and in the Northern Pacific Railway Company which gave them their first transcontinental connection in 1883. By 1910 all major western steam railroad lines entered Portland.

In 1889 a local company brought electric power to Portland

from Oregon City, 14 mi. up the Willamette, over the world's first long-distance transmission line. With the completion of Bonneville Dam on the Columbia in 1940 the availability of hydro-electric power began to attract metallurgical and chemical industries to the metropolitan area.

Local residents early advertised Portland as the city of homes as well as "the city of roses," celebrated in an annual rose festival. Multiple-unit dwellings were slow to develop until the mid-20th century, when long-range urban renewal projects, a new airport, and the building of an express highway also began to change the appearance of the city.

Government.—Portland is governed by an elected, nonpartisan board of five commissioners and a mayor. It operates only minimum public utilities. A port commission with taxing powers and a public dock commission supervise harbour facilities.

Education and Cultural Activities.—Institutions of higher education in the city include Cascade, a private interdenominational college chartered in 1918 as the North Pacific Evangelistic Institute; Lewis and Clark, a Presbyterian college founded in 1867; Reed, a private nonsectarian college founded in 1904; the University of Portland, a Roman Catholic coeducational institution established in 1901; Multnomah opened in 1897 and organized as a junior college in 1931; and the medical and dental schools of the University of Oregon. Portland State College (which grew out of Vanport Extension Centre, established in 1946) became a degree-granting college in the Oregon state system of higher education in 1955. Wealthy and influential patronage supported such cultural institutions as a library, art museum and school, historical society, and symphony by the turn of the 20th century. In 1925 one of the first junior symphonies in the nation was founded in Portland. The Multnomah County Library, with headquarters in Portland, operates a number of branches and several bookmobiles.

The city school district, a separate taxing agency, operates elementary and high schools and a radio station and provides special programs for exceptional children.

Parks and Recreation.—Portland has over 100 park and recreational areas, including rose and zoological gardens, totaling over 6,000 ac. Forest Park, 3,500 ac., is a primitive area within the city limits. (D. O. J.)

PORTLAND, ISLE OF, a craggy peninsula on the coast of Dorset, Eng., is connected to the mainland by the Chesil bank, or beach, an unbroken ridge of shingle about 30 ft. high and 200 yd. wide, stretching 17 mi. W as far as Bridport. Pop. of urban district (1961) 11,569. Four miles long and nearly 1½ mi. wide in extreme breadth, it has an area of 4.5 sq.mi. and its precipitous shores render the island virtually inaccessible from the sea except toward the south. Its highest point is Verne Hill (490 ft.) in the north, and the southern tip is Portland Bill with its storm-worn caves, a raised beach, and the Pulpit Rock. The dangerous Portland race, where the tides meet, flows toward the Shambles sands 4½ mi. to the east and is marked by the Shambles lightship.

The substratum of the island is Kimmeridge clay overlain by beds of sand and strata of oölitic limestone—the famous Portland stone used extensively in the London architectural masterpieces of Sir Christopher Wren and many other well-known buildings. Because of a similarity in colour, the stone gave its name to Portland cement (*see* CEMENT). In the dirt bed on the oölitic strata are numerous specimens of petrified wood, some of great size.

The island is a royal manor whose court leet still functions. On it are the famous convict prison, converted in 1921 to a borstal institution, and the Verne Prison, formerly a barracks. Portland Castle, built by Henry VIII in 1520, is open to the public. The remains of the Norman Bow and Arrow Fortress (Rufus Castle) stand on the eastern cliffs in the grounds of Pennsylvania Castle which was built about 1800 by James Wyatt for John Penn, governor of the island and grandson of William Penn, founder of the state of Pennsylvania. Avic's cottage, facing the castle, is a local museum. The peninsula has been described by Thomas Hardy as the "Gibraltar of Wessex" and "The Isle of Slingers."

Portland's breakwaters, constructed by convict labour, enclose the great roadstead of Portland Harbour which was started by the

Admiralty in 1847–62. A breakwater stretching northward from the northeastern corner of the island partially enclosed a large area of water naturally sheltered on the south and west. An inner arm ran nearly east from the island to a masonry head and fort, and an outer detached arm bent north to a circular fort, a narrow entrance for shipping being left between the two. Two new breakwaters, built after 1895, closed the gap between the end of the outer breakwater and the Bincleaves rocks near Weymouth. The completely enclosed harbour covers 2,233 ac. to the one-fathom line, of which 1,500 ac. have a depth of not less than 30 ft. at low water.

After World War II a further naval establishment was built toward Portland Bill. There is a well-known local breed of small black-face sheep. Round the coast lobsters and crabs are caught.

(C. P. BN.)

PORTLAND CEMENT: *see* CEMENT.

PORTLAOISE (MARYBOROUGH), the county town of Leix (Laoighis), Republic of Ireland, lies on the Triogue River, 52 mi. (84 km.) SW of Dublin. Pop. (1961) 3,133. A sand and gravel esker runs northward from the town to Mountmellick and thence to Tullamore. Portlaoise, established as Fort Protector during the reign of Mary I (hence its common English name), was granted its charter in 1570, and a bastion of the castle still remains. The main industries are flour milling and the manufacture of worsted goods. On the Rock of Dunamase (the Fort of Masg), 3 mi. E, are the ruins of an old castle, the former seat of the kings of Leinster (*q.v.*). It was destroyed in 1650 by Oliver Cromwell's army.

PORT LOUIS, the capital and port of Mauritius (*q.v.*), is built round a small, well-sheltered harbour on the northwestern coast, and backed by an almost semicircular ridge of mountains which form part of an extensive range stretching toward the centre of the island. Because of these protective mountains, the town and harbour are almost entirely cut off from the normal east and southeast trade winds, and this makes Port Louis one of the hottest places in Mauritius in summer. The town covers an area of 2.1 sq.mi. (5.4 sq.km.). Pop. (1962) 89,096.

Port Louis was founded in about 1736 by the French governor Mahé de La Bourdonnais, and considerably improved in 1770. In appearance it seems a curious and fascinating assemblage of ancient and modern, Oriental and European, shabby and luxurious. Its streets are laid out in a rectangular network and it is dominated by an old fortress, the Citadel (1838), built on a hill almost in its centre. Port Louis possesses two cathedrals, St. Louis (Roman Catholic) and St. James (Anglican), and two fine Roman Catholic churches, a stately town hall, a natural history museum and art gallery, two public libraries, a theatre, a large public hospital, and several colleges. A small racecourse lies on the southeastern extremity and a public park on the northeastern seaboard. The Grand River North West, which runs on the outskirts, furnishes part of the freshwater supply.

The port, which is the main harbour on the island, has one deep-sea quay. From the Central Railway Station and clearing yard lines branch off to all parts of the island. Port Louis contains no large industrial establishment. Its industrial activity, besides that connected with docks and warehousing, is restricted to minor mechanical workshops, small food and wine manufactures, oil extraction and refining, sawmilling, printing, etc. On the outskirts of the town proper, however, are a big tobacco warehouse, a modern cigarette factory, a thermal power station, and a railway workshop. As the central collecting and clearing ground for all merchandise imported or exported from the island, the commercial activity of Port Louis is extensive in wholesale and retail sales. The main export is sugar (98% of domestic exports in value). (M. V. M. H.)

PORTO: *see* OPORTO.

PORTO ALEGRE, a city and port in southern Brazil, the capital of the state of Rio Grande do Sul. Pop. (1960) 617,629. It is located 670 mi. S.W. of Rio de Janeiro and 150 mi. N.N.E. of the seaport of Rio Grande at the entrance to the lake. Porto Alegre is at the northern end of the Lagoa dos Patos on an arm of the lake known as the Rio Guaíba. Into this end of the lake

five short but deep rivers empty their waters: the Gravataí, Sinos, Caí, Jacuí and its tributary the Taquari. Since the lower courses of these rivers are all navigable, Pôrto Alegre has become the most important centre of inland navigation in all of Brazil. The outlet of the Lagoa dos Patos, near Rio Grande, is too shallow to accommodate ships of more than 16½-ft. draft. The lake and rivers, however, provide a fine system of inland waterways to serve the chief area of concentrated settlement in the state. The city is built on a ridge of high ground on the edge of the lake. It is located about 30° south of the equator and its climate is one of mild winters and hot summers, with abundant rainfall (average of 50 in.). In winter cold waves from the south bring occasional frosts.

In addition to its function as administrative centre of the state Pôrto Alegre is also the chief commercial centre serving the whole of this southernmost part of Brazil. From the rural hinterland come a variety of agricultural and pastoral products: meat and hides, wool, rice, tobacco, grapes, cereals, manioc meal and maize. From the forests lumber is produced. In the city are many business and financial establishments serving this economically active region. Educational institutions include two universities, a medical school, a normal school and a school of agronomy and veterinary medicine. The city also ranks high among the industrial centres of Brazil. Manufacturing industries are chiefly those engaged in processing the products of the farms, forests and ranches; they include meat packing, lard refining, leather tanning, the weaving of woolen yarn and cloth and the manufacture of clothing, the brewing of beer and the manufacture of cigarettes, furniture, soap, candles, macaroni, farinha (manioc flour) and a variety of preserves and wines. There are also metal factories producing stoves, furnaces and iron safes and a shipbuilding and ship repair works. The city is provided with electric power by a large steam-electric plant making use of coal from the nearby mines at São Jerônimo, brought to Pôrto Alegre by river barge. Although this coal has a high ash content and requires the use of especially designed grates, it is cheaper than imported coal.

The city is connected by rail with the Uruguayan railroads at Sant'Anna do Livramento and with the Argentine railroads at Uru-guaiana. From the junction of Santa Maria, a rail connection exists all the way to São Paulo and Rio de Janeiro. Modern all-weather highways also connect Pôrto Alegre with the rest of Brazil and with neighbouring countries. Regular air connections tie the city to these same countries and regions.

Pôrto Alegre was founded in 1742-43 by immigrants from the Azores and was first known as Pôrto dos Cazaes. In 1825 the first German immigrants were settled in the country north and northwest of the city; later Italian settlers also came into this region. The administrative centre of Rio Grande do Sul was moved from Rio Grande to Pôrto Alegre in 1773; it was officially named capital of Rio Grande do Sul in 1807. (P. E. J.)

PORTO BELLO (PUERTO BELLO), a village on the Caribbean, 18 mi. N.E. of Colón, Panamá. Columbus named its site "beautiful harbour" in 1502; the city was founded March 20, 1597, by Francisco de Valverde y Mercado. As a point of trans-shipment and exchange for the colonial merchandise of Spain and South America it was famous for its annual fairs and notorious for its high prices, congested quarters and tropical fevers. Once the busiest city in the new world and target of concentrated wealth, it was attacked by the English buccaniers Sir Francis Drake (who was buried in Porto Bello bay), William Parker, Sir Henry Morgan and Edward Vernon. In 1713 Spain opened it to the trade of one British ship annually. The abandonment by Spain in the 18th century of the fleet system and fairs, the building of the Panama railroad in the 1850s and the opening of the Panama canal brought about its eclipse. It has ruins of great historic interest. Pop. (1960) 591. (A. R. W.)

PORTOFINO, a picturesque fishing village on the Riviera di Levante in Genova province, Liguria, Italy, 20 mi. (32 km.) S.E. of Genoa by road. Pop. (1961) 1,096 (commune). It stands on the small peninsula of Portofino whose evergreen-clad hills descend steeply to the Rapallo gulf. Brightly colour-washed houses line both sides of a deep inlet at the head of which is a small port where

yachts and sailing boats cluster. To the north (1½ mi.) is the monastery of La Cervara. Pope Gregory XI rested there on his way from Avignon back to Rome (1377) and Francis I of France was imprisoned there (1525) after the battle of Pavia. Southeast is the church of S. Giorgio, said to contain the relics of St. George brought by the crusaders from the Holy Land. Portofino has much tourist traffic. Pillow lace is made to traditional 18th-century patterns. (M. T. A. N.)

PORT-OF-SPAIN, the capital city and chief port of Trinidad and Tobago in the West Indies, lies on the west coast of Trinidad, below the northern peninsula, on the Gulf of Paria, which separates the island from the northeastern coast of Venezuela. Pop. (1960) 93,954.

On the hills behind Port-of-Spain are residential suburbs, such as Goodwood Park, and the city itself is well laid out with parks and squares. Woodford Square is the principal one, situated in the business district near Holy Trinity Cathedral. Queen's Park Savannah is at the centre of the city and from it radiate many of the most important streets, including Frederick Street, the main shopping thoroughfare, Charlotte Street, with its markets and small shops, and Cipriani Boulevard, Marli Street, and St. Clair Avenue, which are residential. Around Queen's Park Savannah are several buildings of historical and architectural interest: the former Government House which stands in the grounds (63 ac. [25 ha.]) of the Royal Botanical Gardens; Whitehall, which houses the office of the prime minister of Trinidad and Tobago; the palace of the Roman Catholic archbishop of Port-of-Spain; Knowsley House, which accommodates some government ministries; All Saints Church; and the Red House near Woodford Square, which houses the supreme court and government offices. Among educational institutions are Queen's Royal College (which is also used for evening classes of the government polytechnic institute), Fatima College, and St. Mary's College. The college of engineering and tropical agriculture of the University of the West Indies is situated at St. Augustine, 8 mi. (13 km.) E of the city.

Port-of-Spain is a commercial and retail centre and has in its vicinity a variety of industries, including the production of rum, bitters, beer, margarine and oils, cigarettes, plastics, and building materials. There are also sawmills, textile mills, and citrus canneries; and the tourist industry has increased. A hotel and catering institute and several technical institutes train workers for various industries, and government policy aims to attract new factories to the town.

Port-of-Spain is linked by good roads with other parts of Trinidad. It is the island's centre of broadcasting and publishes the main newspapers. The port has a key position on world shipping routes and is a centre of trade within the West Indies. The sheltered harbour accommodates medium-sized ships at eight berths, and there are smaller wharves and jetties. The main imports are food, timber, cotton, fertilizers, and manufactured goods; principal exports include crude petroleum and gasoline products, sugar, citrus fruit and juice, asphalt, cocoa, and coffee. The airport at Piarco, 16 mi. (26 km.) E of the city, is the chief airport of the Caribbean and is used by many of the world's principal airlines. (H. E. Cn.; O. C. Ma.)

PORTOLÁ, GASPÁR DE (c. 1723-c. 1784), commander of the expedition sent from New Spain to colonize Upper California, was born about 1723 in Balaguer, Catalonia. At the age of 11, according to his military record, he became an ensign in the dragoon regiment of Villaricosa. He was promoted to lieutenant of dragoons and grenadiers in the Numancia regiment, where he served 21 years, and later was made captain of the España regiment and took part in the campaign against Portugal.

After José Gálvez was sent to New Spain in 1765 as *visitador*, he became aware of British and Russian interest in the Pacific coast of North America, an area which Juan Rodríguez Cabrillo in 1542 and Sebastián Vizcaíno and Bruno Heçeta later had visited and partially charted in behalf of Spain. He secured the appointment of Portolá, then of noble rank and unmarried, as governor of the Californias. Portolá took office in October 1767 and, after organizing an expedition, sailed from San Blas and landed at La Paz, Lower California, on July 6, 1768. His first duty there

was to remove the Jesuits from their missions and replace them with Franciscans.

For the colonization of Upper California he prepared both land and sea expeditions with the intention that they were to rendezvous at San Diego and later advance to Monterey, a harbour which had been reported in 1603 by Vizcaino. Portolá led the land force, taking with him Fathers Junípero Serra, Juan Crespi, and several other priests to establish missions. He arrived at San Diego on July 1, 1769, after an arduous journey of four months from Loreto. On July 14 Portolá began the trip to Monterey but, failing to recognize the bay, he passed on to San Francisco Bay. There, realizing that the party had gone too far, he turned back on Nov. 11 and arrived in San Diego on Jan. 24, 1770. Within a few months he tried again and was successful in reaching and identifying Monterey, where a settlement was made. Portolá returned by sea to Mexico, surrendering his governorship in September 1770.

He became governor of the city of Puebla on Feb. 23, 1777. In 1784 the viceroy of New Spain reported that he had advanced Portolá 12 salary payments to enable him to return to Spain, but whether or not he ever attempted to make the journey remains unknown.

PORTO MAURIZIO: see IMPERIA.

PORTO-NOVO, capital of the Republic of Dahomey, West Africa, is built above the coastal lagoon on the edge of a plateau. Pop. (1965 est.) 69,500. The town was probably founded in the late 16th century, as the centre of a kingdom, by the merging of two villages, Aklon and Djassin. Portuguese sailors and traders were the first to establish themselves there and the slave trade flourished. The French did not settle there until the 19th century. A protectorate treaty was signed in 1863 by King Dé Sodji in order to oppose the English. The existence of this small, independent kingdom, protected by the French, was at the root of their conflict with Béhanzin, sovereign of the well-developed kingdom of Abomey; the struggle lasted until 1894, when Béhanzin surrendered to the French.

Porto-Novo has retained a distinctive appearance from its early European occupation. There are still numerous buildings in the colonial or Portuguese style, with balconies of carved wood, and some old African palaces, more or less in ruins. The European quarter is cramped but pleasant, with its long avenues planted with flame trees (*Delonix regia*) and flanked by modern buildings. The centre of the African town is animated, with its guilds of artisans, potters, dyers, tanners, and smiths. On the shore of the lagoon are an old-established fishermen's quarter and stone quarries. The old urban populations live on the east side; to the north and west the people are farmers. Porto-Novo, although the administrative centre, is a town of the past; Cotonou is the commercial and industrial metropolis of Dahomey. (J. D.)

PORTO-RICHE, GEORGES DE (1849-1930), French dramatist celebrated as the author of *Amoureuse* (1891), the best of a collection of four plays called *Théâtre de l'Amour*, was born at Bordeaux on May 20, 1849. His theme is sensual love, which he studies mainly in the maladjusted married couple, even in his war play *Le Marchand d'estampes* (1917). The theme is broadened in *Le Vieil Homme* (1911), in which the husband and wife are also a father and mother. "The father of few plays but the grandfather of many," as he said himself, he possessed originality, which had a far-reaching influence on his contemporaries. His first and last plays, *Un Drame sous Philippe II* (1875) and *Les Vrais Dieux* (1929), are historical dramas. In 1923 he was elected to the Académie Française. He died in Paris on Sept. 5, 1930.

PORT PHILLIP: see MELBOURNE.

PORT PIRIE, a city and seaport of South Australia on the eastern shore and toward the northern end of Spencer Gulf, 136 mi.

(219 km.) NNW of Adelaide by rail. Pop. (1961) 14,003. It is the natural port for the export of ore from Broken Hill (about 220 mi. NE). Most of this ore is smelted at Port Pirie and the main product is lead. The city's main exports are lead, ores, and wheat. It has a 24-cell wheat silo with a capacity of 2,200,000 bu. and an output rate of 400 tons per hour. In the mid-1960s Port Pirie was considered the second port of South Australia. It also has metallurgical and light industries. Port Pirie was made a rural city in 1953. (J. H. S. L.E.)

PORTRAIT PAINTING. A portrait is a record of certain aspects of a particular human being as seen by another. The sitter may be deified or merely flattered by the painter, satirized or even maligned but, as long as some sense of his individuality remains, a painting of him will be a portrait. The artist may be interested only in the sitter's physical appearance, his social position, his soul or his unconscious problems, but again, as long as the sitter's identity remains, the artist will have painted his portrait. Finally the painter may paint him with a concern for precision of detail or with apparent abandon, with an interest in photographic realism or with a composition of cubes; but still, whatever the style is, as long as the artist can suggest some aspect of a particular person, the work will be a portrait. (It may not be a very good portrait but that is another problem.)

The Portrait and History.—By its very nature the portrait grows out of a respect for the differences between human beings; therefore it is only in periods primarily interested in individual differences that portrait painting thrives. In classical Greece, where the ideal mattered more than human particularities, portraiture had no place. In the middle ages, when man should ideally have lost his identity in the contemplation of God, again portraiture had an insignificant role. In the 20th century, portrait painting, with certain exceptions, has not been an important art form, perhaps because photography has provided an inexpensive substitute or perhaps because the norm is worshiped more than specific human characteristics.

The reasons for a concern with the individual and a subsequent desire for portraits vary according to the period. The wish to have a portrait may be for religious reasons; e.g., the ancient Egyptians needed a durable portrait in stone enough like the body of the dead person with which it was buried to suggest his authority and thus deceive his Ka so it would reside in the image and not haunt the survivors. At other times the moving force may have been a conviction of the importance of the individual to the family's prestige, as it was for the noble Romans or for the great of Georgian England. The cult of the hero, whether knight or courtier, grew up in the late middle ages and was developed in the Renaissance; his individual virtues had to be recorded. In contrast to this, the 19th and 20th centuries have observed the human being realistically, almost critically; portrait painters (as well as novelists) have emphasized his physical peculiarities and his psychological problems. Circumstances such as these have helped determine the character of the portrait historically.

The Painter and the Sitter.—In a portrait the personality of the sitter is obviously of primary importance. It may not be equally apparent that the personality of the painter is just as significant, and that the character of the relationship between them is perhaps most relevant of all. When a fashionable patron commissions a portrait from a fashionable painter the relationship between painter and sitter may be a formal one, and the work will reflect that formality. When an artist instead chooses to paint a portrait from his own affection or interest the relationship between the painter and the sitter becomes intimate and revealing. A portrait may reveal the shyness, the apprehension, the arrogance, the amusement or the casualness with which the sitter regarded the artist.

The great moments in the history of portraiture are probably those when the personality of the artist can most completely comprehend his sitter's—when a Hans Holbein is capable of identifying himself with the merchant Gisze or a Diego Velázquez can meet the challenge of the realism of an Innocent X or a Jean Ingres can love the vulgarity of a Mme Moitessier. Out of such a rapport the greatest portraits are painted.

HISTORY

The beginning of the Renaissance, about 1400, introduced the first consistent tradition of portrait painting in the west. The Egyptians and the Romans who, unlike the Greeks, were portraitists, preferred sculpture. During the middle ages interest in the individual's mortal life had a lesser place; it was only toward the end of this period that a donor felt a need to have his individual piety recorded—not just by a symbol, his coat of arms perhaps, used to decorate some object he had given—but by having his own features reproduced as he knelt in devotion before the Virgin Mary.

The Sitter's Piety.—In the late middle ages Richard II (1367–1400) of England was painted kneeling, under the protection of his three patron saints, before a Madonna and Child surrounded by a circle of angels who look and point toward the suppliant king. There is some question whether this work, the "Wilton Diptych," was painted during Richard's lifetime or was commissioned by some admirer after his death. Whatever the circumstances were, the artist was not interested in visual probability; rather he imposed upon the scene the traditional conception of religious decorum by making the Virgin Mary appropriately larger than the three patron saints, who are bigger than the king, and by isolating Richard and the three saints in the left of the two panels which form the diptych.

The artist imposed the same medieval conventions in the portrait of Richard that he did in the arrangement of the whole. Richard's kneeling body has no apparent existence under the heavy robes which enclose it. All that is exposed are the head and the hands. The hands are held apart in a rather uncertain suppliant gesture before the Madonna to emphasize the humility of the king. That he is king is indicated by his crown and his gold brocaded robes, that he is Richard by the white hart with which his robe is decorated and which also hangs as an emblem around his neck. Finally, instead of using the three-quarter view of the face as he did for most of the other figures, the artist chose the position in which a person's features are most easily remembered—the profile. Richard's face is smooth, bland and young, its features delicate and somewhat pointed, his expression content. As long as he was identifiable, perhaps as much by the heraldic symbols as by his features, the purpose of the painting was served. The artist had clearly achieved the suggestion of the piety of this particular king.

RENAISSANCE

The Sitter Seen.—The convention of including the portrait of a donor in a religious work continued into the 17th century, but early in the 15th century during the Renaissance in both Italy and northern Europe independent portraits became common as an expression of the renewed interest of the Renaissance in the individual human being. One of the greatest portrait painters of the time was the Flemish artist Jan van Eyck (1385?–1441), and his most remarkable portrait was of an Italian merchant, Giovanni (or Jan) Arnolfini, and his wife. This painting has been shown to be more than a double portrait; it is a witness to the marriage of the Arnolfinis, which Van Eyck shows taking place, and is full of late medieval symbolism referring to the event: the single candle in the candelabra burning in daylight represents the unity of marriage; the fruit, so casually placed on the chest by the window sill, suggests the state of man before the fall; the dog represents domestic bliss; etc. The painting is more important as a portrait, however, because it is a rare attempt in the 15th century to paint a full standing figure and because both these figures are placed in their own familiar setting, no matter how fraught with symbolism it may be.

Although the garments the Arnolfinis wear are full they do not conceal their figures entirely; so Jan van Eyck, more than the artist of the "Wilton Diptych," makes use of their bodies to enrich his interpretation. The Italian merchant has narrow, sloping shoulders, he stands with his legs apart and his feet outspread; there is no suggestion of classical beauty or power. His body is, still in medieval terms, unimportant. He holds himself erect like an ascetic, somewhat aloof from his wife at whom he does not look,

his head and his lifted right hand concentrating upon the troth he is pledging. His wife is a gentler figure; her shoulders are bent, her head is modestly lowered in her husband's direction. Although Jan van Eyck proved here that full figures could be used meaningfully in a portrait, it was another hundred years before the practice became common.

The Arnolfini portrait is also remarkable in its effort to make the figures seem very natural in their environment. Their slippers, the wooden planks of the floor, the bed, the opened window with the warm sunshine streaming through it, the obvious details of a prosperous 15th-century home can be seen. Although the Arnolfinis are quite large for the scale of the room, the slippers and the dog in front of them seem to place them convincingly back into it. This position, combined with the visual interest demonstrated in the textures, in the quality of light and shadow and even in the reflection of the mirror (all of which the new technique of oil painting made more possible) makes this work a step toward a greater naturalism, a desire to give the illusion of the Arnolfinis as they might actually be seen in their own drawing room. This interest in the thing seen is apparent in Van Eyck's choice of the three-quarter view of the heads, which also brings the two sitters, particularly Jan, into a closer relationship with the spectators.

This portrait is in some respects essentially a tour de force which had no imitators; however, it displays a visual realism, characteristic of all Jan van Eyck's work, which became an integral part of northern Renaissance painting, particularly in the work of such gifted followers of Van Eyck as Rogier van der Weyden (c. 1400–64), Petrus Christus (c. 1420–72/73) and Hans Memling (c. 1430–94).

The Sitter of Authority.—In Italy in the 15th century portraiture took a somewhat different form. Federigo da Montefeltro, duke of Urbino (1422–82), might have the Umbrian painter, Piero della Francesca (c. 1420–92), paint him kneeling piously before the Madonna and Child but he also felt quite free to have himself painted as the symbol of authority over the world he ruled, without any of the implicit humility which Van Eyck's work still possessed. Like the painter of the "Wilton Diptych," Piero imposed relationships upon the work which are rational rather than visual. However, the basis for his reasoning was quite unlike the medieval painter's. The duke of Urbino is exaggeratedly and imposingly large in relation to the countryside, his own territory, behind him; Piero has made it quite clear that his sitter was master over nature rather than, like Richard, small and humble before God. In describing the silhouette of the duke's head and shoulders Piero used firm, clear contours which grow even more abrupt in the face—quite unlike the delicate, continuous lines which describe the figure of Richard. Their very severity suggests the harshness of the duke whose portrait is being painted to record his power rather than his piety. At the back of this small panel painting there is another study of the duke as part of a classically inspired triumphal procession; this makes the motivation for the portrait quite clear since, crowning the duke of Urbino, is the allegorical figure of Fame.

This portrait is a profile portrait. Since the duke had lost his right eye in the same tournament which had given his nose its distinctive shape, a profile portrait was probably mandatory. However, it was the position most characteristically chosen for Italian 15th-century portraits. One reason it was so popular may have been the authority of classical medals and gems. It is also possible that these artists may have felt, like the painter of the "Wilton Diptych," that the profile could most clearly characterize the distinctive features of a sitter's face. The profile places the emphasis upon the head as we know it or remember it to be rather than upon the visual impression which interested Jan van Eyck. Consistently the head is built up of separate facts, like the features revealed in the profile or in each curling strand of hair, rather than upon the visual unity of the whole; the imperfections of the moles and wrinkles, for example, do not destroy the alabaster smoothness of the skin.

Although the duke possessed the supreme kind of self-confidence which did not demand that a painter flatter him, indeed permitted

Piero to enumerate any facts with brutal honesty, the ultimate purpose was not a record of his appearance—but rather of his authority. And it is generally true of 15th-century Italian portraiture that, although the painter recorded the anatomical features of his sitters as he knew them to be, he was primarily concerned with the ideal to which these sitters aspired. Therefore as Piero in painting the duke suggested his worldly power, Domenico Ghirlandajo (1449–94) in painting Giovanna Tornabuoni degli Albizzi would emphasize her female dignity or Gentile Bellini (c. 1429–1507) in painting a doge would show his keen intelligence—qualities represented in their most perfect form.

The Sitter Idealized.—“*Mona Lisa*.”—In Florence, at the turn of the 16th century, painters and sculptors were not so interested in Piero's unequivocal realism of detail. An artist as renowned as Leonardo da Vinci (1452–1519) was seldom willing to paint a portrait and, when he did, it seems to have been because his sitter could be made to represent an ideal rather than a particular human being. The most famous portrait painting by his hand is of the wife of Francesco del Giocondo, the “*Mona Lisa*.” (For an illustration of this painting, see *LEONARDO DA VINCI*.) This work, from 1504, not only makes it clear that Leonardo was interested in idealization but also that he was perhaps sufficiently tempted by the technique of oil painting to want to achieve the illusionary effects for which Jan van Eyck had also strived.

More even than Van Eyck, Leonardo, in his portrait, makes the transitions so subtle that the illusion of a body of flesh and blood occupying space is almost complete; however, in spite of the fact that she seems so physically convincing, the “*Mona Lisa*” remains aloof. Her dress is simple but the bearing of her head, the position of her hands and the triangular form she occupies make her seem imposing and regal. The face which, more than mere flesh and blood, seems to radiate with an inner warmth is so provocative, so eternally enigmatic in its expression that it has tantalized the millions who have seen it in the Louvre or in reproduction. The landscape behind her increases the mystery; it is so much sheer fantasy that it seems related to the world of imagination rather than fact. The “*Mona Lisa*” is so generalized that it is perhaps not even a portrait; rather she is characteristic of the short-lived High Renaissance desire to concentrate upon the ideal rather than the particular.

The ideal which the “*Mona Lisa*” represents, no matter how illusive it is, is certainly a matter of inner life rather than physical externals; it radiates through her flesh and skin. The best portraits by Raphael (1483–1520) have somewhat the same quality. However, the inner spirit within a Raphael is neither so enigmatic nor so timeless; e.g., in the portrait of Julius II (1445–1513) in the Uffizi the inner spirit can show the effects of age and care. Raphael's ideal, at least in this portrait, was of a dignified and noble maturity. The weary shoulders, the head weighed forward, the white beard, the shadows under the eyes, the wrinkles enhance that effect. And the simple pyramidal composition, of the kind Raphael had studied in Leonardo's work, contributes to the sense of the pope's dignity.

In Venice about 1520 Titian (c. 1490–1576) painted a portrait of an unknown young man which shows another aspect of the search for the ideal in the portraiture of the Renaissance. This young man, whose elegance Titian proclaimed in the relaxed pose, the long fingers, the gloves and particularly by the extended “V” of his white shirt, has at the same time a youthful vulnerability. Instead of idealizing the dignity of old age, as Raphael did in his “*Julius II*,” Titian is reminding us of the potentialities of youth; this is a man who may yet form himself into a maturer ideal. Although it is this suggestion of anticipation that makes this work most characteristic of the High Renaissance, it is the elegance of the man and the visual beauty of the arrangement within the painting that had most influence. Artists later in the 16th century, in the style called Mannerist rather than Renaissance, developed this self-conscious grace in paintings of polished and affected beauty. The type spread throughout Europe so that such Italians as Jacopo da Pontormo (1494–1556), Parmigianino (1503–40) and Bronzino (1503–72), such Frenchmen as François Clouet (c. 1515/20–1572), such Flemings as Sir Anthony More (c. 1512–

75) and such Englishmen as Nicholas Hilliard (1547–1619) painted Mannerist portraits.

During the Renaissance artists like Leonardo, Raphael and Titian had positions as courtiers rather than as artisans. This increase in social prestige helped to make the artist more conscious of his own personality. This consciousness accomplished two things: it encouraged the artist to paint portraits of himself and it made him impose himself in some fashion upon portraits he painted of others. Leonardo, Raphael and Titian did not efface themselves before their sitters as did Piero or Van Eyck; instead they revealed their own preoccupations by making these men conform to their particular ideals.

The Self-Conscious Sitter.—The same change in the social position of the artist took place in the north, with the same effects. The German Albrecht Dürer (1471–1528), at 13, was sufficiently aware of himself to make an exquisite silverpoint self-portrait. He later revealed his personal ambitions in paintings of himself. The self-portrait of 1498 (in the Prado, Madrid) shows Dürer in the costume of an elegant young man. Proudly displayed in the background are the Alps the painter had crossed on his way to Italy. In 1505, conscious of the religious troubles of his time, Dürer painted a self-portrait which showed another ideal—the desire to lead a life in imitation of Christ.

Dürer's compatriot, Hans Holbein the Younger (1497?–1543) excelled in superb and rather detached portrait drawings and paintings. His paintings show a desire for elegance, an enjoyment of the description of textures and a delight in the surface of the panel. A portrait such as that of the “*Merchant Gisz*” may at first seem cold and objective. Like Van Eyck in the portrait of the Arnolfini, Holbein indicates the man's environment, his occupation (he is a Hanseatic merchant in the Steelyard in London) and even his habits by the details of the setting, and suggests his dignity and his position by the merchant's bearing and costume. However it soon becomes evident that Holbein is as much concerned with the nature of this man as with such externals. Here there is none of the easy grace of Titian's “*Man With a Glove*.” Indeed Gisz holds himself rather tensely; he looks far to his right, well beyond us, not casually but with an expression which shows apprehension. Holbein uses the ingredients of the setting masterfully, building them around the Merchant Gisz in space so that he is hemmed in one corner. This position, combined with the dark shadow he casts, makes even the gesture of his opening the envelope a furtive one. On the wall is inscribed his appropriate motto: “*No Joy Without Sorrow*.” Holbein tries to remain objective but within the formal restraint he gives his portraits strong emotional overtones which ask the spectator to respond as he once presumably responded before his sitter.

El Greco (1541–1614) did not feel as much need to discipline his responses to his sitters some 66 years later. A comparison of his “*Cardinal Guevara*” with Raphael's “*Julius II*” shows how differently from a Renaissance artist this painter approached an important ecclesiastic. El Greco does everything to destroy the pyramidal order and calm of Raphael's work by choosing an elongated canvas, emphasizing its verticality, showing the figure full length and by giving the red silk of the robe an independent life by the angular and dynamic play of the folds. The cardinal does not sit with the heavy gravity of the pope; instead he perches on the edge of his chair, his feet nervously protruding from beneath his robes, his right hand conspicuously relaxed, the left toying with the arm of the chair. The piece of paper at his feet helps destroy any sense of self-containment. Nor is there any suggestion of spiritual contemplation, for the cardinal looks out with great wariness through his black-rimmed spectacles. He has more in common with Holbein's “*Merchant Gisz*” although he is painted more freely and the emotions are much intensified. In the works of both El Greco and Holbein, like the best 16th-century portraiture after 1530, the emotions in the relationship between sitter and artist predominate.

BAROQUE AND ROCOCO

The Whole Man.—The artists of the late middle ages were interested in man as a symbol; those of the early Renaissance in

Left panel of the "Wilton Diptych" by an unknown artist, late 14th or early 15th century. 18 × 11½ in.

"Federigo da Montefeltro, Duke of Urbino" by Piero della Francesca, c. 1472. 18½ × 13 in. In the Uffizi Gallery, Florence

EARLY PORTRAITS

Medieval portraits, like that of King Richard II of England, above, may have been painted to record their subject's piety. The king is shown kneeling in supplication and surrounded by his patron saints in the left panel of the "Wilton Diptych"; the Madonna and Child are depicted in the right-hand panel (not shown). With the renewal of interest in the individual that characterized the Renaissance, it became fashionable for wealthy men, like the young Italian merchant who appears with his bride, at bottom right, to have their portraits painted in as lifelike a manner as possible. Though the couple stands somewhat stiffly and the seemingly casual details that fill the scene constitute a rebus of medieval symbols of the marriage sacraments, the portrait, by Jan van Eyck, in its brilliant rendering of texture, detail, and the effects of natural light, hints at the naturalism that was to follow. In 15th-century Italy this increasing interest in accurate rendering was put to a new purpose: the glorification of the ideal to which the sitter aspired. Thus Piero della Francesca's portrait of the duke of Urbino (top right) is a highly realistic representation which also conveys the absolute temporal power of a Renaissance prince

"Arnolfini and His Wife" by Jan van Eyck, 1434. 32¼ × 23½ in.

"Merchant Gisz" by Hans Holbein the Younger, 1532. $37\frac{1}{2} \times 33\frac{1}{2}$ in.

"Portrait of the Artist" by Albrecht Dürer, 1498. $20\frac{1}{2} \times 16\frac{1}{2}$ in.

"Man with a Glove" by Titian, c. 1520. 39×35 in. In the Louvre, Paris

"Julius II" by Raphael, c. 1511-13. 42 × 31½ in. In the Uffizi Gallery, Florence

RENAISSANCE PORTRAITS

Portrait painters of the High Renaissance were increasingly intrigued by the abstract ideals which their sitters could be made to personify. Meticulous attention to specific detail of the kind that characterized the work of Van Eyck (Plate I) became less important than the search for the generalized ideal, and Late Renaissance portraits still manage to convey to the modern eye the ideals that inspired them. Thus, the serene and contemplative gaze of the militant Pope Julius II by Raphael (above) still evokes the weary dignity of old age, while the "Man with a Glove" by Titian (Plate II, bottom) conveys the promise of youth in his graceful pose and eager look. Enhanced social prestige helped make the Renaissance artist increasingly aware of, and fascinated by, his own personality. His emotional reactions to the sitter, favourable or unfavourable, became of great importance to him, causing Hans Holbein to paint a Hanseatic merchant (Plate II, top left) as he saw him rather than as the sitter saw himself, and El Greco (right) to paint a frank portrait of an ostensibly spiritual cardinal. Albrecht Dürer's 1498 self-portrait (Plate II, top right) shows, in its elegant dress and introspective look, the Renaissance spirit of self-awareness.

"Cardinal Don Fernando Niño Guevara" by El Greco (1541-1614). 67¼ × 42½ in.

"Innocent X" by Diego Velázquez, 1650. 55½ × 47¼ in. In the Galleria Doria, Rome

BAROQUE PORTRAITS

Baroque portraitists, in seeking to present the total man, synthesized the aims of the artists who preceded them. They sought simultaneously to render accurately, record their own emotional response to the sitter, and express the ideals which their sitters seemed to personify. Thus, Velázquez in his portrait of Innocent X (left) portrayed a pope who is at once ugly and magnificent. Rembrandt evoked the spiritual beauty within an unattractive woman (Plate V), and Anthony van Dyck (below) made an elegant figure of a powerful king.

"Charles I" by Anthony van Dyck, c. 1638. 107 × 83½ in. In the Louvre, Paris

"Lady with a Pink" by Rembrandt van Rijn, c. 1655. $36\frac{1}{4} \times 29\frac{3}{8}$ in.

"Baron Schwiter" by Eugène Delacroix, 1826. 85 $\frac{3}{4}$ x 56 $\frac{1}{2}$ in.

"Mme Maitessier (Seated)" by J. A. D. Ingres, 1856. 47 $\frac{1}{4}$ x 36 $\frac{1}{4}$ in.

18TH- AND 19TH-CENTURY PORTRAITS

The English 18th-century portraitists, of whom Thomas Gainsborough (Plate VII, top right) was among the most gifted, sought, through flawless execution and graceful pose, to increase the sitter's stature. John Singleton Copley (Plate VII, bottom right), Gainsborough's American contemporary, represented a different and more realistic strain, painting straightforward likenesses without flattery. Just as Gainsborough and Copley represented the romantic and realistic poles in the 18th century, so to a considerable degree did Eugène Delacroix (top left) and J. A. D. Ingres (above) represent them in the 19th. However, Delacroix tempered his essential romanticism with some characteristically realistic touches (like the shy vulnerability of his otherwise elegant subject) while Ingres, though meticulously exact in rendering his sitter's likeness, emphasized her feminine curves and relaxed pose to produce an essentially seductive effect. Édouard Manet (left), like other painters associated with the Impressionists, was interested neither in flattery nor realism but rather in the purely visual problems that a portrait posed. John Singer Sargent (Plate VII, left) carried the fashionable romantic tradition of elegant flattery into the early 20th century.

"Victorine Meireux" by Édouard Manet, c. 1875. 17 x 17 in.

"Madame X (Mme Gautreau)" by John Singer Sargent, 1884.
82½ × 43¼ in.

"Mrs. Graham" by Thomas Gainsborough, c. 1777. 93½ × 60¼ in.

"Mrs. Seymour Fort" by John Singleton Copley, c. 1780. 24 × 19 in.

"Duke and Duchess of Morbilli" by Edgar Degas, c. 1865. 20 x 17 in.

"Jacques Lipchitz and His Wife" by Amedeo Modigliani, 1916. 31 x 21 in.

"Portrait of a Lady" by Pablo Picasso, 1937. 24 x 11 in.

LATE 19TH- AND EARLY 20TH-CENTURY PORTRAITS

The three portraits on this Plate show the increasing interest in psychological complexity that has characterized much modern portraiture. In the Edgar Degas portrait of the Duke and Duchess of Morbilli (top left), painted in c. 1865, may be seen a conscious effort to portray both individuals as well as something of the relationship between them. Amedeo Modigliani (top right), about 50 years later, in 1916, felt free to eliminate superfluous detail and concentrate on the essentials that reveal more completely the personalities of the sitters, sculptor Jacques Lipchitz and his wife. A comparison of these portraits with the Van Eyck portrait of Arnolfini and his wife, which appears on Plate I, shows how far inward artists have turned since the Renaissance. In the portrait by Pablo Picasso (left), the artist has radically altered the appearance of the sitter for his own artistic ends, portraying her from several vantage points at once, as if simultaneously to reveal as many facets of her personality as possible.

the facts of his appearance and position; those of the High Renaissance in him as an expression of an ideal and the Mannerist painters of the 16th century in his emotional responses. But it was not until the 17th century, in the period called the baroque, that any artist tried to embrace all these approaches in a single portrait. Certainly the Flemish Peter Paul Rubens (1577-1640) and the Dutch Frans Hals (c. 1580-1666) accomplished this—but it was the Spaniard Diego Velázquez (1599-1660) who succeeded most impressively in his portrait of Innocent X. The pope in his dress, in his throne and in his bearing is a symbol of papal authority if not of infallibility. The facts of his appearance, no matter how ugly, are recorded here although they in no sense destroy the total impression. The ideal that Innocent X represents is far from the Renaissance ideal—but it is a magnificent expression of the physical and intellectual and moral force to which the baroque aspired. Velázquez is as much concerned as Holbein or El Greco with emotional relationships, but his are not so subtle or so strained; Innocent X challenges us with his penetrating look. Velázquez, with his remarkable ability to give the illusion of this dynamic man in space, has made a characteristically baroque effort to present the total man.

Velázquez' contemporary in Protestant Holland, Rembrandt van Rijn (1606-69), normally painted far gentler, humbler people but also tried to arrive at the synthesis of the complete man or woman. One of his late paintings, "Lady With a Pink," records the facts of his sitter's weariness and age and, by the position of her head and hands, suggests her shyness and humility. Like Leonardo, Rembrandt was interested in the spirit within such a woman, but here this radiates warmly and not coquettishly through a physical shell which in itself is a revelation of this woman's experience. Her beauty seems completely spiritual, the result of a moral life rather than of a physical ideal; Rembrandt expresses it in the gentle, worn face, the large, tender eyes and particularly in the light which seems to be the equivalent of her soul. Rembrandt's judgment of his sitters is ultimately a moral one.

One of the most influential portrait painters in Europe in the 17th century was the Flemish Sir Anthony Van Dyck (1599-1641). Like Rembrandt and Velázquez, Van Dyck was interested in an illusion of the total man revealed in a moment of contact. However, his ideal was more like that of the early Titian whose work he admired.

As can be seen in his portrait of Charles I of England (1600-49), to whom Van Dyck was court painter, he could suggest the easy grace, the elegance and the arrogance of this man through the swing of the body, the texture of the dress, the haughty expression of the features. The casual landscape setting, the grooms with the horse, also contribute to the sense of the grace of the king, so accidentally discovered with them. Van Dyck brought this tradition of the courtly portrait from 16th-century Venice to England where it was developed in the 18th century by such painters as Sir Joshua Reynolds and Thomas Gainsborough.

The Sitter Romanticized.—France had several artists in the 18th century, including Jean Baptiste Chardin (1699-1779), Maurice Quentin de La Tour (1704-88) and Jean Baptiste Perroneau (1715-83), who drew sensitive heads in pastel (*q.v.*) which show a lightness of touch which was appropriate for the period called rococo. But it was England that had the most substantial sequence of portrait painters; their names form an imposing list: William Hogarth, Sir Joshua Reynolds, Thomas Gainsborough, Joseph Highmore, Allan Ramsay, Sir Henry Raeburn and George Romney. Of these, Reynolds (1723-92) was the most verbally articulate and, before the Royal Academy of which he was the first president, he made a series of discourses about art in general with several asides on portraiture which he, like his age, regarded as a form of art inferior to history painting. During his fourth discourse he said of the portrait painter: "He cannot make his hero talk like a great man, he must make him look like one." And essentially this was the attitude of most of these English portrait painters—to emphasize, with certain visual conventions and exaggerations, the stature of the sitter. Reynolds did it himself, most convincingly in his portraits of such men as Samuel Johnson.

Gainsborough (1727-88) was perhaps the most gifted of these painters and, although many of them were influenced by Van Dyck, his style was closest. He applied paint with the fluidity of Van Dyck. His work has a similar luminosity which seems, in itself, to give his portraits great distinction. Like Van Dyck he normally painted his sitters out-of-doors—although for the landed aristocracy of 18th-century England those parklike settings probably had more meaning in terms of prestige than they had had a century earlier. And he took certain conventions which Van Dyck had used to flatter his sitters and exaggerated them further to give the most aristocratic impression. In his portrait of "Mrs. Graham," for example, Gainsborough emphasized her proud dignity by elongating her body and by emphasizing the vertical through her long, graceful throat, the right arm and even the supporting pillar. She is spatially and psychologically sufficiently removed to remain appropriately remote. Her beauty is suggested by her exquisite features and by the shimmer of her garments, echoed in the romantic light of the sky. Finally the casualness of such an aristocratic ideal is indicated by the informal way Mrs. Graham leans on the pillar and looks without concern in another direction.

Eighteenth-century England was invaded periodically by American artists. Two talented portrait painters remained there. One of them, Benjamin West (1738-1820), became president of the Royal Academy. The other, John Singleton Copley (1738-1815), painted good, straightforward paintings which seem far removed from Gainsborough's romanticized portraits. When Copley painted "Mrs. Seymour Fort" he may have used the device of the baroque red curtain in the background and shown her in a position of considerable dignity—but with the crocheting in her hand, her solid body and good-humoured face, she represents all the most sensible middle-class virtues, presented without flattery, satire or rationalization.

19TH AND 20TH CENTURIES

Realism.—In France during the first half of the 19th century there were two strains in painting comparable with those Gainsborough and Copley had represented in the 18th. Eugène Delacroix (1798-1863), when he painted his 21-year-old friend, the Baron Louis Schwiter, continued the strain in European painting which runs from the Venetians through Van Dyck to Gainsborough. Consistently he painted the full figure of this rather elegantly dressed young man, standing in a park with a poetic light breaking across the sky. However at the same time with a characteristically 19th-century realism Delacroix portrays the baron's essential vulnerability. His hands and the position of his feet, the untidy hair and collar convey his helplessness. And because he stands so simply and directly and because Delacroix has raised the horizon so that, unlike a portrait by Van Dyck or Gainsborough, the viewer is put almost on a level with him, the impression is given that this rather gentle, shy figure of Baron Schwiter has been exposed because he has been too passive to resist or to care. In the very lack of assertiveness or definition, which makes it possible for him to be such a harmonious part of the idyllic setting, the baron seems to represent at least one romantic ideal.

Just as Copley's "Mrs. Seymour Fort" is the antithesis of Gainsborough's "Mrs. Graham," so "Mme Moitessier" by Jean Auguste Dominique Ingres (1780-1867) is the antithesis of Delacroix's "Baron Schwiter." As substantial as Mrs. Fort and as elaborately dressed, Mme Moitessier is decisive, assertive and meets our eyes with a challenge. Ingres, with the examples of Roman painting and of Raphael in mind, found every excuse for curves which would emphasize the firmness and roundness of her body; these combined with the relaxed pose make Mme Moitessier essentially seductive. Throughout his career Ingres painted and drew many portraits as meticulous and direct.

The portraitist in the second half of the 19th century in France who perhaps most completely understood both Delacroix and Ingres, and learned from each, was Edgar Degas (1834-1917). His early portrait of his sister and brother-in-law, "Duke and Duchess of Morbilli," shows an indebtedness to Ingres in the relative precision and boldness of the work but also something of the

quality of Delacroix in the hesitancy of both husband and wife before the spectators. However, Degas was most conscious of the psychological complexities and tensions in the relationship of two human beings to each other—and in their relationship to the world. Although the work possesses almost the formality of a daguerreotype, Degas makes use of the positions of the figures in relation to each other and in space, their expressions and particularly their gestures to make the nature of their adjustment to each other and to society quite clear. Later Degas found a more personal visual vocabulary to convey the same kind of meaning in his portraits, which influenced such painters as Vincent van Gogh (1853–90) and Henri de Toulouse-Lautrec (1864–1901).

Degas' contemporary and friend Édouard Manet (1832–83) painted portraits which are psychologically uncomplicated, straightforward, but most remarkable, like all his paintings, for their sheer visual beauty. Like Manet, other painters associated with the Impressionists were less concerned with subject matter than with certain visual problems. Even Paul Cézanne (1839–1906), who painted some beautiful portraits, was only incidentally concerned with recording the appearance, personality or virtues of any particular person; his paintings had another function. It might be argued that the decline in the interest of the finest painters in portraiture was a result of the decline in patronage.

However, at the same time that Degas and his friends were receiving little encouragement, there were fashionable portrait painters throughout Europe who made fortunes from this form of art. Perhaps the best of these was the U.S. expatriate, John Singer Sargent (1856–1925). Sargent may have suffered somewhat from his generous patronage; indeed he eventually reacted against it and refused to paint more portraits. Whereas the most creative artists of the 19th century—Goya, David, Corot, Daumier, Millet, Courbet, Whistler, Eakins, Renoir, besides those already mentioned—revealed an underlying realism and a desire to present the sitter as unpretentiously as possible, Sargent fulfilled his sitters' desires to be ravishingly beautiful or forcefully handsome. In such paintings as "The Wyndham Sisters" he succeeded in giving an illusion of the most beautiful and animated of young women in a work of great brilliance and bravado. Sargent has survived the criticisms of the 20th century more satisfactorily than such fashionable rivals as Giovanni Boldini (1845–1931) or Philip Alexius Laszlo de Lombos (1869–1937). However, a market for their kind of portraiture still exists.

The 20th Century.—In the first half of the 20th century, even more than during the 19th, the most penetrating portraits have not been the result of commissions of the kind Sargent received. Amedeo Modigliani (1884–1920), an Italian living a poverty-stricken and bohemian life in Paris, painted many of the most successful portraits of this period—but usually of his friends; they might pay him, but he demanded only a paltry sum. The sculptor Jacques Lipchitz (1891–) has written that when he was newly married and he and his wife decided to have their portrait painted by Modigliani, the painter asked ten francs a sitting and insisted it was finished after the first. Lipchitz, in his embarrassment, persuaded Modigliani to work on it longer; however, the sculptor acquired his portrait for a modest sum.

Lipchitz has also written that the pose for this double portrait was inspired by their wedding photograph; this makes it particularly appropriate to compare it with Degas' portrait of the Morbillis, which must have been based upon some daguerreotype. Probably a comparison of the photographs, as much as a comparison of the paintings, would reveal how much more casually and informally the Lipchitzes were living than the Morbillis had three decades earlier. It is not just that the sculptor wears a turtle-neck sweater or has a hand cockily in his pocket or that the picture behind him on the wall is tilted precariously. It comes out in their perfect ease with the spectators, and even more tellingly in their casual intimacy with each other. Lipchitz places his hand protectively on her shoulder and she leans her head back on his chest with supreme confidence in him and in herself. None of the tensions of the Degas portrait seems to exist.

There is nothing photographic about this double portrait even if a photograph was the source for the composition. Modigliani

makes use of visual abstractions, particularly pattern, to interpret this husband and wife. The beautiful oval of the woman's face opens up sensually whereas the features of the husband's face are smaller, cramped and more ingrown. In depending upon such abstractions Modigliani was able to eliminate irrelevant detail, to simplify the work and therefore to concentrate upon those essentials which could suggest their separate personalities, their relationships to each other and to the rest of the world more perfectly than any wedding photograph could.

Twentieth-century portraiture, like all 20th-century art, has been affected by the Freudian analysis of the personality, as is seen in "A First Sketch for the Spectre of a Genius" by the Swiss painter Paul Klee (1879–1940). The work is a pathetic commentary upon the lack of balance in emotional, physical and spiritual growth of the genius.

Of all 20th-century painters Pablo Picasso (1881–) has been the most creative in the discovery of new visual vocabularies to convey the character of a sitter. He has drawn and painted as meticulously and as representationally as Ingres or he has departed as far from the conventional as it seems possible for a painter to do without losing a sense of the thing portrayed. His responses to people in his portraits have been sentimental, cynical, calm, analytical or morally indignant, in each case representing an attitude characteristic of a part of 20th-century society.

In his "Portrait of a Lady" (1937) Picasso continued, as he had for 30 years, to destroy the conventional integrity of the body for his own expressive purposes. With colour, pattern, line and important allusions to anatomy, Picasso makes it apparent that a classically beautiful woman is seated, with a certain aplomb, in brilliant sunshine. She seems a typical 20th-century sophisticate in her informality, the smart dress, the lacquered nails and the hand which toys with her long hair. But Picasso was not content to describe her only socially; he designed her dress so that her jacket opens to reveal lines like stamens fanning out to her petal-like breasts; this floral motif seems carried out in the hands. It does not seem improbable that Picasso, with great restraint, is suggesting her sexual urges. But the most startling area is the face. The eye on the left is the strange and frightening red of something possessed; the quieter green eye on the right seems to have turned on itself to regard the other with disturbance and surprise. It is as if this woman, so suave externally, has suddenly become aware of the unknown world of her unconscious. Picasso, like the 20th-century novelist or psychologist, makes the accepted breakdown of the barriers between the normal and the abnormal, the unconscious and the conscious quite explicit. The Surrealists, such as Giorgio de Chirico (1888–), Max Ernst (1891–) and Yves Tanguy (1900–55), delved even more obviously into Freudian realms.

The Judgment of Quality in Portraiture.—How can the quality of a contemporary portrait be determined without the selective critical process of generations? A great portrait painting must be, first of all, a great work of art; this means that every brush stroke will have a structural role in the total painting and will, at the same time, express the attitude of artist toward sitter. The abstract elements must have a vitality of their own which seems to be the consequence of the creative activity of a painter whose whole being is absorbed in the process. As completely different as such artists as Piero della Francesca, Velázquez or Picasso may be, every part of their work operates in producing visual relationships which make their sitters seem physically and spiritually alive. The portrait, a very difficult form of art, presents other problems about which it is perhaps rash to generalize. However, in all great portrait paintings the suggestion of the intelligence of the sitter seems to surmount the handsome costumes, elaborate settings or an unusual style. Even in Picasso's portraits from the most difficult of all his periods, analytical Cubism, the sense of the particular intelligences of sitters, as in his portraits of Ambroise Vollard, Wilhelm Uhde and Daniel Henry Kahnweiler, is finally triumphant. The great portrait, whatever the period, seems to be the product of the painter's imagination before a sitter whom this painter, because of his temperament and background, is fully able to understand. Being the product of the painter's imagination, it is thus strange to his contemporaries and impossible to anticipate.

(J. S. Bs.; X.)

PORT ROYAL, an island of Beaufort County, S.C., U.S., 50 mi. (80 km.) SW of Charleston, one of the Sea Islands. It is about 17.5 mi. (28 km.) long and 7.5 mi. (12 km.) wide. The principal city is Beaufort, a port of entry and seat of Beaufort County. The town of Port Royal is on the southern tip of the island, 5 mi. (8 km.) S of Beaufort; its population is 686. Major occupations of the area include fishing, shrimp and crab processing, cypress and pine lumbering, cattle and cotton farming, and employment at nearby Parris Island, a U.S. Marine Corps installation devoted primarily to the basic training of enlisted personnel. Old plantation homes, vast oaks covered with Spanish moss and nearby beaches make Port Royal an exotic resort area.

The port was named Santa Elena by Spanish explorers in the early 16th century. In 1562 the French Huguenot Jean Ribault, seeking a haven for French Protestants and a privateering base against Spanish shipping, renamed it Port Royal and left 30 settlers on Parris Island, three miles from the present town of Port Royal. Neglected by Ribault, after two years the settlers killed the commander he had left in charge, built a tiny ship and returned to Europe. The Spanish occupied the area more or less continuously from 1566 to 1650, maintaining garrisons and Indian missions. English claims to Carolina grew with the settlement of Charleston in 1670, and in 1684 Henry Erskine (Lord Cardross) led 51 Scottish Covenanters to Stuart's Town, 1 mi. N of the present town of Port Royal. Charlestonians looked upon the Scots as trade rivals and ignored pleas for help when Stuart's Town was destroyed by Spanish and Indians in 1686. Gradually planters moved into the area, and in 1710 Henry Somerset (duke of Beaufort) established the present town of Beaufort. In Jan. 1779, during the American Revolution, the British occupied the area but were dislodged the following month. After the Revolution the Port Royal environs became the centre of opulent rice and cotton plantations, and scores of magnificent ante-bellum homes attest to this golden age. Early in the American Civil War, on Nov. 6-7, 1861, a fleet of 56 Union vessels, and 12,000 men under Gen. Thomas W. Sherman, reduced the Confederate fortifications and used the port as a Union coaling and repair station for the remainder of the war. Northern abolitionists, supported by the U.S. government, conducted the Port Royal experiment during and immediately after the war, confiscating the lands abandoned by white planters and seeking, with mediocre success, to educate the former slaves of the area and give them control over local lands and government. See also SEA ISLANDS.

(G. H. Ct.)

PORT ROYAL (PORT-ROYAL DES CHAMPS), a celebrated abbey of Cistercian nuns, was the centre of Jansenism (q.v.) and of literary activity in 17th-century France. It was founded about 1204 as a Benedictine house by Mathilde de Garlande on a low, marshy site in the valley of Chevreuse, seven miles south of Versailles. Its church was built in 1230.

In 1609 the young abbess Jacqueline Marie Angélique Arnauld began a much-needed reform. However, the unhealthiness of the site drove her, in 1626, to establish her community in Paris, in the Faubourg Saint-Jacques, where new buildings were erected, including a Baroque church. In 1638 the deserted building was occupied by the *Solitaires* (hermits), pious laymen or secular priests living without vows or definite rule under the spiritual guidance of Jean Duvergier de Hauranne (q.v.), abbot of Saint-Cyran and friend of Cornelius Jansen. Among them were several members of the Arnauld (q.v.) family. Several times the *Solitaires* were forced by persecution to leave. In 1648 a group of nuns returned to occupy the buildings; the *Solitaires* moved to Les Granges nearby and there started the Petites Écoles de Port Royal, which provided a type of education differing in important ways from that

of the Jesuits. Jean Racine was a pupil there.

In 1665 most of the nuns of Port-Royal de Paris, having refused to sign the fomulary condemning Jansen, were sent to Port-Royal-des-Champs, where they underwent a kind of captivity, deprived of all sacraments. The *Solitaires* were dispersed and went into exile or hiding. However, in 1669 the Peace of Clement IX, or Peace of the Church, was concluded and ten years of calm followed. The houses of Paris and Les Champs were finally separated, and the latter enjoyed the protection of the duchesse de Longueville, cousin of Louis XIV. After her death in 1679 persecution was renewed, the community was forbidden to receive novices, and it declined in numbers. The last abbess but one was Agnès de Sainte-Thècle, aunt of Racine. In 1705 the bull *Vineam domini* of Clement XI renewed measures against Jansenists, and the remaining 17 nuns refused to submit. On Oct. 29, 1709, the community was dispersed and the nuns exiled to various other convents. In 1711 the buildings and cemetery were completely destroyed and the bones of the buried thrown into a hole in the cemetery of Saint-Lambert.

In 1824 the land was bought by the lawyer Louis Silvy out of devotion to the memory of Port Royal. After his death the property was transferred to the Society of St. Augustine, which became the Society of Port Royal. The ruins of the church were uncovered and a small museum built. Port-Royal-de-Paris became a prison during the Revolution. In the 19th century the Hôpital de la Maternité was installed there. The buildings are in perfect state of preservation and both chapter house and choir have been restored. See also JANSENISM, with bibliography.

BIBLIOGRAPHY.—The following books deal with Port Royal primarily as a historical monument: L. F. Hérard, *Recherches archéologiques sur l'abbaye de Port-Royal des Champs* (1881); H. Mabille, *L'Eglise de Port-Royal des Champs* (1901); A. Hallays, *Le Pèlerinage de Port-Royal* (1925); C. Gazier, *Histoire du monastère de Port-Royal* (1929). See also R. A. Knox, *Enthusiasm* (1950).

(L. Co.)

PORTRUSH, an urban district and seaside resort of County Antrim, Northern Ireland, lies 6 mi. (9.7 km.) N of Coleraine at the end of the Antrim Coast Road. Pop. (1961) 4,265. It is situated on the basaltic peninsula of Ramore Head, with magnificent sandy beaches and deep bays on either side. There is a harbour on the western side. Out to sea lie the Skerries (rocks) forming a natural breakwater. The Giant's Causeway (q.v.) is 7 mi. (11.3 km.) E along the coast beyond the White Rocks, with their caves, and Dunluce Castle (14th century), standing on a rock separated by a chasm spanned by a footbridge. Portrush caters principally to tourists; it has three golf courses and spacious recreation grounds. There are salmon fisheries and a whitefish trade.

(W. R. Sh.)

PORT SAID (BUR SA'ID), the second seaport, and one of the four urban *muhafazat* (governorates), of Egypt (United Arab Republic), is situated at the northern end of the Suez Canal, 145 mi. (233 km.) NE of Cairo by rail. Pop. (1962 est.) 259,000. The town lies on the western side of the canal on the low sandy strip of land which separates the Mediterranean from Lake Manzala (Buhayrat al Manzilah). This land was raised and extended by the draining of part of the lake and by material excavated from the inner harbour and main channel. Port Fouad (Bur Fu'ad) on the opposite bank between the Mediterranean and Al Mallaha Lagoon (Tawwal al Mallahah) is a residential quarter of more recent growth. The outer harbour, or roadstead, is about 4 mi. (6.4 km.) long and is formed by two protective jetties, or breakwaters, the western one carrying a lighthouse 174 ft. (53 m.) high. The main channel of the port, 2½ mi. (4 km.) long and flanked by open basins, curves through a 40° angle to the beginning of the canal, where for 1½ mi. (2.4 km.) a parallel second channel permits the forming of southbound convoys prior to their entry into the canal proper.

Port Said, named after Said Pasha, dates from 1859, the year in which the construction of the canal was begun. Originally it depended entirely upon the canal traffic, becoming the largest coal-ing station in the world and later an important oil-bunkering port. After 1902 increasing quantities of raw cotton and subsequently rice were exported from the eastern provinces of the delta, the cotton traveling by boat from Al Matariyah across Lake Manzala.

J. ALLAN CASH

THE WATERFRONT OF PORT SAID WITH DOMED HEADQUARTERS OF THE SUEZ CANAL ADMINISTRATION IN THE BACKGROUND

Since 1904, when the standard-gauge railway from Cairo was completed, Port Said has been in a position to compete with Alexandria and now mainly exports onions, cotton, rice, and salt. There is a separate fishing harbour, and the area contains salt works and the main workshops of the canal administration. (A. B. M.)

PORTSMOUTH, LOUISE RENÉE DE KÉROUALLE, DUCHESS OF (1649–1734), French mistress of Charles II of England, was born near Brest, in Brittany, in September 1649, the daughter of Guillaume de Penancoet, sieur de Kéroualle. She entered the household of Henrietta Anne, duchesse d'Orléans, the sister of Charles II, in 1668 and accompanied her to England in May 1670 for the festivities which disguised the secret Treaty of Dover. She soon aroused the king's interest and the sudden death of Henrietta (June) released her for a return to the English court.

Louise's career, however, more than that of any other of Charles's mistresses, was fostered for political reasons. The French ambassador, Colbert de Croissy, and Lord Arlington, the principal secretary of state, united in promoting her for the sake of French interests and it was at the latter's country house at Euston, in Suffolk, that their intrigue was consummated in October 1671. A son, Charles Lennox, later duke of Richmond, was born in July 1672. Louise continued in favour for many years; her English titles were bestowed in 1673, and in 1674 she was assured of an income of at least £10,000 a year. She proved skilful in safeguarding her position through leading politicians such as the earls of Danby, Sunderland, and Shaftesbury, and used her considerable influence with the king on their behalf. However, her unequaled rapacity made her unpopular, and in 1678 her Roman Catholic, French connection placed her in some danger during the "Popish Plot" (see ENGLISH HISTORY). Nevertheless she remained close to Charles until his death (Feb. 6, 1685), and she may have assisted in his reception into the Roman Catholic Church. She was not made welcome by James II and much of the remainder of her long life was spent in France. She died in Paris on Nov. 14, 1734. Of all Charles II's mistresses, Louise de Kéroualle was the least popular with his subjects and the most able politician, though it cannot be shown that she exercised any decisive influence on his policies.

See H. Forneron, *Louise de Kéroualle* (1886).

(H. G. Ro.)

PORTSMOUTH, a city, county and parliamentary borough, the premier naval base of the British Commonwealth, and (with Southsea) a popular holiday resort, in Hampshire, Eng., lies 73 mi. (117 km.) SW of London by road. Pop. (1961) 215,077. It is the seat of an Anglican and a Roman Catholic bishop.

The naval station and Royal Dockyard (known colloquially as

"Pompey") occupy the southwestern part of Portsea Island, which lies between Portsmouth Harbour and Langstone Harbour, inlets of the English Channel. The island is connected to the mainland by road and railway bridges. Portsmouth Harbour opens into Spithead, the eastern end of the Solent (q.v.), which separates the Isle of Wight from the mainland. The four conspicuous masonry forts in Spithead were built in the 1860s as part of the port defenses. Portsmouth Harbour widens inward in bottle form, with Portsmouth on the east shore and Gosport (q.v.) on the west. Hayling Island lies east of Langstone Harbour.

Portsmouth extends to the northern mainland, including Cosham, Paulsgrove, Drayton, Wymering, and Farlington, north of which the chalk ridge of Portsdown (400 ft. [122 m.]) commands a view of the city and harbours. Portsmouth suffered severe bomb damage in World War II, but substantial clearance and rebuilding have taken place. The dockyard, which is the principal employment centre, dates from 1496, when the town was already a naval station. It was greatly expanded after 1698 and now covers more than 300 ac. (121 ha.), with four large dry docks and 75 ac. (30 ha.) of fitting and repairing basins. There are numerous naval establishments, and a Royal Marine headquarters at Eastney.

Portsmouth owes its origin to the retreat of the sea from Portchester at the head of Portsmouth Harbour. No town existed until 1194, when the strategic importance of Portsea Island induced Richard I to build one and to grant a charter, fair, and market to the inhabitants. The borough is governed by a charter granted by Charles I in 1627, modified by later municipal acts.

The holiday and tourist trade, which is centred primarily on Southsea, attracts more than 150,000 staying visitors and 500,000–800,000 day tourists annually. The resort area, with a broad sweep of grassland (Southsea Common) adjoining the beach and promenades, includes two piers, fine seafront gardens, and sports areas. Industries include shipbuilding, aircraft engineering, and the manufacture of corsets, cardboard boxes, brushes, refrigerators, sweets, and baby products. The commercial port at Camber Docks near the harbour entrance and the airport in the northeast part of Portsea Island are municipal.

Lord Nelson's flagship at the Battle of Trafalgar, HMS "Victory," occupies a small dry dock in the dockyard and is a major tourist attraction, and the nearby Victory Museum contains many relics of Nelson. The spacious guildhall, reconstructed after having been gutted by enemy action in 1941, was reopened by Queen Elizabeth II in 1959. It serves as civic headquarters and as a concert and conference hall. Other notable buildings include the cathedral (the former parish church, dating in part to the 12th century), several dignified buildings of the 18th and early 19th centuries in the dockyard, Southsea Castle, and the birthplace of Charles Dickens at 393 Commercial Road (now a museum). Other distinguished natives of Portsmouth were George Meredith, Sir Walter Besant, Isambard Brunel, the philanthropist Jonas Hanway, and the cobbler John Pounds who started a "ragged school."

Passenger steamers and car ferries from Portsmouth serve Ryde and Fishbourne, Isle of Wight. The parliamentary borough is divided into Langstone, South, and West divisions, each returning one member. Portsmouth became a county borough in 1888 and a city in 1926, with a lord mayor in 1928.

PORTSMOUTH, a city of New Hampshire, U.S., named after Portsmouth, Eng., is New Hampshire's oldest settlement, second oldest city, first capital and only seaport. Situated on the Piscataqua river near its entrance into the Atlantic ocean, it is about 60 mi. N. of Boston, Mass., and about 50 mi. S.W. of Portland, Me. Known as the Old Town by the Sea and the Queen of the Piscataqua, it is rich in historic associations and on its winding streets, tree-shaded and narrow, there are still examples of prerevolutionary architecture, ranging from the earliest simple salt-box style to the dignified 18th-century mansions, tall and square, built on the profits of the city's 18th-century shipbuilding and sailing trade.

Only three years after the Pilgrims settled at Plymouth a fishing settlement was planted 2 mi. E. of the present city. The next year (1624) settlement was made at Portsmouth proper, called

successively Piscataqua and Strawberry Bank and finally in 1653 incorporated under its present name. Portsmouth was the seat of the provincial government of New Hampshire and the home of the famous Wentworth family which furnished two royal governors. Adjacent New Castle was the scene of one of the earliest military events of the Revolution in the patriot capture of Ft. William and Mary from the British in 1774.

In the first half of the 19th century Portsmouth suffered a gradual decline of its commerce and settled down to its present status of a trading centre and home of small industry. The continuance and growth of one of the first U.S. navy yards, dating from the 1790s, has been important as a major economic support for the area. Although it is actually on Seavey's Island in the river (and so in Kittery, Me.) the establishment is known as the Portsmouth Navy yard. There in 1905 treaty negotiations ended the Russo-Japanese War. In the 20th century the yard became a centre for the building and repair of submarines. Connected with it are a naval hospital and a naval prison. The development of the large Pease air force base in Newington, just outside Portsmouth, has also been of great economic advantage to the area.

Portsmouth is located on a famous coastal highway, and for more rapid travel north and south the New Hampshire and Maine turnpikes are easily accessible. The city has a council-manager form of government, in effect since 1948. For comparative population figures see table in NEW HAMPSHIRE: *Population*.

(A. R. F.)

PORTSMOUTH, a city of southern Ohio, U.S., on the Ohio river at the mouth of the Scioto; the seat of Scioto county. The city is protected by a \$10,000,000 flood wall 27 ft. above the flood stage of the Ohio river, which was completed in 1950. Founded in 1803 by Maj. Henry Massie, a land speculator from Goochland county, Va., Portsmouth was incorporated as a town in 1815 and as a city in 1851. While it shared in the down-river flatboat trade in agricultural produce from the beginning, its real importance dates from the opening of the Ohio and Erie canal in 1832, when it became a point of transfer from canal barges to river packets. During the remainder of the steamboat era, it was a typical river town. When steamboating declined, it became an important railway centre. From the industrial point of view, it has been noted for the manufacture of pottery, shoes and especially iron and steel. There are large sandstone quarries in nearby ravines which have supplied material for many important structures, including the Canadian parliament buildings at Ottawa. After 1952 Portsmouth's economy was greatly stimulated by the building and operation of a gaseous-diffusion plant of the Atomic Energy commission near Piketon, 25 mi. N. Some notable earthworks of the mound builders are in and near Portsmouth. There is a branch of Ohio university in the city. Portsmouth has a council-manager form of government, in effect since 1930. For comparative population figures see table in OHIO: *Population*.

(R. L. J.)

PORTSMOUTH, a port city in southeastern Virginia, U.S., on the south shore of the Elizabeth River (an estuary of Hampton Roads), opposite the city of Norfolk (*q.v.*), with which its history has been closely associated; the seat of Norfolk County until the latter became part of the newly organized city of Chesapeake in 1963. Portsmouth was settled in 1752 by people interested in trade but after the American Revolution the town refused to permit the settlement of British merchants. The Norfolk Navy Yard was established in Portsmouth by the U.S. government in 1801. In 1855 the population was decimated by yellow fever. When Federal troops evacuated the Navy Yard in 1861 the South fell heir to great stores of equipment and built the Confederate iron-clad "Virginia" from the hull of the scuttled USS "Merrimack." The yard was recaptured by the Federals in 1862. Portsmouth received a city charter in 1858 and has a council-manager form of government, in effect since 1917.

Portsmouth, a part of the port of Norfolk, has oil and railroad terminals and enjoys steamship connections with world ports. The giant Navy Yard is the principal industrial employer but private shipbuilding yards and railroad shops are important. Portsmouth's manufactures include chemicals, plastics, fertilizer,

machine tools, railroad equipment and peanut butter. The Intracoastal Waterway runs southward past Portsmouth to the Dismal Swamp, a haven for hunters and naturalists. The city has a Little Theatre group, a concert association, three swimming lakes, supervised public playgrounds and a naval museum, and is the site of Frederick College (1958), a private college for men. Pop. (1960) 114,773; Norfolk-Portsmouth standard metropolitan statistical area (see NORFOLK), 577,504. For comparative population figures see table in VIRGINIA: *Population*.

(G. M. BE.)

PORT SUDAN, the principal seaport of the Republic of the Sudan, lies on the west coast of the Red Sea, about 700 mi. (1,127 km.) S of Suez by sea and 490 mi. (789 km.) NE of Khartoum by rail. Pop. (1965 est.) 78,940, half being Arab or Nubian Sudanese (many of Nile Valley origin), with large numbers of indigenous Beja and West Africans, and a small European minority; Asian traders are prominent. Port Sudan was built in 1908 to replace Sawakin, the historic Arab port on a lagoon farther south (now coral-choked and in ruins). The harbour is in the mouth of a gulf continuing seaward through the fringing reefs in a straight, coral-free channel, 10 to 14 fathoms deep, marked by two light-houses. On the northeast side of the inlet are the customhouse, dockyard, main quays (depth 30-35 ft. [9-11 m.]) with cranes and railway sidings, offices, and warehouses; new deepwater berths were constructed in the 1950s and early 1960s. The fuel dock is on the west side of the inlet, south of the town. A causeway carries a road and railway from the main docks to the town, from which the Nile Valley at Atbara is 295 mi. (475 km.) by rail. Kassala (343 mi. [552 km.]) and the Gezira are directly served by a branch line and a new road to Kassala and Khartoum was opened in 1962. There is an airport with regular services to Khartoum, Atbara, Cairo, Jidda, and Beirut.

Port Sudan has a hot, near-desert climate. Fresh water is piped from Khawr (Khor) Arba'at in the Red Sea Hills, and there are salt-evaporating pans and irrigated market gardens. Among imports cotton textiles have been displaced from first importance by machinery, vehicles, fuel oil, and building materials—commodities vital to development in the republic. The chief exports are cotton, gum, oilseeds, peanuts, hides and skins, and senna.

(M. T. P.)

PORT TALBOT, a municipal borough in the Aberavon parliamentary division of Glamorgan, Wales, on the Avon (Afon) near its mouth in Swansea Bay, 31 mi. (50 km.) WNW of Cardiff by road. Pop. (1961) 51,322. Area 36.6 sq.mi. (95 sq.km.). Port Talbot docks were opened in 1837 and enlarged in 1898 when, after the coming of the railways, coal from the Afon valley was carried by rail for export from the docks. With the passing of the Railways Act in 1921, the Great Western Railway Company took over the docks, and Port Talbot became one of the south Wales chain of ports for coal from the Rhondda and other valleys. It suffered severely in the depression of the 1930s. The docks are now used for the export of coal and coke, iron and steel, tin plate, etc., and the import of iron ore, timber and other mainly heavy-class goods.

In 1947 the gigantic Abbey steel works at Margam were built by four companies as a reconstruction project for bringing up to date the sheet steel and tin plate industries of south Wales. This led, in turn, to the adaptation of the docks to meet the additional traffic. The steel works are named after Margam Abbey, a Cistercian Foundation of 1147, on which land they are built near the ruins of the abbey and also near Margam Castle and the docks. Margam urban district and Aberavon town were amalgamated in 1921 under the name of Port Talbot.

Besides workers in steel, oxygen, industrial solvents, and on the docks, Port Talbot has a farming community. Two agricultural shows and a horticultural show are held annually as well as open and local shows of the Port Talbot Cage Birds Society. The Aberavon Fair (formerly a flannel fair) is held twice yearly under the 13th-century charter of Hugh le Despenser. On the beach, with its fine stretch of sand, is a pleasure fair near the promenade. On reclaimed marshland to the west of the town the large housing estate of Sandfields was constructed. Open spaces include the Talbot and Vivian Memorial parks, each of 12 ac. (5 ha.).

PORTUGAL, a country of southwestern Europe and a republic since 1910, flanks the western side of the Iberian Peninsula. It has an area of 35,340 sq.mi. (91,530 sq.km.), roughly rectangular in shape, with a breadth varying from 140 mi. (225 km.) in the north to about 70 mi. (113 km.) in southern Alentejo, and a north-south extent of about 360 mi. (579 km.). The Atlantic island groups of the Azores and Madeira (area 1,201 sq.mi. [3,111 sq.km.]) are included within metropolitan Portugal. They had 595,875 inhabitants in 1960 when Portugal proper had 8,255,414. The sea is the horizon from every Portuguese summit, the coast stretching for a distance of about 500 mi. (805 km.). The land frontiers with Spain are either along stretches of the major rivers, the Minho, Douro, Tagus, and Guadiana, or in rugged, sparsely populated mountains.

I. PHYSICAL GEOGRAPHY

1. Structure and Relief.—Relief divides Portugal along the Tagus Valley into a mountainous north and a lowland south. Of the land above 1,300 ft., more than 90% lies to the north of the Tagus, and about 60% of the land below 650 ft. is to the south, providing the fundamental contrast of the country. Seven-tenths of the country belongs to the ancient block of the Meseta, folded in Hercynian times and fractured by the later Tertiary movements. About 40% of the total area consists of hard slates, schists, and granites, which are an essential feature of northern Portugal. The well-marked pattern of the valleys in the northern highlands, guided by the lines of fracture and warping, is also a characteristic. The western appendage of the Central Cordillera, the Serra da Estrêla, 6,532 ft. (1,991 m.), has the highest relief, forming the backbone of Beira. The next highest mountains frame the Galician border:

Serra do Gerez (4,944 ft.), Larouco, 5,003 ft. (1,525 m.), and Nogueira near Braganza or Bragança (4,324 ft.). North of the Douro, the ancient block touches the seacoast along a well-defined line of fracture, permitting only a narrow coastal plain. Between the Douro and the Mondego, the mountain blocks of Montemuro (4,534 ft.) and the Serra do Caramulo (3,514 ft.) separate the high plateaus of Beira from the broad coastal plain and Ria de Aveiro. To the south, the Mesozoic limestones and sandstones are folded into rolling, hilly relief in Estremadura and part of Ribatejo.

Most of southern Portugal represents a stable ancient block, gently lowered so that the Tertiary surfaces of the southwestern Meseta continue uninterrupted across the monotonous schistose and granitic plains of lower Alentejo. Even the higher plateaus of upper Alentejo (São Mamede, 3,363 ft.), a continuation of the mountains of Toledo, and the Caldeirão (1,893 ft.), the extension of the Sierra Morena, preserve the surface. To the north and west the lower Tagus and Sado represent faulted troughs infilled with Tertiary and Quaternary sediments. The folded hills of Arrábida, 1,644 ft. (501 m.) north of the lower Sado and the more extensive scarps and hills behind the Algarve coast comprise Mesozoic limestones and sandstones. The highest relief of Algarve is in the Monchique (2,959 ft.), a dissected syenite massif.

All the main rivers of Portugal flow from Spain over the edge of the Meseta in a series of defiles and gorges. Consequently none of them is navigable between the two countries (with the possible exceptions of the lower Minho and Guadiana) and Portugal and Spain have turned their backs on each other, though several rivers do have local traffic, notably the Douro. Sandbars at the mouths of many rivers are further disadvantages, so that Lisbon is the only obvious choice for a large port. The changing fortunes of the ports of Algarve have reflected the variations of silting along the coast, while the past history of ports in Beira Litoral has been similar. It is somewhat paradoxical that much of the Portuguese coast south of the Mondego should be relatively sparsely populated when the sea has played such an important role in the country's history and there is an average of one mile of coast for every 68 sq.mi. of territory.

2. Climate.—The extreme southwesterly position of Portugal in Europe explains its mild, moist winters and its relatively equable and dry summers. Its position through the latitudes 37° to 42° N gives it transitional features between west temperate and Mediterranean conditions. In winter the northern half of Portugal is dominated by the polar front, and in summer the Azores high-pressure system advances northward over the country. In January there is a gentler gradient of sea level temperature, averaging from 11° C (52° F) in the southwest to about 9° (48°-49°) in the northeast. Severe cold is usually associated with the incursion of high-pressure conditions from the Spanish Meseta or from Siberian anticyclones. The highest mountains of Serra da Estrêla have less than 7° (45°) and snow lies on the mountain summits for several months between November and April; but there is no snow line. In summer the oceanic influence is marked; the fact that no part of the interior is more than 134 mi. from the sea is significant. In July the isotherms therefore run north-south, with a steep thermal gradient which rises from 18° (64°) on the west coast, to 2° (80°) or more along the Spanish frontier. Sea breezes at evening temper the summer heat of the coastal zone; e.g., the *noitada* at Lisbon.

Northern Portugal receives considerable rainfall and everywhere on the coast the humidity is relatively high for the latitude. Near the Galician frontier summer drought is not pronounced, but toward the northeast, and especially south of the Tagus, the intensity of summer drought is increased; Oporto (Porto) has a mean annual rainfall of 45 in., falling within 137 rain days; Lisbon 24 in. in 99 days; Lagos 15 in. in 90 days. Relief too plays its role and the Serra da Estrêla has over 110 in., with comparable precipitation in the mountains of the northwest. The leeward position of Trás-os-Montes and the Douro Valley explains partly their lower rainfall of 30-40 in. in 90-130 rain days.

3. Vegetation.—Portugal has been deservedly called "the Garden of Europe." It has more than 2,700 plant species and 53% of

PHYSICAL FEATURES, CITIES, AND GEOGRAPHICAL REGIONS OF PORTUGAL

of the Serra de Arrábida, the alpine flora of Serra da Estrêla, and the numerous exotics of Sintra.

4. Animal Life.—The fauna of Portugal closely resembles that of Spain (*q.v.*). It is largely an admixture of central European and North African types but there are some species indigenous to the Iberian Peninsula that probably originated in earlier geological times. Apart from wild goats, wild boars, and deer found in the mountains, there no longer exist any of the larger wild animals. Probably the last bear was shot in the Serra do Gerez in 1650. Wolves are still found in the remoter parts of the Serra da Estrêla and the lynx in the cistus scrub of Alentejo, while the fox, rabbit, and the Iberian hare are ubiquitous.

There are fewer reptiles than in Spain, but one species of snake (*Pelias berus*) is dangerously poisonous. There are numerous species of grass snake. The chameleon is rare, but it occurs in Algarve, and the amphibian salamander is found occasionally in the mountains. A genus peculiar to the Iberian Peninsula is the slug *Geomalacus*; the spotted variety *G. maculosus* is limited to Portugal and a very restricted area near the Kenmare River in southwest Ireland.

Fish are plentiful, especially the young pilchard (sardine) which comprises over one-third by weight of the total landed, and tunny fishing is important from the ports of Algarve. Crustacea are common on the northern rocky coasts, and there are extensive oyster beds in the Ria de Aveiro, the estuaries of the Tagus, and especially the Sado.

As in Spain, there is a rich bird life, since the peninsula lies on the winter migration routes of western and central European species. In spring, north African species fly northward along the Portuguese coast. Very few birds, however, remain throughout the year in Portugal. Indigenous species include a blue magpie, particular varieties of a cuckoo, an owl, and a red partridge. Vultures, kestrels, and eagles nest on the rocky heights, while the stork (protected by special legislation), snipe, and quail are common in the coastal marshes.

Much of the wild life was destroyed during the Middle Ages when the king and the nobility created extensive preserves (*condadas*). Modern conditions controlling hunting and shooting are based on the Civil Code of July 1, 1867, but some municipalities also have local restrictions. The close season is roughly between Feb. 15 and Sept. 1, though quail shooting begins on Aug. 1.

II. GEOGRAPHICAL REGIONS

Since the Middle Ages six provinces have clearly divided the country: Minho, Trás-os-Montes, Beira, Estremadura, Alentejo, and Algarve (*qq.v.*). These were divided in 1833 into 17 districts, each named after its chief town, with the district of Setúbal subsequently added. In 1933, 11 new provinces were created on a geographical and economic basis. Provincial names survive for geographical designation but the 18 districts of continental Portugal are now the largest administrative subdivisions.

The landscapes of Portugal are more diverse than these administrative regions would suggest. The granite country of the Minho with its misty blue skies, green bocage, and intense polyculture, the terraced vineyards of the Douro Valley, the treeless plateaus and nucleated villages of Trás-os-Montes, the mountain splendour of Beira, the "dutch" landscape of the Ria de Aveiro the orchards and vineyards of Estremadura, the lush pastures of the Tagus in Ribatejo, the monotonous cereal lands of Alentejo, and the dusty orchards of Algarve are only a few of its varied vignettes.

In the past the contrasts between the lands north and south of the Tagus were sharper than they now appear. The spread of the olive and vine, the rapid development since the 16th century of the maize (corn) plant, and the advance of the pine forests, have tended to obliterate some of the native contrasts between the Atlantic and Mediterranean facades of Portugal. Further transformation has taken place since the beginning of the 20th century, with the colonization of waste in Alentejo for cereal lands, reducing to some extent the contrast between the densely settled lands of the north, and the relatively sparse population of the southern half of Portugal. Only the northeast, remote and poor, has preserved archaic and traditional forms of life. (J. M. Ho.)

all those found in Spain, which is so much more extensive in area. The chief characteristic is the mingling of Atlantic deciduous flora with Mediterranean and African evergreens; about two-thirds are European species, about one-third Iberian and African. North of the Mondego Valley the European and Mediterranean species represent 57% and 26% respectively. Between the Mondego and Tagus these percentages are 38 and 42, and it is there that the mingling is most marked, especially in the lovely woodlands of Sintra and Serra do Bussaco. The soil conditions there are influential, for on the calcareous soils the Mediterranean species increase to 56%, whereas on the siliceous soils they are scarcely 36%. Two species of pine (*Pinus pinaster* and *P. pinea*) and three species of oak (*Quercus robur*, *Q. toza*, and *Q. lusitanica*) predominate in the northern half of Portugal, with notable concentrations of maritime pine in the coastal lands and the Toza oak (*Q. bellota*), linden, elm, and poplar are widespread. South of the Tagus there are four significant concentrations of tree species. In western Alentejo the cork oak estates predominate, mixed with evergreen oak to the east, and umbrella pines in the Sado basin. Lower Algarve is renowned for its groves of carobs, almonds, and figs. The olive, once concentrated in the south, is now widespread, with significant extent in Algarve, central Portugal, and the Douro Valley. The Australian eucalyptus flourishes in the ill-drained valleys of the Tagus and Sado. Noted specialized flora are the aquatic plants of the Aveiro lagoons, the Mediterranean species

III. THE PEOPLE

Although western Iberia has been occupied for a long time, relatively few remains of Paleolithic man have been found. Neolithic and Bronze Age discoveries are commoner, among them many dolmens. Some of the earliest permanent settlements were the northern *citánias* or *castros*, hill villages first built by Neolithic farmers who began clearing the forests of western Iberia. Incoming peoples, Phoenicians, Greeks, and Celts, intermingled with the settled inhabitants, and celticized natives occupied the fortified *citánias*. For 200 years these were centres of resistance against Roman legions. Subsequently the Romans, Suebi (Suevi), Visigoths, Moors, and Jews exerted various influences over the territory which in the 13th century acquired the frontiers of modern Portugal.

1. Racial Types.—Portugal's situation at the western extremity of Europe made it a gathering ground for invaders by land, and its long coastline invited settlement by seafarers. Although formed of different elements, the population of Portugal is one of the most homogeneous in Europe, and has physical characteristics which are common to circum-Mediterranean peoples. Most Portuguese are of slightly lower than average stature (the average height of the adult male is 1,640 mm. [5 ft. 5 in.]), have brown eyes, dark wavy hair, and a pallid or brunet skin. The average cephalic index is 76–78.

2. Religion.—The largest part of the Portuguese population traditionally follows the Roman Catholic Church. Though freedom of worship is permitted, followers of other creeds are few, including about 3,000 Jews. The country is divided into three ecclesiastical provinces, Lisbon, Braga, and Évora. The archbishop of Lisbon is the metropolitan for all Portugal, with the title of patriarch, and is vested with the dignity of cardinal. The church is separated from the state and a concordat regulates the relations of Portugal with the Holy See.

3. Language.—Portuguese is one of the richest Romance languages and has a greater variety of sounds than Spanish. Although rooted in Latin, it has a few words of Germanic and Semitic origin introduced after the decline of the Roman power, when the Iberian Peninsula, or part of it, was for some centuries under the domain of the Visigoths and the Moors. The language is remarkably uniform throughout the country, including the Azores and Madeira. Differences in the speech of the provinces are mainly phonetic; differences in vocabulary, where they exist, are minor and limited to a confined area, so that there is no question of any different dialects. Only at Miranda do Douro, in the northeastern corner of Portugal, is there a true dialect, which is now indeed recognized as a linguistic curiosity. Portuguese is also spoken in the overseas provinces and in Brazil, and the literary language is there preserved in its purity. (See PORTUGUESE LANGUAGE.)

4. Customs and Culture.—In spite of certain affinities with the neighbouring Spaniards, the Portuguese have their own distinctive way of life. The geographical variety of the country has evoked different responses but there is less regionalism than in Spain. Dancing and singing play a prominent part in the life of the people. Almost every village has its own *terreiro* or dancing floor of beaten earth. Many popular dances are lively, and the *verdegaio*, *cana verde*, *malhão*, *vira*, *chula*, *fandango*, *corridinho*, *bailarico*, etc., may be seen at *romarias* or pilgrimages which combine religion with the attractions of a fair. Each region has its own style of dances and songs; most traditional songs are of a slower rhythm than those in Spain. Small accordions are often used to accompany dances and Portuguese guitars accompany the *fado* and other songs. Fiddles, drums, and triangles are popular, and bagpipes are played in some regions.

Bullfighting is a popular sport which is conducted differently from bullfights in Spain. The bulls are not killed and often their horns are sheathed to prevent injury to the horses.

Differences in environment cause variety in styles of building and dress, some distinctive garments being the *capucha*, a hooded cape worn in mountain areas, and the *palhoças*, a rain cape made of reeds and worn in the Douro Valley area.

The staple diet is one of fish (mainly sardines and dried cod), vegetables, and fruit. Meat is seldom eaten, although village

farmers each keep a few pigs which are killed for special occasions. In general wine is consumed sparingly. (J. R. D. S.-J.; X.)

IV. HISTORY

Portugal has existed as an independent state since the 12th century A.D., when it finally detached itself from the kingdom of León. Possibly even as much as two centuries earlier there was a county of Portugal, covering an area roughly equivalent to the northern half of the modern state; but before this the territory now called Portugal had no consecutive political history independent of that of Spain (*q.v.*), nor, indeed, a distinctive name.

A. ROME AND THE BARBARIAN INVASIONS

When, after the Second Punic War (218–201 B.C.), Rome replaced Carthage as the imperial power in the Iberian Peninsula, the territory which was to become northern Portugal was occupied by the Lusitani, tribes probably Iberian in origin although their language had some Celtic characteristics. Polybius (2nd century B.C.) and Strabo (1st century B.C.) describe them as a nimble warlike people, who preferred raiding to agriculture. Their resistance to the Romans intensified after a large number were massacred or enslaved by the treachery of the praetor Servius Sulpicius Galba (150 B.C.). Under their leader Viriatus they won victories as far afield as Andalusia. Viriatus was, however, assassinated in 139 B.C. and Decimus Junius Brutus penetrated (138–136) into the extreme northwest of the peninsula, enforcing a general pacification. The name Lusitania was given to the westernmost of the three provinces into which Marcus Vipsanius Agrippa divided the peninsula (27 B.C.). This province included most of modern Portugal but also spread eastward, its capital being at Merida in Spain.

In the year A.D. 409 Vandals, Alani, and Suebi (*q.v.*) entered Spain. Lusitania was briefly occupied by the Alani and later by the Suebi. But the Visigoths (*see* GOTHs) who arrived in 414 later pushed them back to the northwest corner of the peninsula, which eventually (585) came entirely under Visigothic rule.

Christianity had reached Lusitania by the end of the 3rd century, when bishops from Évora and two other Lusitanian sees attended a council (*c.* 300) at Illiberi (Elvira, near Granada) and the persecutions ordered by Diocletian produced martyrs at Merida and, according to tradition, in Lisbon, as well as in other areas. Visigothic influence later made the whole peninsula officially Arian until the conversion to Catholicism of the Visigothic king Recared in 586. From this time until the Muslim invasion of 711 Portuguese history is indistinguishable from the little that is known of the Visigothic kingdom. With the fall of this power the whole of Portugal passed under Muslim rule; but there was little Arab or Berber settlement in the north, and by the late 8th century the expansion of the Christian kingdoms of Asturias and León destroyed Muslim power north of the Douro River.

B. THE COUNTY AND THE KINGDOM (TO 1383)

It was in this early period of reconquest and resettlement that the phrase *terra portucalis* was first used. Derived from the name of a Roman settlement on the shore of the Douro, *Portus Cale* it came to be applied to a wider area from the Douro to the Galician frontier, the Minho River. This area became in the 10th century a hereditary county, when the first known governors were Dona Mumadona Dias and her husband Hermenegildo Gonçalves. Half a century later a member of this family was tutor and later father-in-law to Alfonso V of León, but under Ferdinand I the Great of Castile and León it appears to have lost its influence. In 1064 Ferdinand carried the reconquest down to the Mondego River, capturing Coimbra and appointing a governor there.

Under Alfonso VI of León (1065–1109) and Castile (1072–1109), the county of Portugal reappears and incorporates the district of Coimbra, to form the domain of Alfonso's illegitimate daughter Teresa and her husband Henry, brother of Duke Eudes (Odo) I of Burgundy. From 1095, therefore, Count Henry and Queen Teresa, as she sometimes called herself, governed Portugal and held the Coimbra frontier as vassals of León. On the death of Alfonso VI, when León passed to his legitimate daughter Urraca

Henry attempted to invade her domains, but had achieved little success when he died in 1112. His son Afonso I, called Henriques, was an infant; and his widow, actuated by jealousy of her half sister, vainly endeavoured to intervene in the affairs of León and Galicia. Her association with her Galician favourite Fernão Peres, count of Trava, lost her the esteem of the Portuguese nobility and clergy. In 1128, after she had again embroiled Portugal in a futile conflict with León, supporters of her young son defeated her followers in the battle of São Mamede, and she and Fernão Peres were exiled.

Already in 1124 Urraca's son Alfonso VII had armed himself knight and been declared king of León. His cousin Afonso Henriques similarly armed himself knight (a privilege usually confined to kings) a year later and, on the banishment of his mother, became count of Portugal. During his first years Afonso Henriques fought vigorously on all frontiers, invading Galicia in the north and repelling the Muslims in the south. On July 25, 1139, he defeated the Muslims in the Battle of Ourique (probably not the modern town of the same name). Soon after, he assumed the royal style (1140). In 1143, as a result of his campaigns and of negotiations with his cousin, his independence was admitted by León, and he placed Portugal under the direct protection of the Holy See, promising to pay an annual tribute. In March 1147 he carried the frontiers of Christian Portugal south to the Tagus with the capture of Santarém, and the assistance of a band of English, French, Flemish, and German crusaders bound for Palestine enabled him to undertake the siege of Lisbon, which fell in October 1147. An English crusader, Gilbert of Hastings, became the first bishop of the restored see of Lisbon.

In Afonso's later years, from 1179 to 1184, the Muslims, stifened by the Almohads (*q.v.*) from Morocco, regained some ground in the south but failed to take Santarém or Lisbon; and when he died on Dec. 6, 1185, Afonso had not only gained Portugal's independence but doubled its territory. The military orders, especially the Templars, but also those of Santiago (founded c. 1170) and Calatrava (c. 1156) and later the Hospitallers, assisted in the defense and resettlement of the areas regained from the Muslims, and the Cistercians introduced good agriculture and architecture into central Portugal, making their headquarters at Alcobaça.

Although Afonso Henriques began to grant charters to new settlements, it was his son Sancho I (1185–1211) who enfranchised many municipalities (*concelhos*), especially in eastern and central Portugal. The privileges of these communities were embodied in charters (*forais*), which attracted settlers from the more feudal north. Even Muslims were enfranchised, though on the other hand many of them were enslaved. Assisted by passing crusaders, Sancho captured Silves in Algarve (1189); but in 1190 an Almohad army from Africa advanced to the Tagus and, although Lisbon, Santarém, and Tomar stood firm, the Muslims recovered Silves in 1191 together with most of the land south of the Tagus. In his later years Sancho was involved in a quarrel with Pope Innocent III over the payment of tribute due to the Holy See, and with the bishop of Oporto, who received Innocent's support. But peace was made before his death, and it was left to his son Afonso II, the Fat (1211–23), to endeavour to strengthen the throne at the expense of the church.

Though Afonso II was an unwarlike king, his followers were beside the Castilians at the great Christian victory of Las Navas de Tolosa in 1212 and, again assisted by crusaders, recovered Alcácer do Sal in 1217. Meanwhile Afonso repudiated the bequests of large estates made by his father to his brothers and accepted those to his sisters only after a war with León and in a form settled by the pope which recognized Afonso's sovereignty. In the first year of his reign, Afonso called a meeting of the *Cortes* at Coimbra, to which the nobility and prelates were summoned (representatives of the commoners were not to appear until 1254). Both estates obtained important concessions; in fact the position of the church and the orders was now so strong that Afonso II and his successors were involved in recurrent conflicts with Rome. Afonso himself instituted (from 1220) *inquirições* or royal commissions to investigate the nature of holdings and recover what ever had been illegally taken from the crown. In his last years

Afonso quarreled with the archbishop of Braga who was supported by Pope Honorius III, defied the papacy, and was excommunicated.

Little is known of the reign of his son Sancho II (1223–45), but the reconquest of Alentejo was now completed and much of Algarve was reduced. On his accession, Sancho found the church in full ascendancy as a result of the agreement made before his father's death. Conflicting reports exist of Sancho's own government, but in his later years the kingdom seems to have slipped into anarchy. At all events his younger brother Afonso, who had become count of Boulogne by his marriage (1235) with Matilda, daughter of Count Raynald I of Dammartin, was granted a papal commission (1245) to take over the government, and Sancho was ordered to be deposed by papal bull. When Afonso reached Lisbon (late 1245 or early 1246), he received the support of the church and of the inhabitants of Lisbon and other towns. After a civil war lasting two years, Sancho II retired to Toledo, dying there in January 1248.

On his arrival the count of Boulogne had already declared himself king as Afonso III, and the death of Sancho without issue gave his usurpation the mantle of legality. He brought together the divided kingdom, completed the reconquest of Algarve, transferred the capital from Coimbra to Lisbon, and, fortified by the support of the towns, summoned the *Cortes* at Leiria at which for the first time commoners representing the municipalities made their appearance (1254). His conquest of Algarve aroused the jealousy of Castile. Two campaigns were fought (1250 and 1252), Afonso probably being worsted, and peace was made by means of a marriage pact. Although still the husband of Matilda of Boulogne, Afonso married Beatriz, illegitimate daughter of Alfonso X of Castile, holding the disputed territory of Algarve as a fief of Castile until such time as the eldest son of the marriage should reach the age of seven, when Algarve was to return to Portugal. This marriage led to a dispute with the Holy See, in which Afonso was placed under an interdict. Despite his early connection with Rome, Afonso refused to give way, and in 1263 the bigamous marriage was legalized and his eldest son, Diniz (Denis), legitimized. Shortly afterward, Afonso launched *inquirições*, as a result of which the church was deprived of much property. The prelates protested and most of them left the country. Although Afonso was excommunicated and threatened with deposition, he defied the church until shortly before his death early in 1279.

The achievements of Afonso's reign—the completion of the reconquest, the assertion of the royal power before the church, and the incorporation of the commoners in the *Cortes*—indicate important institutional advances. Under his son Diniz (1279–1325), Portugal was to come into closer touch with Western Europe and to acquire a university, the elements of a national literature, and a navy. The chartering of fairs and the increased use of minted money bear witness to the growth of commerce, and the planting of pine forests to hold back the sand dunes near Leiria illustrates Diniz' concern for shipbuilding and agriculture. In 1317 Diniz engaged a Genoese admiral, Emmanuele di Pezagna (Manoel Pessanha), to build up his navy, having already adopted various measures to stimulate foreign trade. He founded the University of Coimbra (at first in Lisbon) in 1290 and was both a poet and patron of literature. Yet he was especially famed as the "farmer king" (*rei lavrador*) for his interest in the land.

Despite his attachment to the arts of peace, Portugal was several times involved in strife during the reign of Diniz. In 1297 the Treaty of Alcañices with Castile confirmed Portugal's possession of Algarve and provided for an alliance between Portugal and Castile. In the later years of his reign, his son, the future Afonso IV, rebelled more than once, being persuaded to submit by the influence of his mother Isabella, daughter of Peter III of Aragon. This remarkable woman, later canonized as St. Elizabeth of Portugal and popularly known as *a Rainha-Santa*, successfully exercised her influence in favour of peace on several occasions.

Afonso IV (1325–57) was also involved in various disputes with Castile. Isabella, who had retired to the Convent of Santa Clara at Coimbra, continued to intervene in favour of peace; but on her death in 1336 war broke out, and terms were not made till 1340, when Afonso himself with a Portuguese army joined Alfonso XI of

Castile in the great victory over the Muslims on the Salado River in Andalusia. Afonso's son Pedro was married (1336) to Constanza (d. 1345), daughter of the Castilian infante Juan Manuel de Peñafiel, but soon after the marriage he fell in love with one of her ladies, Inês de Castro (*q.v.*), by whom he had several children. Afonso was persuaded to countenance the assassination of Inês in 1355, and one of Pedro I's earliest acts on his accession was to take vengeance on her murderers. During his short reign (1357-67), Pedro devoted himself to the dispensation of justice; his judgments, which he executed himself, were severe and often violent, and his iron rule was tempered only by fits of revelling.

Pedro's son by Constanza, Ferdinand (1367-83), inherited a wealthy throne almost free of external entanglements; but the dispute between Pedro the Cruel and Henry of Trastámara (later Henry II) for the Castilian throne was raging, and on the murder (1369) of the former, several Castilian towns offered to Ferdinand their allegiance, which he was unwise enough to accept. Henry II duly invaded Portugal in 1369, and by the Peace of Alcoutim (1371) Ferdinand was constrained to renounce his claim and to promise to marry Henry's daughter. However, he instead took a Portuguese, Leonor Teles, although she was already married and in spite of the protests of the commoners of Lisbon. He also made alliance (1372) with John of Gaunt, duke of Lancaster, who had married the elder daughter of Pedro the Cruel and claimed the Castilian throne. In 1372 Ferdinand provoked Henry II, who invaded Portugal and besieged Lisbon. Unable to resist, Ferdinand was forced to repudiate his alliance with John of Gaunt and to act as an ally of Castile, surrendering various castles and persons as hostages. It was only on the death (1379) of Henry that Ferdinand dared openly to challenge Castile again. In 1380 the English connection was resumed, and in the following year John of Gaunt's brother, Edmund of Langley, earl of Cambridge (afterward duke of York), took a force to Portugal for the invasion of Castile and betrothed his son Edward to Ferdinand's only legitimate child, Beatriz. In mid-campaign Ferdinand came to terms with the enemy (August 1382), agreeing to marry Beatriz to a Castilian prince. She did in effect become the wife of John I of Castile, and when Ferdinand died, prematurely decrepit, Leonor Teles became regent and Castile claimed the Portuguese crown.

Leonor had long been the paramour of the Galician João Fernandes Andeiro (*q.v.*), count of Ourém, who had intrigued with both England and Castile and whose influence was much resented by Portuguese patriots. Opponents of Castile chose as their leader an illegitimate son of Pedro, John, mestre de Avis, who killed Ourém (December 1383) and, being assured of the support of the populace of Lisbon, assumed the title of defender of the realm. The regent fled to Alenquer and thence to Santarém, and the king of Castile came to her aid, soon, however, relegating her to a Spanish convent. Lisbon was besieged for five months (1384), but an outbreak of plague obliged the Castilians to retire.

C. THE HOUSE OF AVIS, 1383-1580

The legitimate male line of Henry of Burgundy ended at Ferdinand's death, and when the *Cortes* met at Coimbra (March-April 1385) John was declared king and became the founder of a new dynasty. This result was not unopposed, for many of the nobility and clergy still considered the queen of Castile the rightful heiress; but popular feeling was strong, and John I had valuable allies in Nuno Álvares Pereira (*q.v.*), "the Holy Constable," his military champion, and João das Ragras, his chancellor and jurist.

A number of towns and castles still held out for Castile when in August 1385 John I of Castile and a considerable army made their appearance in central Portugal. Although much outnumbered, the Portuguese won the great Battle of Aljubarrota (Aug. 14, 1385) in which the Castilian chivalry was dispersed and John of Castile himself barely escaped. The victory, followed by secondary successes won by Nuno Álvares, assured John I of his kingdom and made him a desirable ally. A small force of English archers had been present at Aljubarrota. Now the Treaty of Windsor (May 9, 1386) raised the Anglo-Portuguese connection to the status of a firm, binding, and permanent alliance between the two crowns. John of Gaunt duly went to the peninsula (July

1386) and attempted an invasion of Castile in conjunction with John I. This was not successful, but the Portuguese king married Gaunt's daughter Philippa of Lancaster (1387), who introduced various English usages into Portugal and became the mother of five sons and one daughter, the *íncिता geração*. The truce arranged with Castile in 1387 was prolonged at intervals until peace was finally concluded in 1411.

The victory of John of Avis may be regarded as a victory of the national spirit against the feudal attachment to established order. As much of the older nobility had adhered to Castile, John rewarded his followers at their and at the crown's expense. Meanwhile commerce prospered, and the marriage of John's daughter Isabella to Philip the Good of Burgundy was to be followed by the growth of close trading relations between Portugal and Philip's County of Flanders. With the conclusion of peace with Castile, John found an outlet for the activities of his frontiersmen and of his own sons in the conquest of Ceuta (1415), from which may be dated the great age of Portuguese expansion.

During the short reign of John's eldest son Edward (Duarte), (1433-38), an unsuccessful attempt was made to conquer Tangier in 1437 by Prince Henry the Navigator and his younger brother Ferdinand, who was captured by the Moors and died, still unransomed, in 1443. On Edward's death his son Afonso V was still a child, and his brother Pedro, duke of Coimbra, had himself made regent (1440) instead of the widow, Leonor of Aragon. But Pedro's own regency was later challenged by the powerful Braganza family, descended from Afonso, illegitimate son of John of Avis and Beatriz, daughter of Nuno Álvares Pereira. This family continued to set the young king against his uncle, who was forced to resign the regency, driven to take up arms, and killed at Alfarrobeira (May 1449). Afonso V (1438-81) proved unable to resist the demands of the Braganzas, who now came to own about a third of all Portugal. Having married Joan, daughter of Henry IV of Castile, Afonso laid claim to the Castilian throne and became involved in a lengthy struggle with Ferdinand and Isabella in the region of Zamora and Toro, where he was defeated in 1476. He then sailed to France to entreat the aid of Louis XI, in which he failed, and on his return concluded with Castile the Treaty of Alcáçovas (1479), abandoning the claims of his wife Joan. Afonso never recovered from this reverse, and during his last years his son John administered the kingdom.

John II (1481-95) was as cautious, firm, and jealous of the royal power as his father had been openhanded and negligent. At the first *Cortes* of his reign he exacted a detailed oath of homage which displeased his greatest vassals. A suspicion of conspiracy enabled him to arrest Fernando II, duke of Braganza, and many of his followers; the duke was sentenced to death and executed (1483) at Évora, and John himself stabbed James (Diogo), duke of Viseu (1484). As well as attacking the power of the nobility John lessened the effects of the unfavourable treaty with Castile. Calculating and resolute, he received the epithet of "the Perfect."

John II was predeceased by his legitimate son and therefore succeeded by his cousin, the duke of Beja, as Manuel I (1495-1521), known as "the Fortunate." Manuel, who assumed the title of "lord of the conquest, navigation, and commerce of India, Ethiopia, Arabia, and Persia," inherited, because of the work of John II, a firmly established autocratic monarchy and a rapidly expanding overseas empire. Drawn toward Spain by the common need to defend their overseas interests as defined by the Treaty of Tordesillas (1494; *q.v.*), Manuel nourished the hope of joining the whole peninsula under the house of Avis; he married Isabella, eldest daughter of Ferdinand and Isabella, who, however, died (1498) in giving birth to a son, Miguel da Paz. This child was recognized as heir to Portugal, Castile, and Aragon, but died in infancy. Manuel then married Isabella's sister Maria (d. 1517) and thirdly Eleanor, sister of the emperor Charles V.

As a condition of the marriage with Isabella, Manuel was required to "purify" Portugal of Jews. John II had admitted many Jewish refugees expelled from Spain (1492) and had taxed them heavily, but was also to supply ships for them to leave Portugal within eight months. This was not done, and Manuel now ordered all Jews to leave by October 1497. On their assembly in Lisbon,

every effort was made to secure their conversion by promises or by force. Some who resisted were allowed to go, but the rest were "converted" under promise that no inquiry should be made into their beliefs for 20 years. As "Christians" they could not be forced to emigrate, and they were indeed prohibited from leaving Portugal. In April 1506 a large number of these "new Christians," or *marranos*, were massacred in Lisbon during a riot, but Manuel afterward protected them and allowed many to emigrate to Holland, where their experience of Portuguese trade was put at the service of the Dutch.

If Manuel failed to realize his dream of ruling Spain, his son John III (1521-57) lacked the power to resist Castilian influence. A pious, dull man, he was ruled by his wife, Queen Catherine, sister of the emperor Charles V, and encouraged the installation of the Inquisition (1536); the first auto-da-fé was held in 1540. The Society of Jesus, established in 1540, soon controlled education in Portugal. In 1529 the settlement by the Treaty of Saragossa of a dispute over the possession of the Moluccas removed an obstacle to Portuguese-Spanish understanding, and the line of Tordesillas was matched by a similar line in the Pacific; all the countries in the New World were in theory divided between Spain and Portugal, while the Reformation (as well as the discoveries) had come between the latter and its English ally.

John III was succeeded by his grandson Sebastian (1557-78), then a child of three. As a boy Sebastian became obsessed with the idea of a crusade against Morocco. Fanatically religious, he had no doubts of his own powers and listened only to flatterers. He visited Ceuta and Tangier in 1574 and began in 1576 to prepare a large expedition against Larache (El Araish); this departed in June 1578 and on Aug. 4 was utterly destroyed by the Moors at the Battle of the Three Kings near Alcazarquivir. Sebastian himself was killed, 8,000 of his men are said to have died and 15,000 were captured. Only a handful escaped.

Sebastian was succeeded by his great-uncle, Cardinal Henry (1578-80), a brother of John III. His age and celibacy made it certain that the Portuguese throne would soon pass from the direct line of Avis. Philip II of Spain, nephew of John III and husband (by his first marriage) of John's daughter Maria, had already made his preparations and, on the death of the cardinal-king (Jan. 31, 1580), summoned the authorities to obey him. An army under the great duke de Alba (see ALBA, FERNANDO ÁLVAREZ DE TOLEDO, duke de) entered Portugal in 1580, the resistance of Antonio the prior of Crato (illegitimate son of John III's brother Luís), acclaimed Antonio I at Santarém, collapsed, and Philip II of Spain became Philip I of Portugal (1580-98). The claims of the duchess of Braganza (Catherine, daughter of John's brother Edward) were disregarded. (H. V. L.; X.)

D. MEDIEVAL SOCIAL AND ECONOMIC DEVELOPMENT

Medieval Portugal comprised regions of considerable diversity. In the north the old aristocracy of Leónese descent owned large estates worked mainly by serfs. In the south, the territory of the Reconquest, there were many towns, often separated by districts almost barren and depopulated. The initiative in settling these areas was taken by the Cistercian monks who had reached Portugal by 1143; later kings such as Sancho I and Afonso III established *concelhos* (municipalities), granting to them by the issue of *forais* (charters) many privileges designed to attract population. Tax concessions were often given and freedom was promised to serfs or to Christian captives after a year's residence. But in the south the *concelhos* were burdened with defense duties, the *cavalleiros-vilãos* (villein knights) being obliged to horse and arm themselves and the *peões* or less substantial men to serve as foot soldiers in defense of the country and perhaps also on a *fossado* (raid) into Muslim territory.

At court the king was advised by his *curia regis* (court or council), comprising the *major domus curiae*, the head of the administration, the military chief or *signifer*, the *dapifer curiae* (steward of the household), the chancellor (an official whose origins in Portugal were Burgundian rather than Visigothic), and any members of the greater aristocracy, the *ricos-homens*, who might be at court. This class also comprised the bishops and abbots and

masters of the orders of knighthood; many held private civil or military authority. The lesser nobility were without such rights. Below them came various classes of free commoners, such as the *cavalleiros-vilãos* and the *malados*, men who had commended themselves to protectors. There were numerous serfs and slaves.

By the end of the medieval period several shifts in the social structure had occurred. Many of the old aristocracy lost their position at the advent of the house of Avis and the new nobility, exemplified in the house of Braganza, was often of bureaucratic or ministerial origin. The privileges granted to *concelhos* forced landlords to compete for labour and by the time of Afonso III money payments had largely replaced labour services on the estates. Representatives of the commoners, first attending the *Cortes* in 1254 on behalf of the *concelhos*, took an increasing part in politics. The *Cortes* were very frequently called in the reigns of John I, Duarte, and Afonso V; but the avenues of power had become wider by the 16th century and John III's proposal (1525) to call them only every ten years aroused no opposition. Although the trade guilds were slow in developing, they took some part in determining local taxation in the 13th century. Trade increased, Portuguese merchants having connections with the Low Countries from the time of Afonso Henriques and with England from the early 13th century. A coin shortage in the 13th century and debasements in the late 14th and early 15th centuries caused widespread difficulties and unrest, however. (X.)

E. THE DISCOVERIES AND THE EMPIRE

The idea of expansion into Africa was a logical result of the completion of the Reconquest in the Peninsula, and the conquest of Ceuta in 1415 probably provided the impulse toward further expansion. The simple idea of fighting the Muslims on their own soil was linked with more complicated motives: the search for a Christian ally, Prester John (*q.v.*); the desire to explore in a scientific sense; the hope of finding a way to the rich spice trade of the Indies; and the impulse to spread the Christian faith. These purposes were gradually molded together into a national enterprise, though at first they represented the hopes and aspirations of one man, Prince Henry (see HENRY the Navigator). The third son of John I and Philippa of Lancaster, known rather inaccurately as "the Navigator" (he himself never went farther afield than Tangier), Henry became (1420) master of the Order of Christ, which King Diniz had founded (1319). The resources of the Order were used to draw together skilled geographers and navigators and to equip a series of expeditions that only gradually began to bear fruit.

The date of Prince Henry's earliest expedition is not exactly known, but appears to have been about 1418, when the island of Porto Santo was visited; the first call at Madeira probably dates from 1419. An attempt was made to settle in the Canaries, and between 1427 and 1431 the Azores were visited by Portuguese seamen. Both the Azores and Madeira were then uninhabited, and their colonization proceeded fairly rapidly from c. 1445. Sugar was exported to Europe and gave the islands great economic importance. Meanwhile, Prince Henry's ships were probing the African coast, passing Cape Bojador in 1434 and Rio de Oro (1436). The unsuccessful expedition against Tangier (1437) was followed by a break in the discoveries; but in 1439 Prince Henry was authorized to colonize the Azores, and from 1440 further expeditions equipped with a new and lighter ship, the caravel, reached the Bay of Arguin (1443), Cape Verde (1444), and by Henry's death (1460) had explored the coast as far south as Sierra Leone.

Under Afonso V three military expeditions were sent against Morocco (1458, 1461, and 1471); by the last of them Tangier and Arzila were captured. The African explorations were not entirely neglected, but it remained for John II, with his sharp sense of the national interest, to found a fortress and trading post in the Gulf of Guinea at Elmina (São Jorge da Mina, 1481-82). Diogo Cam (Cão) discovered the mouth of the Congo in 1482 and then advanced to Cape Cross, 200 leagues southward (1486). In 1488 Bartolomeu Dias de Novais at length rounded the Cape of Good Hope and reached the East African coast, and the seaway to India lay open. His return was followed in 1492 with the news that

Christopher Columbus had, as he thought, discovered the Indies by sailing west across the Atlantic. Much as this news must have perturbed the Portuguese, Columbus brought no news of the spices or the cities of the East, and John II ordered the preparation of an expedition to India by way of the Cape of Good Hope, though this sailed only after his death. John also contested the Spanish claim to all lands discovered west of the Atlantic, and by the Treaty of Tordesillas (June 7, 1494) Spain's rights were limited to what lay more than 370 leagues west of the Cape Verde Islands. Thus the territory that was to become Brazil was reserved for Portugal.

The Treaty of Tordesillas had confirmed Portugal's rights to the exploration of Africa and the seaway to India. In July 1497 Vasco da Gama set sail with four ships on the first expedition to India. They reached Calicut (Kozhikode) the following spring, and the survivors put into Lisbon in the autumn of 1499 with specimens of Oriental merchandise. A second fleet was at once prepared under Pedro Álvares Cabral, who touched the Brazilian coast (April 22, 1500) and claimed it for Portugal. One of Cabral's ships, under Diogo Dias, discovered Madagascar in 1500; João da Nova discovered Ascension in the following year, and St. Helena in 1502. Tristão da Cunha sighted the islands named after him in 1506 and went on to explore Madagascar. Meanwhile, trading posts in India had been established by Cabral at Cochin and Calicut (1501) and by João da Nova at Cannanore. In 1502 Vasco da Gama made tributary to Portugal the ruler of Kilwa (Quilwa) in East Africa.

In 1505 Francisco de Almeida arrived as viceroy of India, strengthening the African station at Kilwa and supporting the ruler of Cochin against the *samorin* of Calicut. The control of sea trade now instituted became the chief source of Portuguese wealth in the East. It was assured by the defeat of Muslim naval forces off Diu in 1509. Almeida's successor Afonso de Albuquerque (*q.v.*) conquered Goa (1510), which he made the seat of Portuguese power, and Malacca (1511); sent two expeditions to the Moluccas (1512 and 1514); and captured Ormuz in the Persian Gulf (1515). Soon after Fernão Pires de Andrade reached Canton in China; in 1542 Portuguese merchants were permitted to settle at Liampo (Ningpo), and in 1557 they founded the colony of Macao (Macau).

Albuquerque was responsible for this conception of a system of strong points which secured the trade of the Orient to Portugal for nearly a century. Goa soon became the chief port of western India; Ormuz controlled the Persian Gulf and Malacca the gateway from the Indian Ocean to the South China Sea, while a string of fortified trading posts secured the coast of East Africa, the gulf and the shores of India and Ceylon. Farther east, less fortified settlements were set up with the consent of the native rulers from Bengal to China, and the trade of the principal spice islands was in Portuguese hands. The preservation of the whole system was entrusted to a governor, who sometimes held the rank of viceroy, at Goa; and although Portuguese arms had both triumphs and reverses, their control of the Oriental trade remained substantial, if never complete, until the 17th century, when the Dutch, at war with the joint crown of Portugal and Spain and deprived of their traditional trade with Lisbon, began to seek spices from their source and effectively demolished the Portuguese monopoly. The first "governor" of Angola was appointed in 1574.

F. UNION OF SPAIN AND PORTUGAL, 1580-1640

After Philip II of Spain had occupied Portugal in 1580, the island of Terceira in the Azores held out for Antonio of Crato, who himself sought alliances in England and France. In 1582 a French expedition to establish him in the Azores was defeated, and in 1589 an English attempt upon Lisbon, led by Sir Francis Drake and Sir John Norris, failed dismally. But although Antonio died in Paris in 1595, the true symbol of Portuguese independence was not the prior of Crato but King Sebastian himself. The Portuguese people refused to believe that he was dead and nourished a messianic faith in his reappearance, of which four pretenders sought to avail themselves, the last as late as 1600 and as far afield as Venice.

Meanwhile, Philip arrived in Portugal and was accepted as King Philip I (1580-98) by the *Cortes* held at Tomar (1581). He undertook to preserve Portuguese autonomy, to consider the union

as a personal one like that of Aragon and Castile under Ferdinand and Isabella, to appoint only Portuguese to the administration, to summon *Cortes* frequently and to be accompanied by a Portuguese council in Madrid. These undertakings were, however, neglected by Philip II (III of Spain, 1598-1621) and completely violated by Philip III (IV of Spain, 1621-40). Portuguese resentment against Spanish rule was increased by the failure of these kings to visit Portugal, the appointment of Spaniards to Portuguese offices, the loss of trade consequent on Spain's foreign wars, and the levying of taxation to sustain these wars. The final straw was the conde-duque de Olivares' plan (1640) of using Portuguese troops against the equally discontented Catalans. Two Portuguese insurrections in 1634 and 1637 had failed to attain dangerous proportions, but in 1640 Spain's powers were extended to the utmost by war with France and revolt in Catalonia. Richelieu already had agents in Lisbon, and a leader was found in John, duke of Braganza, a grandson of the duchess Catherine (niece of John III) whose claims had been overridden in 1580 by Philip II of Spain. Taking advantage of the unpopularity of the governor, Margaret of Savoy, duchess of Mantua, and her secretary of state Miguel de Vasconcelos, the leaders of the party of independence carried through a nationalist revolution on Dec. 1, 1640. Vasconcelos was almost the only victim; the Spanish garrisons were driven out; and on Dec. 15 the duke of Braganza was crowned as John IV (1640-56).

G. THE HOUSE OF BRAGANZA, 1640-1910

Although the *Cortes* confirmed the accession of the dynasty of Braganza and John's coronation on Jan. 28, 1641, the success of the new regime was not finally assured till 1668, when Spain at last recognized Portuguese independence. Faced with the threat of a Spanish invasion, John had at once sent missions to the courts of Europe in quest of alliances. France now refused a formal treaty. The Dutch, having seized Brazil, accepted a truce in Europe and proceeded to capture Angola from Portugal. John made a treaty (1642) with Charles I of England, which was made void by Charles' execution (1649). Meanwhile, the Portuguese defeated the Spaniards at Montijo (May 26, 1644) and warded off several invasions. In 1654 they negotiated a treaty with the English Commonwealth, obtaining promises of aid in return for very considerable commercial and other concessions. By a secret article of the Treaty of the Pyrenees (1659) France promised Spain to give no further aid to Portugal, but in 1661 Portugal signed a treaty of alliance with the restored English monarchy. In 1662 Charles II of England married John's daughter Catherine of Braganza and in return for a large dowry, including the cession of Bombay and Tangier, provided arms and men for the war with Spain. Portuguese defense was organized by the German soldier Friedrich Hermann von Schönberg (later duke of Schomberg); in June 1661 Sancho Manuel, count of Vila Flor, defeated Don John of Austria at Ameixial, and in June 1665 von Schönberg won the important victory of Montes Claros. Peace was finally made by the Treaty of Lisbon early in 1668.

On the death of John IV his second son Afonso VI (1656-83) was 13 years of age. Afonso's mother Luisa de Guzmán acted as regent until, in June 1662, he began to rule. Afonso himself was feeble-minded, but the country was capably governed by Luiz de Vasconcelos e Sousa, conde de Castelo Melhor, until 1667. The French princess, Marie Françoise Elisabeth de Savoie-Nemours, who had married Afonso in the previous year, now entered into an intrigue with his more personable brother Pedro (afterward Pedro II). They contrived to dismiss Castelo Melhor and to have Marie Françoise' marriage annulled. She at once married Pedro (1668), who was declared regent. Afonso was imprisoned until his death. During the reign of Pedro II (1683-1706), Portugal recovered from the strain of the Spanish wars and began to feel the effects of the discovery of gold and precious stones in Brazil. The first strike of gold in Minas Gerais took place in 1693, and in the last years of the 17th century considerable wealth was being extracted; however, it was not until 1728 that diamonds were discovered and the wealth of Brazil came to form an appreciable part of the revenue of the Portuguese crown.

1. The 18th and 19th Centuries.—The War of the Spanish

Succession (1701–13) saw Portugal's recent friends, England and France, on opposing sides; and although Pedro sought at first to remain neutral, Portugal joined the Anglo-Austrian Grand Alliance in 1703, by which it afforded a base for the archduke Charles (later the emperor Charles VI) to conduct his war for the Spanish throne. In the same year (Dec. 27) the English envoy, John Methuen, also concluded the treaty which bears his name, by which the exchange of port wine for English woollens became the basis for Anglo-Portuguese trade. Although the treaty of 1654 had secured great privileges for English merchants in Lisbon, neither it nor the treaties of 1642 and 1661 by which the traditional alliance was restored had created trade. This was now done, and by reason of the wealth that soon poured into Lisbon from Brazil, the English merchants gained a commanding position in the trade of Portugal. The political treaties of 1703 proved less fruitful. The Portuguese general, Antonio Luis de Sousa, marquess of Minas, entered Madrid in 1706, but French and Spanish forces were victorious at Almansa (1707), and in 1711 the French admiral René Duguay-Trouin sacked Rio de Janeiro. At the end of the war Portugal made a peace treaty with France (April 1713), but did not conclude peace with Spain until February 1715.

Under Pedro's son John V (1706–50) Portugal attained a degree of prosperity unknown since the restoration. The royal fifth levied on the precious metals and stones of Brazil gave the monarchy an independent source of wealth. The *Cortes*, which had met irregularly since 1640, were no longer summoned, and government was carried out by ministers appointed by the king. John V himself showed little interest in administration, though he did not fail to convert his wealth into papal and other dignities. The archbishop of Lisbon became a patriarch (1716) and Pope Benedict XIV in 1749 gave John the title "his most faithful majesty"; and royal academies, palaces, and libraries were built. But in the second half of the reign the ministers proved inadequate and the kingdom sank into stagnation. However, on John's death his son Joseph (1750–77) appointed as minister Sebastião José de Carvalho e Mello, later conde de Oeiras and marquês de Pombal (*q.v.*), who soon gained a complete ascendancy over the king and endeavoured to replace the stagnant absolutism with a more active type of despotism which, with some qualifications, deserves the epithet "enlightened." His full powers date from his efficient handling of the crisis caused by the disastrous Lisbon earthquake of November 1755; but even before this he had reformed the sugar and diamond trades, set up a national silk industry (1750) and formed one chartered company to control the sardine- and tunny-fishing industry of Algarve and another to trade with northern Brazil. In 1756 he founded the *Junta de Comercio*, a board of trade with powers to limit the privileges enjoyed by the English merchants under the treaties of 1654 and 1661, and set up the General Company for Agriculture and for Wines of Alto Douro to control the port wine trade. Industries for the manufacture of hats (1759), cutlery (1764), and other articles were set up with varying success; the University of Coimbra was reformed (1772), and the royal board of censorship (1768) directed lower education from 1771.

Pombal's methods were arbitrary and his enemies numerous. His reform of the wine industry provoked a riot in Oporto (1757) which was savagely repressed; but his principal victims were the Jesuits, expelled in 1759 from all the Portuguese dominions, and the nobility, in particular José Mascarenhas, duque de Aveiro, and the Távora family, who were accused of an attack on the king (Sept. 3, 1758), condemned, and executed (Jan. 12, 1759).

While Pombal succeeded in modifying the ascendancy of the British merchants in Portugal, he invoked the English alliance in 1762 when Spain, prompted by the renewal of the Bourbon Family Compact Alliance with France, invaded Portugal. The Portuguese Army was reformed by Wilhelm von Schaumburg-Lippe, and an English force was led by James O'Hara, 2nd Baron Tyrrawley, and John Campbell, 4th earl of Loudoun. Peace was signed in February 1763 at Fontainebleau. Only the death of Joseph (Feb. 24, 1777) ended Pombal's regime. After the accession of Joseph's daughter Maria I (1777–1816), who had married his brother, her uncle who became King Pedro III, Pombal resigned (1777) and eventually was condemned on several charges. His successors

restored the Jesuits and made peace with Spain by the Treaty of San Ildefonso (1777).

Maria I suffered from melancholia after the loss of her consort (1786) and eldest son John (1788). In 1792 her mental balance was further disturbed, probably by the news of the French Revolution, and she ceased to reign. Her son, who on her death became John VI (1816–26), then ruled in her name and in 1799 became prince regent. In 1793 Portugal joined England and Spain against France, sending a naval division to assist the English Mediterranean fleet and an army to the Catalan front. The Peace of Basel (July 1795), by which Spain abandoned its allies, left Portugal still at war. Although subjected to pressure from the French Directory and from the Spanish minister, Manuel de Godoy, Portugal remained unmolested until 1801, when Godoy sent an ultimatum and invaded Alentejo. By the Peace of Badajoz (June 1801) Portugal lost the town of Olivenza and paid an indemnity.

From the Peace of Amiens (1802) until 1807 Portugal was once more immune from attack, though subjected to continuous pressure to break off the English connection. By the Berlin decree of Nov. 21, 1806, Napoleon sought to close all continental ports to British ships. Portugal endeavoured to maintain neutrality, but the secret Franco-Spanish Treaty of Fontainebleau (October 1807) provided for its eventual dismemberment by Napoleon I and Godoy. Already Gen. Andoche Junot was hastening across Spain with a French army, and on Nov. 27 the prince regent and the royal family and court embarked on a fleet lying in the Tagus River and were escorted by British vessels under the command of Sir Sydney Smith to Brazil. Junot declared the Braganzas deposed, but his occupation of Portugal was challenged in August 1808 by the arrival of Sir Arthur Wellesley (later duke of Wellington) and 13,500 British troops in Mondego Bay. Winning the victories of Roliça (Aug. 17) and Vimeiro (Aug. 21), Wellesley enabled his superiors to negotiate the Convention of Sintra (Aug. 31) by which Junot was allowed to evacuate Portugal with his army. A second French invasion (1808–09) led to Sir John Moore's death at Corunna (January 1809) and the reembarkation of the British forces. In February William Carr (later Viscount) Beresford was placed in command of the Portuguese Army, and in March Marshal N. J. de Dieu Soult advanced from Galicia and occupied Oporto. Wellesley returned to Portugal in April, drove Soult from the north and after his victory of Talavera de la Reina in Spain (July) withdrew to Portugal. The third French invasion followed in August 1810 when Marshal André Masséna with Marshal Michel Ney and Junot entered Beira province. Defeated by Wellington in October at Bussaco near Coimbra, the French found themselves facing the prepared lines of Torres Vedras, north of Lisbon, where they wintered amid great privations. By the spring of 1811 they could only retreat and, on March 5, began the evacuation of Portugal, harassed all the way by English and Portuguese attacks and crossing the frontier after a defeat at Sabugal (April 3).

Portugal made peace with France on May 30, 1814. It was represented at the Congress of Vienna but played little part in the settlement. However, the series of Anglo-Portuguese treaties concluded between the years 1809 and 1817 was important insofar as it extended many of the conditions of the Anglo-Portuguese alliance to Brazil and had an influence on the future of Africa. England's efforts to get Portuguese collaboration in suppressing the slave trade resulted in the treaty of Jan. 22, 1815, and in the additional convention of 1817, by reason of which Portugal's claims to a considerable part of Africa were admitted.

2. Constitutionalism.—The Napoleonic Campaigns had caused great devastation in Portugal, and the absence of the royal family and the presence of a foreign commander (Beresford) combined with revolutionary agitation and the influence of Spanish liberalism to produce an atmosphere of discontent and restlessness. On Dec. 16, 1815, Brazil was raised to the rank of a kingdom united with Portugal, and John VI, who succeeded in March 1816, showed no desire to return to Portugal. In 1817 Beresford suppressed a conspiracy in Lisbon, and the Masonic leader Gen. Gomes Freire de Andrade was executed. Unrest increased, and when Beresford himself went to Brazil (March 1820) to press John to return, a constitutionalist revolution began in Oporto (Aug. 24, 1820),

spread over the country and led to the formation of a junta in Lisbon (Oct. 4). On Beresford's return (Oct. 10) he was not allowed to land, and British officers were expelled from the army. A constituent assembly was summoned which drew up a very "democratic" constitution, thus confronting John VI with an accomplished fact.

John's reluctance to return was at last overcome and he left his elder son Pedro to govern Brazil, landing at Lisbon on July 4, 1821. He swore to uphold the constitution, but his wife, Carlota Joaquina, and their second son, Dom Miguel, refused to take the oath and were sentenced to banishment, though this was not carried out. The Portuguese constitutionalists, not appreciating the determination of Brazil not to yield up its status as a kingdom, sought to compel Pedro to return; but he, rather than sacrifice the rule of the Braganças in Brazil, declared for Brazilian independence (Sept. 7, 1822) and became emperor of Brazil as Pedro I. This enabled his brother Miguel to appeal to absolutist forces in Portugal to overthrow the constitutionalists, and an insurrection led by Miguel almost succeeded (April 30, 1824); but through the action of the foreign ministers John VI was restored and Miguel went into exile in Vienna (June 1824).

John VI acknowledged the independence of Brazil in 1825, assuming *pro forma* the imperial title and then yielding it to Pedro, but when John died (March 10, 1826) no provision had been made for the succession except that his daughter Maria Isabel was now named regent. Pedro, as Pedro IV of Portugal, issued from Brazil a charter providing for a parliamentary regime by the authorization of the monarchy and not based on the sovereignty of the people. He then made a conditional abdication (May 1826) of the Portuguese throne in favour of his daughter Maria da Glória, aged seven, provided that she should marry her uncle Miguel and that he should swear to accept the charter. This compromise could not be effective. The absolutists had hoped that Pedro would resign all rights to the Portuguese crown, and the council of regency hesitated to publish the charter until Gen. João Carlos de Saldanha (later duque de Saldanha) forced their hand. In October 1827 Miguel took the oath and was appointed regent, landing in Lisbon in February 1828. His supporters at once began to persecute the liberals. A form of *Cortes* met in Lisbon, and in July 1828 repudiated Pedro's claims and declared Miguel rightful king.

Only the island of Terceira in the Azores sustained the liberal cause. In June 1829, however, a regency on behalf of Maria da Glória was set up in Terceira, and in 1831 Pedro, having abdicated the Brazilian throne, went to Europe and began to raise money and men for the conquest of Portugal. In February 1832 the expedition sailed to Terceira and in July the liberals, led by Pedro, disembarked at Mindelo near Oporto, which city they soon occupied. However, the rest of the country stood by Miguel, who besieged the liberals in Oporto for a year (July 1832–July 1833). By now Miguelite enthusiasm had waned, and António José de Sousa Manuel, duque de Terceira, and Capt. (later Sir) Charles Napier, who had taken command of the liberal navy, made a successful landing in Algarve (June 1833). Terceira advanced on Lisbon, which fell in July 1833, and Miguel capitulated at Évora-Monte in May 1834.

The War of the Two Brothers ended with the exile of Miguel (June) and the death of Pedro (Sept. 24, 1834). Maria da Glória became queen as Maria II (1834–53) at the age of 15. While Maria necessarily came under the influence of the successful generals of the civil war, her chief aim was to defend her father's charter (which had been *octroyée*, i.e., granted by the king) from those who demanded a "democratic" constitution like that of 1822, asserting the sovereignty of the people. In September 1836 the latter, thenceforth called Septembrists, seized power. The chartist leaders rebelled and were exiled, but by 1842 the Septembrist front was no longer united and António Bernardo da Costa Cabral restored the charter. In May 1846 the movement of Maria da Fonte, a popular rising against certain improvements in industry and reforms in public health in which almost all parties joined, put an end to Costa Cabral's government but left Portugal divided between the Septembrists, who held Oporto, and Saldanha, now in Queen Maria's confidence, in Lisbon. Saldanha negotiated for the

intervention of other members of the Quadruple Alliance (formed in April 1834 by England, France, Spain, and Portugal), and a combined British and Spanish force received the surrender of the Oporto junta in June 1847 and ended the war with the Convention of Gramido (June 29, 1847). Saldanha governed until 1849, when Costa Cabral resumed office only to be overthrown in April 1851. Saldanha then held office for five years (1851–56), and the period of peace at length permitted the country to settle down.

Maria II was succeeded by her eldest son by her second husband, Ferdinand of Saxe-Coburg, Pedro V (1853–61), who married Stephanie of Hohenzollern-Sigmaringen in 1853. He gave promise of being a capable and conscientious monarch, but died of typhoid fever on Nov. 11, 1861. His brother Luís I (1861–89) seemed to have inherited a country that had recovered from the Napoleonic invasions and from civil wars, political strife, and *pronúciamentos*. But although the main parties were not defined as Historicals (i.e., radicals) and Regenerators (or moderates), the alternation of governments gradually ceased to reflect popular feeling, and in the last years of Luís' reign republicanism was already gaining ground.

With the accession of Carlos I (1889–1908), a serious dispute with Great Britain occurred. Portugal's possessions in Africa had been recognized by Great Britain in the treaty of 1815; but more recently Germany and Belgium had entered the colonial field and at the Conference of Berlin (1885) the definition of "effective occupation" was adopted as the basis for possession of colonial territories. A colonial movement had gained momentum in Lisbon, and a Portuguese scheme, known as the "Rose-Coloured Map," which laid claim to a colony stretching across Africa from Angola to Mozambique, was recognized by France and Germany (1886). Although the marquess of Salisbury registered a protest (1888),

the Portuguese foreign minister Henrique de Barros Gomes sent Maj. Alexandre de Serpa Pinto to the Shiré Highlands in Nyasaland, with a view to their annexation. He became involved in a fight with the Makololos, who were under British protection, and a series of communications between London and Lisbon ended in the dispatch of the British ultimatum of Jan. 11, 1890, demanding the withdrawal of all Portuguese from the Shiré. Amid great popular excitement Barros Gomes had no alternative but to comply, and the government resigned. The incident caused the deepest resentment in Portugal, not only against the ancient ally but also against the monarchy, which was menaced by a republican revolution in Oporto (Jan. 31, 1891).

During the following years, the Portuguese African colonies were defined as a result of the Anglo-Portuguese treaty of July 1891, but the financial position of the country was so bad that it seemed unlikely that the efforts to consolidate the African colonies would succeed. In 1897 it became clear that Portugal would require a considerable loan, and Germany demanded to partake in any assistance that was offered. On Aug. 30, 1898, A. J. (later the earl of) Balfour, temporarily in charge of the British Foreign Office, concluded a secret Anglo-German convention assigning spheres of influence in the Portuguese colonies to Great Britain and Germany in the event of such a loan. This was, however, denounced by the prime minister, Lord Salisbury, and in 1899 when the Germans endeavoured to persuade the Portuguese to accept a loan, Salisbury's action and the imminent danger of a conflict in the Transvaal caused an Anglo-Portuguese approximation. On Oct. 14, 1899, the ancient treaties of alliance were reaffirmed in a secret declaration, later made public (the so-called Windsor Treaty).

Meanwhile, the financial situation showed little improvement, and the republicans continued to progress. In 1906 João Franco, formerly a Regenerator, came to power as champion of the failing monarchist cause. Unable to obtain the support of the other monarchists, he began to govern by decree. Although Franco bravely undertook to reform the finances and administration, he was accused of illegally advancing money to the king. These scandals were followed by rumours of plots, and on Feb. 1, 1908, Carlos and his heir, Luís Filipe, were assassinated as they rode in an open carriage in Lisbon. Whether or not the regicides were isolated fanatics or agents of a wide organization such as the *Carbonarios*, a republican secret society, the deed was applauded by the republicans, who now prepared for a final attack on the monarchy.

King Manuel II (1908-10) found no unity among the monarchist politicians. The general election of August 1910 showed republican majorities in Lisbon and Oporto, and on Oct. 3 the murder by a madman of one of the republican leaders, the distinguished physician Miguel Bombarda, offered the pretext for a rising that was already organized. Armed civilians, soldiers, and the men aboard some ships in the Tagus began the republican revolution on Oct. 4 and, after faltering, their movement, in which António Machado dos Santos played the predominant part, succeeded on Oct. 5. Manuel escaped to Ericeira and thence by sea to Gibraltar and to England. On his death in 1932 his body was returned to Portugal. (H. V. L.; X.)

3. Social and Economic Conditions.—From the time of the Portuguese overseas conquests the flow of wealth from the new territories and trading posts, although never sustained, was yet sufficient to discourage the building of a sound home economy. The favourable financial position of the late 15th century, derived from trade in slaves, gold, and spices, did not long survive into the 16th century, when the expenses of maintaining some far-flung and unproductive foreign stations and the depredations of pirates quickly absorbed any surpluses. There were few native industries. Not only were manufactured goods such as cloth, tapestry, and metalware imported, but also basic foodstuffs, salt meat, cured fish, poultry, and dairy produce. Agriculture was little regarded and insufficient land was available for small holdings. During the years of Spanish domination the ports were closed to English merchants and by the time they were reopened after 1640 the flow of trade had found new channels and the Dutch and English had outstripped Portugal as colonial powers. The discovery of gold in Brazil at the end of the 17th century brought a brief revival, but lack of

planning and of precautions against fraud and contraband soon lost much of the profit to the Portuguese crown. The 18th century saw a series of protectionist measures, many introduced by Pombal. The Methuen Treaty with England (1703) had strengthened the port wine trade at the expense of Portuguese cloth; later further attempts were made to improve the export value of port wine. Support was also given for the production of woolen goods, linen, paper, porcelain, and cutlery, and to the tunny and sardine fisheries. But the absence of an educated *bourgeoisie* made real development in industry and commerce very difficult and Portugal had to wait until the 20th century for any sustained attack upon its economic difficulties. (X.)

H. THE REPUBLIC, FROM 1910

The new regime formed a provisional government under the presidency of Teófilo Braga, a well-known writer. This in turn issued a new electoral law giving the vote to all adult Portuguese and presided over the election of a constituent assembly which opened on June 19, 1911. The constitution was passed on Aug. 20, and the provisional government surrendered its authority on Aug. 24 to the new president, Manuel José de Arriaga.

1. Evolutionists, Unionists, and Democrats.—Although a monarchist invasion was unsuccessfully attempted by Henrique de Paiva Couceiro in October 1911, the main danger to the new regime came from its internal divisions. For the moment, it was fairly united in denouncing monarchism and persecuting the church. The religious orders were expelled (Oct. 8, 1910) and their property confiscated. The teaching of religion in primary schools was abolished and the Roman Catholic Church disestablished. The conditions under which Catholics and monarchists were imprisoned attracted attention abroad, and it was only gradually that this legislation was modified. New universities were founded at Lisbon and Oporto, but the task of destruction proved easier than that of construction, and before long the republicans were divided into Evolutionists (moderates), led by António José de Almeida; Unionists (centre party), led by Manuel Brito Camacho; and Democrats (the left wing), led by Afonso Augusto da Costa. A number of prominent republicans had no specific party. The whirligig of republican political life offered little improvement on the monarchist regime, and in 1915 the army showed signs of restlessness. Gen. Pimenta de Castro formed a military government and permitted the monarchists to reorganize, but a Democratic revolution (May 14) led to his arrest and consignment to the Azores. President Arriaga resigned and was succeeded by Braga and then by Bernardino Machado (Oct. 5, 1915-Dec. 8, 1917). The Democratic regime, in which Costa was paramount, was ended by the revolution (December 1917) of Maj. Sidónio Pais, who established a "New Republic" of a right-wing tendency, supported at first by the Unionists. On their withdrawal (March 1918) a new National Republican Party gained control. Sidónio Pais' "presidentialist" regime was abruptly ended with his assassination on Dec. 14, 1918, when, after the provisional presidency of Adm. João de Canto e Castro, power passed gradually back to the Democrats.

Meanwhile, on the outbreak of World War I, Portugal had proclaimed its adhesion to the English alliance (Aug. 7, 1914), and on Nov. 23 committed itself to military operations against Germany. On Sept. 11 a first expedition left to reinforce the African colonies, and there was fighting in northern Mozambique, on the Tanganyika frontier, and in southern Angola, on the frontier of German South West Africa. In February 1916 Portugal seized German ships lying in Portuguese ports and Germany declared war (March 9). A Portuguese expeditionary force went to the western front in 1917, under Gen. Fernão Tamagnini de Abreu e Silva; on April 9, 1918, they were under heavy German attack in the Battle of Lys. By the Treaty of Versailles (1919) Portugal received 0.75% of the indemnity payable by Germany and the Kionga (Quionga) area captured by Portuguese forces in East Africa.

Almeida completed his term of office as president (Oct. 5, 1919-Oct. 5, 1923); but ministries succeeded one another in rapid succession. In 1921 the founder of the republic, António Machado Santos, was among those murdered by enemies of Sidónio Pais; and

although António Maria da Silva contrived to govern in the Democratic interest for a year and nine months, his fall in November 1923 was followed by a number of short-lived ministries. Revolutionary movements grew more frequent as the Democratic Party lost its cohesion, and there were signs in the army of impatience with the political turmoil. Although the Democrats obtained a clear majority in 1925 and Manuel Teixeira Gomes (1923-25) yielded the presidency to Bernardino Machado without incident, a military revolt occurred in Lisbon on Feb. 2, 1926. It was quelled, but on May 28 Commander José Mendes Cabeçadas and Gen. Manuel de Oliveira Gomes da Costa rebelled at Braga. Machado was deposed, and a provisional government was formed.

2. The "New State."—At first Cabeçadas was head of the provisional government and Gomes da Costa minister of war; but the former was regarded as too close to the politicians, and Gomes da Costa unseated him. Within a few weeks he too was deposed and his place taken by his foreign minister, Gen. António Oscar de Fragoso Carmona (July 9, 1926). Carmona was elected president of the republic in March 1928 and remained in office until his death in April 1951. After an attempt at revolution in February 1927, which resulted in considerable bloodshed, Carmona's government was not seriously interrupted. The program of the military regime was merely to restore order. To remedy the financial plight of the country, it had been proposed to borrow money from the League of Nations, but the conditions offered included supervision of the finances, which was regarded as offensive to national sovereignty. The loan was, therefore, rejected, and Carmona in 1928 called on António de Oliveira Salazar to take the Ministry of Finance.

Salazar, professor of economics at Coimbra University, fully controlled all expenditure and revenue and embarked on a complete overhaul of the administration. As minister of finance from 1928 to 1940 he produced an unbroken series of budgetary surpluses, which restored Portugal's financial credit. As prime minister from 1932 he ushered in the new Constitution of 1933 (see below); as minister of colonies in 1930, he prepared the Colonial Act governing the administration of Portugal's colonial empire; and as minister for foreign affairs (1936-47) he guided Portugal through the difficulties caused by the Spanish Civil War, and during World War II practised a form of neutrality compatible with the Anglo-Portuguese Alliance. In May 1940 a concordat was signed with the Vatican, which clarified the position of the Catholic Church in Portugal. The Church was reconfirmed in its possession of most of the property it had held before 1910, religious instruction was restored in state schools, private church schools were allowed, and Church marriages were to be recognized. On the death of Carmona in 1951, Salazar assumed under the constitution the attributes of the presidency, until Gen. Francisco Craveiro Lopes was sworn in as president in August 1951.

By 1953 Salazar had been a member of the government for 25 years. His "New State," as defined by the Constitution of 1933, provided for a president, elected for a period of seven years, who appointed a prime minister and a variable number of ministers; a national assembly of deputies elected quadrennially as a block, meeting for at least three months annually; and a corporative chamber consisting of representatives of trades and professions and acting as a consultative assembly. At general elections from 1934 onward all seats in the National Assembly went to government (National Union Party) supporters, although in 1949, 1953, and 1957 there were a few opposition candidates. In January 1961 a group of anti-Salazar insurgents, led by Henrique M. Galvão, seized the Portuguese cruise ship "Santa Maria" in the Caribbean Sea. The seizure was said to have been planned to coincide with uprisings in Angola and other Portuguese colonies, but no rebellions occurred and the insurgents were granted political asylum in Brazil. A minor military revolt, the first against Salazar, in January 1962, was crushed at Beja. Rear Adm. Américo Deus Rodriguez Tomás succeeded Lopes as president in 1958.

Throughout 1954 India's attempts to absorb Goa were rebuffed and in July 1955 the Indian government severed diplomatic relations with Portugal. This was followed in August by mass invasions of the Portuguese colonies in India by "passive resisters." These were repelled, with some losses. In December 1955 Portugal

became a member of the United Nations and in February 1956 referred the question of free access through Indian territory to the enclaves of Dadrá and Nagar Havili (Aveli) to the International Court of Justice which, in April 1960, recognized Portugal's right to the enclaves and also recognized India's right to control access to them through Indian territory. Finally, on Dec. 18, 1961, India sent troops into Goa, Diu, and Damão, and the next day the Portuguese surrendered. Portugal's control over its remaining overseas territories was further threatened by the rebellion in Angola, which broke out in February 1961. By 1963 about 50,000 Portuguese troops were committed to the territory. (H. V. L.; X.)

V. POPULATION

The population of continental Portugal with the Azores and Madeira was 8,851,289 in 1960. The overseas provinces, with an area of 805,325 sq.mi. (2,085,794 sq.km.), had a population of about 12,900,000 in 1960. A decrease in the rate of emigration in the early years of World War II was reflected in a rather steep increase of population, and the urban population grew more rapidly than the rural because of internal migration. In 1960 the population of the chief towns was: Lisbon 817,326; Oporto 305,445; Coimbra 50,168; and Setúbal 44,177.

The Portuguese population has increased rapidly in relation to the size of the country. The birth rate, at 24.22 per 1,000 in 1960, was one of the highest in Western Europe. The death rate (10.76 per 1,000) was also high. The population is unevenly distributed, all but one-seventh inhabiting the provinces north of the Tagus.

Area and Population of Portuguese Districts
(Metropole only)

District	Area (sq.mi.)	Population (in 000s)		Density (per sq.mi.) 1960
		1950	1960	
Aveiro	1,046	477.2	522.2	499.3
Beja	3,954	286.8	268.9	68.0
Braga	1,054	541.4	593.6	563.2
Bragança	2,527	227.1	230.3	91.1
Castelo Branco	2,588	320.3	310.7	120.1
Coimbra	1,527	432.0	433.6	284.0
Évora	2,855	219.6	215.2	75.4
Faro	1,958	325.9	312.5	159.6
Guarda	2,122	304.4	276.5	130.3
Leiria	1,326	389.2	400.3	301.9
Lisbon	1,066	1,226.8	1,402.6	1,315.7
Oporto	881	1,052.7	1,191.5	1,352.4
Portalegre	2,274	197.0	183.8	80.8
Santarém	2,583	453.2	462.1	178.9
Setúbal	1,989	324.2	376.1	189.1
Viana do Castelo	814	274.5	275.3	338.5
Vila Real	1,637	317.4	322.6	197.1
Viseu	1,938	487.2	477.5	246.4
Total	34,139	7,856.9	8,255.4	241.8

The density of population (1960) in continental Portugal reached 1,352.4 per square mile in the district of Oporto but only 68.0 in Beja. The average for the whole country is 250.5 per square mile (96.7 per square kilometer). The island of Madeira is more thickly peopled than the mainland (except for Oporto and Lisbon), with 873.2 per square mile; the Azores have 366.7 per square mile.

Areas such as Minho are seriously overpopulated. The division of land has proceeded so far that it is often uneconomically cultivated. The less-populated areas, on the other hand, will not bear any large increase, since the soil is too poor to carry more inhabitants. Therefore, there has for long been a considerable emigration of Portuguese, principally to Brazil but also to the United States and Canada, other parts of Latin America, and Africa.

VI. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution.—The Portuguese state in the 1960s remained organized according to the Constitution of 1933, approved by plebiscite and modified by subsequent laws. The constitution has 13 articles which fall into two sections: (1) fundamental guarantees; (2) political organization of the state. It is in force throughout the national territory, which comprises the mother country and the overseas provinces. In the Portuguese view there are no colonial territories subject to the metropolitan community; there is a single national community covering a territory which is jurisdictionally one despite geographical separation.

2. Government.—The Portuguese state is a unitary and corporative republic. Sovereignty is vested in the nation and its ex-

ercise is delegated to the head of the state (the president of the republic), the National Assembly, the government, and the courts of justice. The president of the republic is elected for seven years by the nation, through an electoral college consisting of members of the National Assembly and the Corporative Chamber, and representatives of the municipalities and of the legislative or governing councils of the overseas provinces. He chooses the head of the government and appoints ministers whom the latter proposes. He has the power to convene and dissolve the assembly.

The president is assisted by the Council of State (with merely consultative powers but with important functions of verification) composed of 15 members, 5 *ex officio* and 10 appointed for life. The government is composed of the chairman of the council of ministers and of the ministers. Ministers are responsible to the chairman of the council. The government can issue decree laws having the force of law and is independent of the vote of parliament. The chairman of the council is the delegate of the head of state and, as such, holds the power of government.

The National Assembly consists of one chamber composed of 130 members elected by universal and direct suffrage for four years. Members have the right to remuneration. Ministers who are members of the assembly may not take part in its proceedings (except for committees), but the government selects a member to represent its point of view in debates. The parliamentary session is normally for three months annually, beginning on Nov. 25. Both the government and members of the assembly have the right to initiate legislation, but members may not introduce bills which would involve increases in state expenditure or decreases in state revenue. Besides the discussion of political and administrative measures and the voting of bills after consulting the Corporative Chamber, the assembly has certain specific functions such as the approval of the general principles of the organization of national defense and of the law courts, and the creation of banks.

The Corporative Chamber represents interests of an administrative, economic, spiritual, and moral character. Its functions are consultative and advisory and its duties include reporting on draft bills and proposals before their discussion by the National Assembly. The chamber normally functions through sessions of one or more of its 12 sections (each of which represents a separate interest), but exceptionally it may meet in plenary session.

3. Local Administration.—The basic unit of the Portuguese local administrative structure is the *concelho*, or municipality, the lineal descendant of the medieval councils. The *concelho* is composed of parishes (*freguesias*), each with its administrative board, and *concelhos* are grouped into districts (18 in all), each with a board. Since 1959 the province has not been an administrative unit, though the provincial names are retained for regional designation. The municipal council comprises representatives of its parishes, of the guilds and syndicates (wage earners, salaried employees, and members of the liberal professions), of the agricultural corporative bodies, and of welfare institutions, etc. Its executive body is the *Câmara Municipal*, whose president is also the representative of the government. The district board is headed by a civil governor, who represents governmental influence in local administration. Each overseas province has a governor, assisted by governmental and legislative councils, who is subject to the Overseas Ministry of the Portuguese government.

4. Taxation.—Various taxes are levied on different forms of income brought in by property, trade and industry, capital gains, etc., and employed persons are taxed not on their actual income but on an assumed average income. There is also a supplementary personal tax, which is progressive and designed to correct anomalies in normal taxation.

5. Living Conditions.—More than 40% of the working population is employed in agriculture, though the development plan for 1959-64 foresaw a displacement of many farm workers. Few skilled workers are unemployed, but an incidence of unemployed unskilled, seasonal workers is sometimes recorded, causing authorities to create employment through public works projects. The country's excess of unskilled labour and lack of skilled technical and scientific workers is being remedied by extending and improving training facilities.

J. ALLAN CASH

MODERN APARTMENT BUILDING IN LISBON

Wages.—Wage levels are settled by agreements in individual spheres of industry. In the early 1960s increases in wages were in general greater than in the past. The increase in the average value of the wage index in 1962 was about 7%. In agriculture, men's wages increased by about 4% in 1961 and official estimates were that the upward trend was continuing.

Housing.—The problem of housing has been much eased by intensive building of modern houses and blocks of apartments, with special attention to housing for the lower income groups in co-operation with the corporative organizations and social welfare bodies. New residential areas have been opened up with houses at low rentals which can become the property of the tenants. Loans are provided to workers for building their own homes.

6. Welfare Services.—The Constitution of 1933 laid down the general principle that the state should promote and encourage provident institutions, and the National Labour Statute of 1933 furthered this aim. The first practical measures were taken from 1935 onward. From the early 1960s four classes of social insurance institutions were recognized: (1) institutions covering the compulsory insurance of employed persons, including the Social Providence Organization for employees (and their dependents) in industry and commerce; People's Centres (*Casas do Povo*) which catered for the rural population, providing benefits and social centres; Fishermen's Centres, providing education and training as well as other benefits; (2) pension and provident schemes for the various professions; (3) provident institutions for state and local government servants (civil and military); (4) voluntary mutual aid (or friendly) societies, which inherit an older tradition; they are private but subject to government inspection. Benefits in the above institutions vary but those included are for sickness, disablement, maternity, and special risks, and also family allowances and old age and widows' pensions. Each industry, trade, and profession (and many individual enterprises) has its own corporative organization which provides social benefits and arbitrates for it in labour tribunals. Both employers and employed are equally

represented in the corporative organizations, which are also linked with public life through the Corporative Chamber on which they are represented.

Health.—Portugal is divided into three hospital zones based on Lisbon, Oporto, and Coimbra. These are subdivided into regions and subregions, providing a network of general and specialized hospitals, sanatoriums, and clinics. In the 1960s about 80% of patients in central hospitals received free treatment, and the state covered about 80% of the expenses of central hospitals. The main hospitals (general and special), medical institutions, and sanatoriums were at Lisbon, Oporto, and Coimbra and numbered about 30.

7. Justice.—Judges are independent of the legislature and government; they are appointed for life, after examination by a board of legal experts, by the Higher Council of the Judicature which is composed of the president of the Supreme Court of Justice and the presidents of the appeal courts. There is a distinction between the courts of justice, which deal with civil, criminal, and commercial cases, and the administrative tribunals which deal with the legality of administrative authorities' decisions. There are separate civil, criminal, commercial, labour, and juvenile courts. Military tribunals deal with offenses by members of the armed forces. The courts range from those of first instance, through appeal courts to the Supreme Court of Justice. The attorney general is represented in all courts and tribunals. The minister of justice is the intermediary between the judicature and the government and coordinates the necessary administrative services (attorney general's department, judicial police, prison services, etc.).

8. Education.—Education is compulsory from the age of seven, and after going through four grades of a primary school, children may attend a secondary technical school, which has five-year commercial and industrial courses, or a secondary high school (*liceu*), which has a seven-year course directed toward university entrance examinations. The state has created the Portuguese Youth Organization, which through extrascholastic activities is concerned with the moral and political training of all primary and secondary school pupils. At these levels both private and state schools are found. Higher education is provided by the three universities of Lisbon (founded 1290; reestablished at Lisbon 1911), Oporto (1911), and Coimbra (1290); in the technical universities of Lisbon and Oporto; and in various technical institutes. The Lisbon Academy of Sciences is the principal learned society and there are numerous other societies and institutes of learning, art, and science, and libraries and museums.

9. Defense.—In peacetime the Ministry of Defense coordinates the activities of the Ministries for the Army and the Navy through a general secretariat for national defense under the direction of the Chief of the General Staff of the Armed Forces.

Besides the Portuguese Army, Navy, and Air Force, there is the National Republican Guard, the Fiscal Customs Guard, and the Portuguese Legion (voluntary patriotic organization). Military service is compulsory and involves 18 months' preliminary training, a period of 8 years on the active strength and a period of 12 years in the reserve, followed by 5 years in the territorial army. Service normally ends at the age of 45. The Portuguese Youth Movement, the Military School, and the Army Pupils Organization provide some paramilitary training.

Continental Portugal in the 1960s was divided into five military regions: Oporto, Coimbra, Tomar, Évora, and Lisbon; and there were separate commands in Madeira and the Azores. There were commands also in each of the overseas provinces. The Navy comprised destroyers, frigates, submarines, and light vessels. Portugal had three air regions: Lisbon, Luanda, and Lourenço Marques. The Air Force was equipped with various types of U.S. aircraft and contributed to the NATO Air Forces.

10. Overseas Provinces.—Portugal has five separate provinces in Africa, one in Asia (Macao or Macau), and one in Oceania (Portuguese Timor). The Portuguese State of India (Goa, Damão, and Diu) is still regarded by the Portuguese as belonging to Portugal (see *PORTUGUESE INDIA*). Angola (Portuguese West Africa) and Moçambique or Mozambique (Portuguese East Africa) on the

African mainland comprise more than 90% of the total area of the overseas provinces. Portuguese Guinea, the Cape Verde Islands, and São Tomé (St. Thomas Island), and Príncipe (Prince's Island) are the remaining African provinces. In China the promontory of Macao on the Canton (Pearl) River lies near Canton and Hong Kong. Timor, the largest of the Lesser Sunda Islands, is divided between Portugal and Indonesia. All these are described in separate articles.

(X.)

VII. THE ECONOMY

Portugal is largely an agricultural country, about half the population deriving its living from farming. Primary products account for four-fifths of the gross national product. Since the revolution of 1926 Portugal has emerged from the state of financial anarchy which had lasted for more than a century, and since 1933, under an economist dictator, has benefited from a balanced budget and steady if unspectacular economic progress. The standard of living is still low, but the government has not neglected economic development and there is a growing middle class. From 1953 two six-year plans were undertaken, the first emphasizing the development of hydroelectric power and the reequipping of the shipbuilding industry, and the second (1959-64) the modernization of the fishing industry, the installation of industrial plants, and assistance to agriculture, especially by means of irrigation in Alentejo. The first plan chiefly involved investments by the public sector; the second showed clear progress with more prominence given to agriculture and manufacturing industries. The long-term stagnation of Portugal's agricultural output and productivity has been a major drag on the economy, which only land reform can effectively alter.

A. PRODUCTION

1. Agriculture.—*Crops.*—Over one-third of metropolitan Portugal is arable land and a great part of this is devoted to cereals. Alentejo and Estremadura produce more than four-fifths of the wheat crop, Minho, Beira Alta, and Beira Litoral two-thirds of the maize (corn), and Trás-os-Montes and Beira Baixa half the rye. An energetic wheat campaign from 1928 lessened the traditional need of cereal imports, but climatic disasters sometimes necessitate supplementary food imports. One-tenth of the productive area is under tree crops, chiefly olives and vines. Two-fifths of the vines are grown on the warm soils derived from limestone of Estrema-

YAN-RAPHO

LOADING CORK ONTO CARTS OUTSIDE SETÚBAL IN THE ESTREMADURA REGION

dura, a province noted for its table wines, though the port wine district of the Douro Valley and the vineyards of *vinho verde* in the northwest are also famous. Olive oil is the country's second most valuable crop and Portugal is the world's third largest producer. Estremadura, Ribatejo, and Alentejo produce between them three-fifths of the total, though olive groves are scattered widely. Rice cultivation, which first developed in the lower valleys of the Vouga and notably the Mondego, had by the mid-1960s 46% of the total rice fields in the newly developed lands of the Serralta-Sado Basin. Dried fruits are important in Algarve, notably carobs, figs, and almonds. The 1962-71 plan aimed to triple the national production of prunes, apples, and citrus fruits. Only 9.5% of the total area is waste or built over, and the remaining uncultivated land is largely under forest or pasture.

Livestock.—North of the Tagus oxen are the chief work animals. Cows are also important, especially in the valleys of the northwest, and horses are reared in Ribatejo in large numbers. Mules are the draft animals of the south where pastures are poor. Alentejo has one-third of all the sheep and goats of the country. The Serra da Estrêla still has considerable importance for the summer transhumance of these animals. The second plan has attempted to expand the livestock industry.

2. Forestry.—Portugal leads the world in the production of cork, which accounts for about one-third of the value of forest products. The cork estates (*montados*) are located chiefly in western Alentejo. Pine woods provide half the income from forest products. Notable are the forests of Leiria and the northwest.

3. Fisheries.—Fishing supports less than one-tenth of the population, although there are numerous small villages whose inhabitants are engaged in this occupation part time. The main fishing ports are Lisbon, Setúbal, Leixões, Figueira da Foz, and Viana do Castelo. Sardines are the chief catch, and there are more than 200 canneries, most of them situated at Setúbal and Matosinhos (near Oporto). Cod is the next important catch by value, and a fleet sails annually to the Newfoundland Banks. The tunny canneries at Olhão and Faro in Algarve and the oyster beds of the Sado and Mondego estuaries are other notable sources of income.

4. Mining.—Portugal has a great variety of minerals, but geological conditions are not suitable for vigorous exploitation. During World War II wolfram was Portugal's "white gold," in one year accounting for half the total foreign earnings. Of more lasting importance is the initial development of steel and tinplate industries, use being made of the two anthracite mines of Pejão and Este near Oporto, and the iron and tin deposits of Torre de Moncorvo (Braganza). However, about three-quarters of the coal required by Portugal must be imported. Since 1938 crude petroleum has been refined near Lisbon.

5. Power.—Until 1945 barely one-third of Portugal's electricity supplies came from hydroelectric power stations, and about four-fifths of the thermal power was dependent on imported coal and oil. However, an ambitious program of building new dams on the Douro, Cávado, Zézere, Ponsul, and Sado rivers has radically altered the situation, the bulk of electricity supplies now coming from hydroelectric stations. The increase in per capita electricity consumption from 60 kw-hr. in the 1930s to 400 kw-hr. in the early 1960s provides a measure of the rate of industrialization. The only gas works in Portugal are in Lisbon.

6. Industries.—Manufacturing provides work for about one-quarter of the working population, but of these employees one-fifth are in textiles and two-fifths in food, shoe, furniture, and civil construction industries. Thus manufacturing activity is still largely directed toward meeting the needs of domestic consumers. Small workshops and domestic crafts prevail, with a marked regional concentration in Lisbon and Oporto and at smaller specialized centres. Eighteen of the 21 towns which have more than 10,000 inhabitants lie north of the Tagus, many of them noted for traditional manufactures. The overwhelming importance of Lisbon and its central position in the country lessen the risk of an underdevelopment problem arising in the south. Developments of the mid-1960s were increases in shipbuilding (notably fishing vessels) and in the production of petrochemicals, cellulose, and chemical fertilizers.

B. TRADE AND FINANCE

1. Foreign Trade.—Portugal's export trade is based on its natural products of cork, wines, mineral ores, timber, resin, and fish. The principal imports are those needed to aid industrialization—machinery, coal, petroleum, iron, steel, and raw cotton—but foodstuffs have also to be imported. Apart from the Overseas Provinces (exempt from customs since January 1964), Portugal's main trading partners are the countries of the European Economic Community, the U.K., and the U.S.; it belongs to the European Free Trade Association (EFTA). Portugal has normally a trading deficit but this is usually offset by invisible earnings (chiefly emigrants' remittances), and trade surplus from overseas territories.

2. Banking and Currency.—The sole bank of issue is the Bank of Portugal, founded in 1846; its statutes were revised in 1931. The National Development Bank began operations in 1960; most of its capital has been subscribed by the government.

The Portuguese monetary unit is the escudo, subdivided into 100 centavos. In the early years of the republic Portuguese finances were chaotic and the escudo was successively devalued from 3s.6d. (U.S. \$0.85) to little more than 2d. (\$0.04). In 1949 it was stabilized at 80.5 escudos to £1 sterling (28.75 to \$1). Portugal is a member of the International Monetary Fund, the International Bank for Reconstruction and Development, and the Organization for European Co-operation and Development.

3. National Finance.—Improved methods of collecting taxes have contributed to the increase in the national revenue. About nine-tenths of current receipts are accounted for by direct and indirect taxation, compared with only seven-tenths in the 1930s.

C. TRANSPORT AND COMMUNICATIONS

As only about 5% of Portugal's trade passes overland to Spain, communications have been oriented seaward. Coastal shipping carries about one-third of all domestic traffic by weight. About nine-tenths of all shipping is handled by the ports of Lisbon, Oporto, and Setúbal. These form the main axis of communication by road and rail. The system of partially electrified, broad-gauge railways is partly state owned. In 1956 a 15-year plan for highway improvement was initiated, including a motorway between Lisbon and Oporto and a bridge over the Tagus south of Lisbon. Road

PAUL ALMAY

BARRELS OF PORT WINE FOR EXPORT ON THE DOCKS OF OPORTO. THE WINE IS PRODUCED IN THE DOURO VALLEY

transport, however, is still of relatively small importance.

Since 1937, when British and U.S. airlines were granted landing rights, air transport has developed rapidly, aided by the construction of airfields at Portela (near Lisbon), on Santa Maria Island (Azores), on Sal Island (Cape Verde Islands), and on Porto Santo Island (Madeira). Transportes Aereos Portugueses, formerly publicly but now privately owned, provides services to the Overseas Provinces. Despite the decrease in aircraft landings, passengers, and notably cargo, have shown a significant increase.

Radio broadcasting is mainly under the control of the national corporation Emissora Nacional de Rádiodifusão. This also provides broadcasts in English, French, and Spanish under the general name of Voice of the West. There are also some small private stations including Rádio Renascença, a Roman Catholic station. Television is controlled by a private limited-liability company, Rádiatelevisão Portuguesa. There are worldwide radio-telegraph and telephone connections and telex facilities.

Gibbons (1939); Luis Teixeira, *Perfil de Salazar, su vida y su tiempo* (s.d.); also Salazar's own *Discursos* (1928-50) and *Doctrine and Action: Internal and Foreign Policy of the New Portugal, 1928-1939*, Eng. trans. by R. E. Broughton (1939). Michael Derrick, *The Portugal of Salazar* (1938) is a general account. Current history and statistics are summarized annually in *Britannica Book of the Year*.

PORTUGUESA, a state of Venezuela, occupies the northeast section of the western llanos (q.v.). The state takes its name from the Portuguesa River, which is a part of the Orinoco River drainage system. Portuguesa has an area of 5,869 sq.mi. (15,200 sq.km.). With an increase in population from 34,000 in 1941 to 203,707 in 1961, it is one of the most rapidly growing states of Venezuela. The capital, Guanare, founded in 1591, had a population of 18,476 in 1961. Acarigua is the principal commercial centre of the state. Livestock raising dominates the economy and rice, coffee, cotton, tobacco, cocoa, and corn (maize) are grown. At Turén, in the district of the same name, the national government sponsored a planned agricultural community which was expected to establish the best means of bringing the vast llanos under cultivation. The Virgin of Coromoto, patron of Venezuela, is associated with the parish church in Guanare, and thousands annually visit the city to pay homage to the venerated image. (J. J.)

PORTUGUESE EAST AFRICA (MOZAMBIQUE; officially PROVÍNCIA DE MOÇAMBIQUE), an overseas province of Portugal and the most populous and second largest (after Angola) of the five Portuguese African possessions, lies on the east coast of Africa between Tanzania and South Africa. Its area is 297,846 sq.mi. (771,124 sq.km.), about seven times the size of Portugal itself and about the size of Texas. From north to south it is about 1,300 mi. (2,100 km.) long. The frontier is very irregular, and the territory varies in width from 56 mi. (90 km.) in the south to 400 mi. (640 km.). It takes its name from the island and town of Moçambique or Mozambique (q.v.), formerly the capital. The modern capital is Lourenço Marques (q.v.).

PHYSICAL FEATURES

The coastline extends from 10°27' S to 26°52' S and makes a double curve on a northeast-southwest axis. Its length is about 1,736 mi. (2,795 km.). In the extreme south, about 40 mi. (64 km.) N of the South African frontier, is the great basin of Delagoa Bay (q.v.; officially Baía de Lourenço Marques) on which stands

the capital. North of this the coast is low-lying and sandy or swampy as far as the deep indentation of the Zambezi Delta. From the Zambezi northward the coast is studded with small islands, mainly of coral formation, on one of which is the town of Mozambique. North of this are high rocky headlands and rugged cliffs. Porto Amélia stands on the great natural harbour of Pemba Bay. The territory is rich in rivers, about 50 of which flow into the Indian Ocean, including the Zambezi in the centre, the Limpopo in the south, and the Ruvuma in the north.

The Zambezi divides the province in two. To the south the coastal plain is much deeper, and only a small part of the high plateau falls in Portuguese territory. In the centre Mt. Gorongosa reaches 6,112 ft. (1,863 m.), and farther north there are several ranges. Niassa District has more than 20 groups of mountains more than 4,000 ft. (1,200 m.) high, and Namuli Peak reaches 7,936 ft. (2,419 m.). Southeast of Lake Nyasa (part of the eastern shore of which is in Niassa District) is a high range which drops 3,000 ft. (900 m.) in 6 mi. to the level of the lake. The highlands along the Rhodesian border reach about 9,000 ft. (2,700 m.).

Geology.—The central plateau consists of gneisses, granites, and schists which in part or in whole belong to the Archean System. Rocks of the Karroo Period occur in the Zambezi Basin, where at Tete they contain workable seams of coal and have yielded plant remains of Upper Carboniferous age. Sandstones and shales, possibly of Upper Karroo age, form a narrow belt at the foot of the plateau. Upper Cretaceous rocks crop out from beneath the superficial deposits along the coastal belt between Delagoa Bay and Mozambique. The highest Cretaceous strata occur in Conducia, where they contain the huge ammonite *Pachydiscus conduciensis*. The Eocene formation is well represented in Gaza District by the nummulitic limestones which have been found to extend for a considerable distance inland. Basalts occur in the Zambezi Basin.

Climate.—There are two meteorological zones. North of the Zambezi seasons are monsoonal, October–March being hot and wet, April–September cooler and dry. To the south, where an anticyclonic regime prevails, seasons are similar, but less well defined. Lourenço Marques, in the extreme south, has an annual mean temperature of 72° F (22.2° C). Quelimane, in the centre near the coast, has an annual mean of 85° F (29.4° C), while at Tete, in the interior, about 260 mi. (418 km.) up the Zambezi, the annual mean is 78° F (25.6° C). The annual extremes are much greater on the coast than in the interior. The range is similar in the north. On the uplands and plateaus the climate is more temperate.

Average annual rainfall figures (in inches; millimetres in parentheses) are: Lourenço Marques 31 (787); Beira 60 (1,524); Quelimane 56 (1,422); Mozambique 31 (787); Tete 21 (533); and Vila Cabral 44 (1,127).

Vegetation.—The soils of Mozambique are predominantly poor and sandy. Three-quarters of the territory is covered with open woodland mixed with savanna and steppe, which can be subdivided into three types of vegetation: (1) moderately dry with much *Brachystegia* and *Julbernardia*; (2) relatively drier undifferentiated types; and (3) especially dry types, dominated by *Colophospermum mopane*. The first type is general throughout the northern half of the territory.

Six palms are found, including the coconut, which is common in the coastal regions, and the date palm, mostly in marshy ground and near rivers. A kind of cedar is found in the lower forests, and ironwood (suitable for high-class furniture) and ebony are common. A large African mahogany (*Khaya senegalensis*), found in ravines and by riverbanks, affords durable and easily worked timber; other timbers include pod mahogany, used for furniture and vehicles; *m'bila* (*Pterocarpus*) or bloodwood; *ziba* (*Dialium schlechteri*), a valuable hardwood; and *monhe* or *gone* (*Adina*), similar to teak. Several varieties of *Vitex* and of *Ficus*, notably the sycamore fig (*Ficus sycamorus*), bear edible fruit.

Excellent hardwood is obtained from a species of *Grewia*. Other characteristic trees are the mangrove (along the seashore), sandalwood, gum copal, baobab, and bombax, and, in the lower plain, dracaenas (dragon trees), many species of creepers and flowering shrubs, and several prickly shrubs. Acacias are numerous, including the gum-yielding variety, while *Landolphia* rubber vines grow

freely in the forests. The bamboo is common, and spear grass is abundant along the riverbanks and the edges of the marshes.

Animal Life.—Among the commoner mammals are the elephant, black rhinoceros, lion, leopard, spotted hyena, jackal, serval, civet cat, genet, hunting dog, and mongoose. The rivers and marshes are the home of hippopotamuses, though they have deserted the lower Zambezi. The wart hog and the smaller red hog are common in open country. A species of zebra is plentiful, and herds of buffalo are numerous in the plains and in open woods. Many antelopes are found, and the giraffe, though scarce, also occurs. Scaly anteaters are fairly numerous, and rodents are common. There are several kinds of monkeys and lemuroids. Crocodiles, lizards, chameleons, and land and river turtles are all very numerous, as are pythons, cobras, puff adders, and vipers. Centipedes, scorpions, and insects abound. Among insects, mosquitoes, locusts, tsetse and hippo flies, cockroaches, phylloxera, termites, and soldier ants are common plagues.

Flamingoes, cranes, herons, storks, pelicans, and ibises are found, including the beautiful crested crane and the comparatively rare saddle-billed stork. The eagle, vulture, kite, buzzard, and crow are well represented, and guinea fowl, partridge, bustard, quail, teal, widgeon, and mallard are all common. Gregarious small green parrots move through the trees in search of fruit.

Gorongosa National Park (1,150 sq.mi. [2,979 sq.km.]) is one of the finest game parks in southern Africa. There are four other game reserves in the territory: Ruvuma, Gilé, Marroneu, and Maputo. Of these, only Gorongosa is open to tourists, but 16 tourist zones have been set aside for safari hunting.

THE PEOPLE

The 1960 census showed the total population of Mozambique to be 6,578,604, of whom 6,430,530 were African, 97,268 European, 31,465 mixed, 17,243 Indian, and 2,098 others. The number of Europeans had grown from 48,910 in 1950 to 65,598 in 1955 to 97,268 in 1960, primarily as a result of immigration from Portugal.

Intermarriage between Europeans and Africans has not been encouraged, although miscegenation has probably been greater than the census figures indicate. While many mulatto children are accepted as family members by the Portuguese parent and raised without discrimination in Portuguese society, there are limitations to the fulfillment of political and administrative ambitions.

Theoretically, there is no colour bar in Mozambique, the only legal criterion for social acceptability being that the individual is "civilized." For the African this means becoming literate in Portuguese, acquiring a Portuguese education, and being Christian. In 1955 only 4,554 individuals, less than 0.1% of the African population of Mozambique, were so assimilated. The official estimate for 1960 envisaged only 5,020 *assimilados*. The influx of Portuguese settlers that began in the 1950s, together with the further entrenchment of the white populations of southern Africa, is creating a situation in Mozambique where the culture bar is virtually synonymous with the colour bar.

The mean population density (1960 census) is 22.1 persons per square mile, but the distribution is irregular, ranging from 6.0 in Niassa District to 111.6 in Lourenço Marques District. Of the Europeans, 63.8% live in Lourenço Marques and Manica e Sofala districts, where they are concentrated primarily in the cities of Lourenço Marques and Beira. African population density is greatest in the districts of Zambézia and Moçambique. (For district populations and densities, see below, *Administration and Social Conditions*.)

Tribal Distribution.—The main peoples in the north are the Yao, between Lake Nyasa and the Msalu River; the Makonde in the extreme northeast; and the Makua-Lomwe, who dominate the districts of Cabo Delgado, Moçambique, and Zambézia, numbering about 2,500,000. All these people are matrilineal, as are the Malawi groups who live north of the Zambezi in Tete District. South of the Zambezi and north of the Sabi River are the patrilineal Shona groups, including the Manyika and Ndaou. South of the Sabi are the patrilineal Hlengwe, Thonga, Ronga, and the Chopi. The African population of the Zambezi Valley is ethnically mixed, it being a transition zone between the matrilineal people to

the north and the patrilineal people to the south. Swahili live on the coast from Cape Delgado down to António Enes.

Religion.—The Africans mainly practise their traditional religions, but an estimated 800,000 are Muslims. There are nearly the same number of African Roman Catholics and some 200,000 Protestants. The position of the church is defined by the Portuguese-Vatican concordat and missionary agreement of 1940, which created a metropolitan see at Lourenço Marques, to which the four dioceses of Beira, Quelimane, Nampula, and Porto Amélia are suffragan. There is freedom of worship, and Lourenço Marques has, in addition to the modern Roman Catholic cathedral, an Anglican pro-cathedral, a Methodist church, a synagogue, a mosque, and a Chinese temple.

Languages.—Portuguese is the official language, but many European inhabitants also speak English, mainly because the hinterland is surrounded by English-speaking areas. French is widely spoken among the upper levels of Portuguese society. All the Africans are Bantu-speaking. (H. V. L.; A. A. G. P.; E. A. A.)

HISTORY

Early Exploration and Trade.—Between the 11th and the 15th centuries the Mozambique coast as far south as Sofala was linked politically and commercially to the coastal city-states north of Cape Delgado. Arab and Swahili traders penetrated inland from Sofala and up the Zambezi into what later became Manica e Sofala District. This was the situation the Portuguese found when Vasco da Gama put in at Mozambique Island early in March 1498. Just before this he had discovered and landed at what he called the Rio do Cobre (the Inharrime) and the Rio dos Bons Sinais (the Quelimane, the northern outlet of the Zambezi). Da Gama left Mozambique for India at the end of March, accompanied by a pilot lent by the sultan. In July 1500 Pedro Álvares Cabral, on his way to India, saw Sofala, and on his return it was visited by a squadron of his ships under Sancho de Toar, who made inquiries about its legendary gold trade. Between 1500 and 1502 either Cabral or João da Nova visited Lourenço Marques Bay. A Portuguese settlement was made at Sofala to exploit the fabled gold trade from the empire of Monomotapa (*q.v.*), which was centred in Rhodesia but extended into Mozambique. The Portuguese in 1507 occupied Mozambique Island to serve as a way station to India.

Attempts to reach the monomotapa were disappointing, though a convict named António Fernandes explored much of his territory before 1514. The Portuguese soon realized that they could not control the trade of the interior from Sofala alone, as Arab and Swahili merchants were making increasing use of the Zambezi route. Accordingly, after 1531 the Portuguese established settlements on the Zambezi banks at Sena and Tete, respectively 160 mi. (257 km.) and 260 mi. (418 km.) upstream. In 1544 a post was founded at Quelimane to guard the river delta. At the same period, the Portuguese began to trade at Inhambane and Lourenço Marques Bay, though no permanent settlement was set up at either place for some time. Portuguese efforts at Mozambique centred on the gold of the monomotapa; it was only there that they involved themselves seriously in African affairs. In 1561 the Jesuit Gonçalo da Silveira reached the head village of the monomotapa, whom he baptized. The Arabs and Swahili seeing their commercial position threatened by the Portuguese, convinced the chief that Silveira's intentions were evil, and he had the Jesuit strangled.

The death of Silveira was followed by the dispatch (1569) of an expedition from Lisbon to seize the monomotapa's mines. The expedition ended unsuccessfully in 1575, but despite this setback the Zambezi Valley and the monomotapa's country remained the focus of Portuguese attention until the late 19th century. Elsewhere, the Portuguese limited themselves, or were limited by African opposition, to scattered settlements along the coast. Nevertheless, the arrival of the Portuguese in East Africa had a vital impact on African trade to the north of the Zambezi.

Taking advantage of factional strife the Portuguese in 1629 negotiated a vassalage treaty with Monomotapa Mavura, who thereby recognized Portuguese sovereignty over his kingdom. Portuguese ascendancy was short-lived, however, and at the end of the 17th century the expansion of the Rozvi kingdom of Guruswa,

ruled by Changamire, eclipsed the power of both the monomotapa and the Portuguese to the south of the Zambezi.

In 1752 Mozambique, after being subordinated to the Portuguese administration at Goa in India, was separated and given an independent governor. In the 18th century the slave trade became an important factor in Mozambique for the first time. The demand came first from French slavers from the Mascarene Islands and later from the Brazilians. Slave trading by Europeans continued into the 1850s, and an active slave trade to Madagascar was carried on by Arabs and Swahili for several decades more.

Colonization.—Until the mid-19th century the most serious attempt to colonize Mozambique was the *prazo* system. This system of crown grant estates, which had its roots in the late 16th century, was formalized by the Portuguese government in the middle of the 17th. It failed as a colonization scheme, because the estate holders (*prazeros*) amassed large personal fiefdoms. In the 19th century a series of wars was waged by the government against these virtually autonomous rulers. A similar though less ambitious attempt was made to colonize the Kerimba Islands, which extend from Cape Delgado almost to Porto Amélia. There, too, the estate holders became independent lords.

No further colonization plans were contemplated until the 20th century. Several pilot projects failed in the 1930s and 1940s, but since the 1950s an attempt to settle immigrant Portuguese peasant cultivators, either in cooperatives or on small individual family holdings, has been pursued in the south. The most ambitious of these is centred in the lower Limpopo Valley, another is proposed for the upper reaches of the Revué River. The Mozambique government, unlike its counterpart in Angola, has kept to a minimum the influx of poor unskilled white immigrants.

Portugal v. Other European Powers in Africa.—At the beginning of the 17th century the Portuguese beat off three attempts by the Dutch to seize the port of Mozambique. The Austrians seized Lourenço Marques in 1777, but Portuguese sovereignty was reestablished in 1782. During the Napoleonic Wars the French attacked Lourenço Marques, Inhambane, Mozambique, and the Kerimba Islands. During the same period these islands suffered more seriously at the hands of Sakalava raiders from Madagascar.

In the 19th-century partition of Africa among the European powers, Portugal maintained rights based on the discovery of most of the African coast, in the face of the doctrine of effective occupation. Until the Berlin Conference (1884) Portugal hoped to preserve a continuous belt of territory from coast to coast, uniting modern Angola with Mozambique. The acquisition of British rights in the area frustrated this design. The Portuguese proposed to submit the question to arbitration, but Britain refused and delivered an ultimatum to Lisbon (1890). A treaty in 1891 defined the frontiers of British and Portuguese possessions.

Colonial Rule.—The establishment of effective colonial rule in the interior began in the 1890s and was not completed in the northwest until 1912, when the Yao chief Mataka was subdued. The Makombe Rebellion (1917), which embraced much of the country south of the Zambezi, was the last traditional manifestation of African opposition to Portuguese rule.

The Companhia de Moçambique was incorporated by royal charter in 1891 for a term of 50 years. Much of its capital was foreign, and it exercised sovereign rights over the territories of Manica and Sofala until they were entrusted to direct Portuguese administration in 1942. The Companhia do Niassa acquired a charter for the administration of lands north of the Lurio River in 1894. Development was comparatively slow, and in 1929 the Portuguese government took over administration of the area.

Under the Treaty of Versailles (1919) the German East African territory between the mouth of the Ruvuma River and Cape Delgado (the Kionga or Quionga triangle) was added to Mozambique.

Railway building led to a rapid expansion of Mozambique's economy, and conventions with the countries of the hinterland were signed covering the question of transit trade and the recruitment of Africans from Mozambique to work in the South African Rand mines. In 1901 a *modus vivendi* governing these matters was concluded with the Transvaal government. This was replaced by the Transvaal-Mozambique Convention in 1909, which lapsed

in 1923 and was replaced in 1934 by a new treaty which, ran until 1939; it was then prolonged for five years and later remained in force subject to 12 months' notice of termination by either party.

A measure of autonomy was granted to the colony under the Portuguese republic, and this was extended in 1920. After the Portuguese revolution of 1926 this system was brought to an end, and within the provisions of the Colonial Act (1930) a much more centralized system was adopted. Mozambique was designated an overseas province of Portugal in 1951.

African Nationalism.—In the 1960s various African nationalist parties were formed in exile. These were united as the Frente de Libertação de Moçambique (Frelimo; Mozambique Liberation Front) in 1962 under the presidency of Eduardo Mondlane, a former professor of anthropology at Syracuse (N.Y.) University. Fighting between Frelimo forces and Portuguese troops broke out in northern Mozambique on Sept. 25, 1964, the day celebrated as marking the beginning of the Mozambique people's struggle for freedom, and has continued. There are several small rival organizations, but only Frelimo is recognized by the Liberation Committee of the Organization of African Unity. (A. A. G. P.; E. A. A.)

ADMINISTRATION AND SOCIAL CONDITIONS

Administration.—Constitutionally, Mozambique is an integral province of Portugal; it has 7 representatives in the Portuguese National Assembly, elected on a restricted basis depending on Portuguese literacy and income. It is administered by a governor general who is appointed by the Council of Ministers in Lisbon and is directly responsible to the minister for overseas provinces. He is assisted by a Legislative Council, composed of 16 elected and 8 appointed members; and is advised by a Government Council composed of 12 members, including the secretary-general, the four provincial secretaries, the chief military commanders, the attorney general, the director of the treasury, and two elected members of the Legislative Council who are chosen by the governor-general. There is also an Economic Coordination Council which includes 11 representatives of the private sector. The few principal areas with European, half-caste, and *assimilados* majorities are designated as communes and have elected councils.

There is only one political party, the government's União Nacional (National Union).

Mozambique is divided into nine districts (*distritos*; see table), each administered by a governor. These are divided into *concelhos* (municipalities), subdivided into *freguesias* (parishes), and into *circunscrições* (circumscriptions, or rural subdistricts), sub-

the mid-19th century, and the numbers increased after the discovery of gold in 1886.

The ethics of Portuguese colonial theory demands labour of the African as a moral obligation. Africans are consequently recruited by licensed companies to work on contract for European-owned agricultural and industrial enterprises. Wages are very low, about Esc. 5 a day allowing for food and lodging. Contract employment averages about 300 days a year, the annual wage being about \$52.50 U.S., compared with about \$70 (Esc. 2,000) annual average earnings by Africans cultivating their own cotton. Wages are considerably higher in industry than in agriculture. Europeans are employed (chiefly in the higher grades) in commerce, the public services, communications, and transport. The Chinese and half-castes devote themselves to agriculture and commerce; most of the traders are Indians.

Development plans in hand, especially in the Revué, Limpopo, and Zambezi valleys, include the resettlement of Africans, construction of new villages, and improvement of living conditions.

Health.—Malaria and other diseases are prevalent, especially on the lower ground. Great progress has been achieved in making Lourenço Marques and the other main centres healthful, and medical and preventive services have been much extended, especially in combating malarial mosquitoes at their breeding grounds. Endemic focuses of sleeping sickness have been verified at various places, and tsetse fly is found in several districts. Schistosomiasis (bilharziasis) is widespread among the African population. There are three central hospitals (Lourenço Marques, Beira, Nampula), several regional hospitals, and about 500 smaller installations. Mozambique in the 1960s had one doctor to 20,000 inhabitants, one infirmary to 5,000, and 1.4 hospital beds to 1,000.

Education.—All instruction is given in Portuguese. Primary education of Africans, which normally lasts four or five years, is entrusted to the Roman Catholic missions, which run more than half of the primary schools with the help of a state subsidy. There are also about 2,500 pre-primary schools, almost all subsidized mission establishments. In 1961 there were six secondary and eight technical schools. About 400,000 children are in primary schools, compared with about 4,000 in secondary. While there is no university, and students usually go to Portugal for higher education, a program of general university studies was created in 1963, although it is confined to science, technology, and teacher training.

THE ECONOMY

Mozambique is one of the least developed parts of Africa. It can be divided into three economic zones. (1) The northern zone (Cabo Delgado, Niassa, and Moçambique districts), which is served by the port of Nacala and a developing railway to Lake Nyasa, is dominated by agriculture and has many Asian traders. (2) The central zone (Zambézia, Tete, and Manica e Sofala districts), with several railways leading from the hinterland to Beira, depends on transit trade. (3) The southern zone (Inhambane, Gaza, and Lourenço Marques districts) depends both on transit trade and on the migration of 150,000 Africans a year to the Rand mines. Lourenço Marques and Beira have developed industrially.

The development of the territory was greatly assisted by the transit trade of the Transvaal, Zambia, Malawi, and the Congo (Kinshasa), though this in some ways hindered the growth of internal communications. The hiring of African labourers to the Rand mines has also contributed much to the territory's prosperity, though the absence of so many workers affects its own agriculture. The requirements of the transit trade have led to a continuous development of the ports and railways, and the construction of railways into the interior has given rise to new townships in the hinterland of the capital and of Beira. Agricultural production has steadily increased, and Portuguese industrialists have introduced a number of manufactures. British and South African interests are represented in transport services, distribution, and agriculture, and United States, French, Belgian, and West German capital has also been invested in the territory.

Agriculture.—Though about a third of the country is suitable for agriculture, only about 1% is actually cultivated. A number of important European companies produce sugar (approaching

Administrative Divisions of Mozambique

Districts and capitals	Area (sq.mi.)	Population		
		1950 census	1960 census	Density (1960; per sq.mi.)
Cabo Delgado (Porto Amélia)	30,313	494,974	542,165	17.9
Gaza (Vila de João Bela)	33,750	681,602	675,150	20.0
Inhambane (Inhambane)	25,589	571,625	583,772	22.8
Lourenço Marques (Lourenço Marques)	4,009	199,067	441,363	110.1
Manica e Sofala (Beira)	52,268	711,584	781,070	14.9
Moçambique (Nampula)	30,815	1,317,631	1,444,555	46.9
Niassa (Vila Cabral)	46,242	260,413	276,810	6.0
Tete (Tete)	36,041	337,656	470,100	13.0
Zambézia (Quelimane)	38,819	1,164,359	1,363,619	35.1
Total	297,846	5,738,911	6,578,604	22.1

divided into *postos administrativos* (rural administrative posts).

A judicial system, comprising a court of appeals and courts of preliminary investigation in ten judicial divisions, maintains separate sections for African cases and applies the Portuguese law.

Mozambique is a military command of overseas Portugal. Military and naval headquarters are at Lourenço Marques, which is also the headquarters of one of Portugal's air regions.

Living Conditions.—Of the total working population of about 1,600,000, three-quarters are employed in agriculture and about one-tenth in industry; at least another one-tenth work in neighbouring countries (although some estimates go as high as 450,000 migrant labourers), especially in the Rand mines. Workers first went to South Africa when diamonds were discovered at Kimberley in

200,000 tons in the 1960s) and bagasse, tea (8,000 tons), sisal (30,000 tons), copra (60,000 tons), and vegetable oils (15,000 tons), all mostly for export. Sugar is cultivated in the Zambezi, Buzi, and Komati (Incomati) valleys and around Inhambane; tea near Milange and Guruê; sisal near Quelimane and Nampula, and in the districts of Cabo Delgado, Inhambane, and Manica e Sofala; and coconuts between the mouth of the Zambezi and Mogincual Bay (south of Mozambique).

African agriculture is chiefly subsistence, the main crops being corn (maize), peas, peanuts, manioc, sesame, and vegetables. Among cash crops, Africans account for virtually all the production of cotton, which is the territory's chief export (around 40,000 tons annually; though, as an indication of the province's underdevelopment, it ranks only fifth among African countries in cotton exports). Africans also account for nearly all the rice (30,000 tons husked), which meets local needs and leaves a surplus for export; and cashew nuts (119,000 tons of unprepared nuts), which are uncultivated but also an important export. Both cotton (around Beira, and in Quelimane and Niassa) and rice are cultivated under European supervision, under a concessionary system. Between 1940 and the mid-1950s the productivity per acre of cotton was trebled. There are great possibilities for the expansion of rice growing, nearly half the territory being suitable for it.

In contrast to Angola, there are no white small farmers except on the Chimoio Plateau, where they cultivate tobacco, citrus fruit, wheat, oilseeds, and a little cotton. In the early 1960s, after irrigation had begun in the Limpopo Valley, settlement of several thousand families from Portugal was started there. Encouraging results had already been achieved in the valley with long-staple cotton and wheat. It was hoped to follow this experiment with the settling of the large, rich basin of the Revué River (west of Beira).

Animal husbandry is little developed, and the Africans typically own no cattle. The province has about 1,000,000 oxen, 400,000 goats, 100,000 sheep, and 100,000 pigs.

Forestry.—Though exports of timber and wood products have expanded greatly beyond what they were before World War II, the potentialities for forestry are still far greater, particularly behind Beira. (See also *Vegetation*, above.)

Mining.—The mineral resources of the province are still inadequately known, though the Mines Department started a full survey in the mid-1950s. A little gold is mined near Vila de Manica and Tete, and there are alluvial deposits near Vila de Manica and Alto Ligonha (Zambézia). Coal is the only mineral produced in other than negligible quantities, more than 250,000 tons being taken annually from the Moatize field in the Zambezi Valley near Tete. Coal resources there are estimated at 700,000,000 tons, and coal has also been discovered near the Limpopo Railway and in the Nyasa Basin. The Companhia Carbonífera de Moçambique, with Belgian capital, supplies the railway and the port of Beira and exports some coal to Malawi, although coal is also imported from South Africa. Iron ore exists at Moatize near the coal mines. The Alto Ligonha Company, with exclusive rights over part of Zambézia, mines beryl, mica, columbite, and bismuth. Quantities of graphite exist near Nacala and in Angónia, but extraction is irregular. Radioactive minerals exist in the Tete and Moçambique districts; prospecting concessions for these are granted only through the Portuguese government. Prospecting for petroleum had yielded no positive results by the later 1960s, except at Pande, 160 mi. SW of Beira. Diamonds were found for the first time in 1966, near the Rhodesian border.

Fisheries.—The Mozambique coast is very rich in shellfish and certain fish. A large fish-processing plant was established at Porto Amélia and five subsidiary plants were being built along the coast to act as feeders. The Anglo American Corporation of South Africa was reported in the late 1960s to be planning large investments in the fishing industry. There was also great hope for developing this industry in the inland waters.

Power.—Industry obtains most of its energy from thermal power stations, using imported fuel, and only about one-fifth of its supply comes from hydroelectric plants. However, the centre of the country obtains much of its power from the Mavúdzi Dam at the Revué Falls on the Revué River, from which the government

has also undertaken to supply power to Umtali, in Rhodesia. Other development works include a dam at Chicamba Real Gorge, also on the Revué River near Mavúdzi, and on the Limpopo and Komati rivers and on the Zambezi, all of which involve agricultural development as well as power supply.

Manufacturing.—Less than one-tenth of the working population is employed in manufacturing industries, chiefly in Beira and Lourenço Marques. The largest numbers work in sugar, sisal, cotton, and tea factories, but there are also tobacco, oil, and soap factories, potteries, flour mills, and cement works.

Finance and Trade.—The chief sources of revenue are customs duties, income tax, and license and stamp duties. There was a surplus of income over expenditure after 1937, so that large sums were devoted to public works.

The monetary unit is the Mozambique escudo of 100 centavos, equal in value to the Portuguese escudo (about Esc. 80.20 = £1 sterling; Esc. 28.75 = \$1 U.S. or Esc. 1 = about 3.5 cents).

Imports in 1963 totaled Esc. 4,077,000,000 and exports Esc. 2,896,000,000. Re-exports, largely minerals from South Africa, were valued at Esc. 6,000,000,000 annually in the early 1960s and transit traffic at Esc. 8,000,000,000. Portugal accounts for about 30% of imports and about 35% of exports. South Africa supplies around 12% of imports, and the U.K., West Germany, and the U.S. are also important trading partners, while India and Rhodesia are important customers. The chief imports are cotton textiles, railway equipment, agricultural and other machinery, iron and steel, and table wines. (For exports see *Agriculture*, above.)

Transport and Communications.—The road system is satisfactory in the settled areas, though many parts of the territory are still inaccessible by road, and much surfacing and bridge building is necessary to make the existing roads suitable for use all the year round. Of 15,000 mi. (about 24,000 km.) of fully constructed road in the province in the 1960s, 6,500 mi. (10,500 km.) were described as main roads, 2,300 mi. (3,700 km.) being first class. Metalled roads are limited to the capital and Beira, but the chief towns are linked by good gravel roads. The main international routes run from Lourenço Marques to Swaziland and to Johannesburg, S.Af., from Beira to Salisbury, Rhodesia; from Tete to Blantyre, Malawi, and Fort Jameson, Zambia; from Quelimane, Lumbo, and Nacala to Blantyre; and a smaller coastal road north to Tanzania.

The railway system owes its existence to the transit trade, but there is still little rail connection between the chief centres of the territory itself. The total internal length is about 2,000 mi. (3,300 km.), mostly state owned. There are lines from Lourenço Marques to Johannesburg and to Bulawayo, Rhodesia. The port of Beira is connected with Blantyre and Salisbury. A railroad running from Lumbo is intended to reach Lake Nyasa.

The province is served by about 40 shipping lines, which link Lourenço Marques with the main South and East African, European, Indian, and U.S. ports. Coastal shipping also uses harbours at Quelimane, Inhambane, Chinde, Mozambique, António Enes, Porto Amélia, and Nacala. Lourenço Marques is possibly the best shelter on the East African coast between Suez and Cape Town, and improvements are in progress there and at the ports of Beira, Quelimane, Nacala, and Porto Amélia. In 1962, 7,093,316 tons of goods were transported through Lourenço Marques, and 3,085,592 tons through Beira.

An oil pipeline runs from Beira to Umtali, in Rhodesia. In April 1966 considerable British diplomatic pressure was brought to bear on the Portuguese not to permit oil to be piped through this line to the rebel regime in Rhodesia (*q.v.*). At the same time, a British naval patrol was mounted to intercept any vessels intending to discharge oil for Rhodesia at Beira. In December, responding to the UN Security Council resolution imposing economic sanctions, including oil imports, on Rhodesia, Portugal announced that it did not mean to supply oil to Rhodesia but that it would not attempt to control such provisions to Rhodesia. The interests of the Portuguese in Mozambique, however, clearly lay in maintaining white rule in Rhodesia, and the traditional policy of good neighbourliness continued. The Zambezi is navigable by light-draft steamers throughout its course in Mozambique, with a break at the long

Quebrabasa Rapids above Tete. (See also ZAMBEZI.) There is a direct steamer and railway connection with Lake Nyasa via the Shire River.

There are regular air services from Lourenço Marques to Mocimboa de Praia in the north and to Tete, and international services to Johannesburg, Salisbury, and Durban. The airports at Beira and Nampula also handle international traffic. Most local services are operated by the Directorate of Harbours, Railways, and Transport, but private companies operate air taxi services.

The province is connected with Europe by telegraph via South Africa and via Zanzibar. A cable connects Mozambique with Madagascar and is linked with the Aden-Durban cable. There are land lines between Lourenço Marques and Johannesburg and between Beira and Salisbury, an internal radio system for communication between the main centres, and an external radio system for communication with Portugal. The Radio Clube de Moçambique at Lourenço Marques (which controls several transmitters) is the official broadcasting agency, and Emissôa de Aero Clube (commercial) and Radio Pax (religious) are privately owned.

PORTUGUESE GUINEA (GUINÉ PORTUGUESA), a Portuguese overseas province on the West African coast, extends from Cape Roxo to the Cajet estuary (the western arm of the Cogan estuary) at Tristão Island, being enclosed inland by the republics of Senegal and Guinea. Its area is 13,948 sq.mi. (36,125 sq.km.). The capital is Bissau.

Physical Characteristics.—A line along the Geba Valley to its junction with the Corubal River, and from there to the extreme south, separates the two main geological features of the territory: to the west the sediments of the Tertiary Gulf of Senegal and to the east the Paleozoic formations of Fouta Djallon. Almost the whole country is lowland, with many swamps and pools, the only high ground being in the southeast (about 800 ft. [244 m.]). The main rivers are the Cacheu, Mansôa, Geba, and Corubal (Rio Grande), the last two uniting in a large estuary. The coast is heavily indented by deep inlets, or gulfs, including the Rio Tombali, Rio Grande de Bolola, and Rio Cacine. Off the coast many islands are separated from the mainland only by creeks, although the Bijagós (Bissagos) Islands, of which there are about 25, lie up to 30 mi. (48 km.) offshore.

Climate.—During the dry season, December-May, the hot

northerly harmattan (q.v.) blows from the desert. The maximum monthly mean temperature is 85° F (29.5° C) in May and the minimum 77° F (25° C) in January. The whole rainfall (average 75 in. [191 cm.]) occurs in the wet season, June-November, one-third of it in August.

Vegetation and Animal Life.—The coastal region and the islands are covered with forests and palm trees, the valleys being swampy and the coasts and gulfs bordered by mangroves. The rest of the country, interspersed with swamps, is less forested. The chief trees are the cotton tree, the African mahogany (*Khaya senegalensis*), the côpaiba balsam tree, the baobab, and many varieties of acacia. Fruit trees include the pawpaw, guava, mango, banana, and orange. The fauna includes water buffaloes, deer, antelopes, leopards, monkeys, many varieties of snakes, and in the south a few elephants. Crocodiles and sharks abound in the estuaries. Birds include the pelican, heron, marabou, trumpet bird, egret, and several parrots.

History.—Portuguese Guinea was first discovered in 1446 when an expedition led by Álvaro Fernandes reached the most northerly part of its coastline. In the following decade various expeditions, notably those of the Italian Alvise Ca da Mosto and the Portuguese Diogo Gomes, advanced as far as the mouth of the Geba River. The remainder of the coast was explored by Pedro de Sintra in 1460. The colonists of Santiago in the Cape Verde Islands were later granted trading rights in Guinea, but the only settlers seem to have been isolated traders living among the natives. In the middle of the 16th century, foreign interlopers began trading in Guinea: by 1588 the Cape Verdeans had established a village at Cacheu, and in 1624 the Overseas Council sent royal officials there and to other parts with instructions to administer and defend them. Some of the early settlements, such as São Felipe and Porto da Cruz, were later abandoned, but others still exist, among them Farim, Geba, and Buba. With the Portuguese restoration of 1640, a captain-major and factor was appointed to Cacheu from Lisbon, and the old dependency on the Cape Verde Islands gradually declined, till in 1879 all formal connection with Guinea ceased. In 1676 the Cacheu Company was given a virtual monopoly of the Guinea trade, but it was soon dissolved.

Reacting to the expansion of the French Senegal Company, the Portuguese built a settlement at Bissau in 1687, and this was created a captaincy in 1692, the duty of maintaining it being transmitted to the second Cacheu Company. The main export of Guinea was slaves for Spanish America, and the second Cacheu Company won the Spanish *asiento*, or monopoly, from the French Senegal Company. However, the company's contract was terminated at the beginning of the 18th century, and Bissau was abandoned to be refounded in the 1750s under the influence of the Marquês de Pombal's Graô-Pará Company. In 1792 an English expedition led by Lieut. Philip Beaver tried unsuccessfully to establish a settlement at Bolama. This attempt led to a dispute between Portugal and Great Britain about the possession of Bolama, which was finally awarded to Portugal by the arbitration of Pres. Ulysses S. Grant of the United States (April 21, 1870). In 1879 Bolama was made the capital of the colony. The Franco-Portuguese frontier was defined in 1886, when the Portuguese lost the southern bank of the Casamance estuary in the north in return for the Cacine District in the south. The demarcation was completed in 1902-05.

Until the 19th century the colony had been dependent on the slave trade and unable because of it to attain orderly development. It was only after its abolition that the Portuguese were able to subdue the interior (1890-1915). Even after this there was some resistance by the Bissagos, but from 1936 the colony developed steadily and peacefully. Bissau was restored as capital in 1942. A number of important reforms were carried out in 1961, including the granting of citizenship to all inhabitants by the revocation of the *estatuto dos indígenas*. From 1962 the hitherto tranquil province became disturbed by acts of terrorism and guerrilla fighting.

(H. V. L.; A. T. DA M.)

Population.—The population in 1960 was 521,336. The population at the 1950 census was 510,777, including 503,395 Africans, 4,568 half-castes, and 2,263 Europeans. The half-castes

PRINCIPAL COMMUNITIES AND RIVERS OF PORTUGUESE GUINEA

include many creoles from the Cape Verde Islands who act as minor officials and storekeepers. The Africans can be divided into three groups of tribes. The first group is Muslim, each tribe with its own language, and includes the Fula or Fulani (*q.v.*), who are seminomadic and raise cattle, and the sedentary Mandingo (*q.v.*). The second group (about 60% of the population), including the numerous Balante, are pagan and have various dialects though some of the sub-groups share a common language. They are sedentary cultivators on the coastal strip and as such are dispersed. They breed cattle and sacrifice them at important funerals. Both these groups have a patriarchal organization and are moderately polygamous with a regime of leviratic marriages. The third group consists of several small tribes, all originally from adjacent areas but now dispersed, and mostly Muslim.

A Cape Verde-Guinea Creole dialect is the *lingua franca*. Portuguese is the official language.

The chief towns are Cacheu, Bolama, Bafatá, Bissau, and Mansôa. (Ao. Ca.)

Administration and Social Conditions.—According to the revised Portuguese constitution (1951), Portuguese Guinea is an integral part of Portugal. It is designated as an overseas province and is represented in the National Assembly in Lisbon by one member. Executive and legislative functions are carried out by the governor who is responsible to the Portuguese minister for overseas territories. He is assisted by a government council of ten members. The province in the mid-1960s was divided administratively into nine *concelhos* (municipalities), subdivided into urban *freguesias* (parishes), and three *circunscrições* (circumscriptions), subdivided into rural *postos administrativos* (administrative posts). Native administration is left to dependable tribal chiefs. There is a tribunal of justice under the judicial district of Lisbon.

The native Africans who own most of the land are chiefly occupied in cultivation of staple crops for subsistence and export. Several thousand urbanized Africans live in the towns. There are 11 hospitals and a number of health and maternity centres. There is also an organization to combat endemic diseases (sleeping sickness, leprosy, etc.) which has substantially reduced the incidence of these diseases.

Education is provided both by the missions and by the state. There are more than 200 primary schools and a number of rudimentary schools. There are also Koranic schools for Muslims.

The Economy.—The development of the economy, which is agricultural, has been gradual. The chief products are native crops such as peanuts (about 45,000 tons annually), palm nuts (15,000 tons), palm oil (1,000 tons), and rice (60,000 tons). Other products are hides, wax, and timber (10,000 tons). Cattle, pigs, and goats are raised, and there is palm-oil processing, rice milling, and pottery manufacture. Trade is largely with Portugal. In the early 1960s exports (chiefly peanuts, palm oil, nuts, and timber) were valued at about 200,000,000 escudos annually, and imports (cotton piece goods, wines, foodstuffs, equipment) at more than 250,000,000 escudos.

The currency is the Portuguese overseas escudo, the bank of issue being the Banco Nacional Ultramarino.

Bissau is the leading port, followed by Farim (Binta) on the Cacheu River and Bolama on Bolama Island. The deep estuaries provide easy communication with parts of the interior, and there are about 2,000 mi. of roads but no railways. There are about 30 local airfields for light planes and one international airport (Bissau). The government-controlled radio station, Emissora da Guiné, transmits regularly in Portuguese and African languages.

PORTUGUESE INDIA (ESTADO DA ÍNDIA), a name once used for those parts of India which were under Portuguese rule from 1505 (Goa 1510) to December 1961. It consisted of several isolated tracts: (1) the territory of Goa with the capital, a con-

siderable area in the middle of the west coast of India; (2) Damão or Daman, with the separated territories of Dadra and Nagar Aveli (Nagar Havili), north of Bombay and lying between the Indian states of Maharashtra and Gujarat; (3) Diu with Pani Kota Island on the southern coast of Kathiawar Peninsula in Gujarat State. The total area was 1,619 sq.mi. (4,193 sq.km.) and the population in 1960 was 625,831. Of this total Goa accounted for 1,394 sq.mi. (3,610 sq.km.) with 589,120 persons. About 60% of the total inhabitants are Hindus, about 37% Christians, and the rest are Muslims. The whole formed a single administrative province under a governor general and a single ecclesiastical province subject to the archbishop of Goa who is also Primate of the East.

History.—For almost a century (1500–1600) the Portuguese had a monopoly of European exploration and trade in the Indian Ocean. Their interests on the west coast of India were largely determined by sailing conditions; in Goa they found a defensible island site with excellent harbour facilities on either side and, captured by Afonso de Albuquerque in 1510, it became the main Portuguese base, which it remained for four and a half centuries. With the end of the British raj in India in 1947, and the quiet handing over of former French settlements in 1949–54 (see INDIA, FRENCH), there was a natural desire of the Republic of India to absorb the Portuguese territories also. The position, however, was somewhat different. Four and a half centuries marked by much intermarriage and under the influence of the Catholic Church produced a distinctive racial, cultural, religious, and linguistic group, especially in Old Goa itself, which was not yet ready to throw in its lot with India. However, India's continuous demand for the cession of the Portuguese territories and Portugal's unwillingness to negotiate led to India's taking Goa, Damão, and Diu by force, Portuguese resistance ceasing on Dec. 19, 1961. The territories, constituted as the Union Territory of Goa, Daman, and Diu, are centrally administered by the government of India.

Economy.—The evaporation of seawater to produce salt is an industry in all three territories. Since its discovery in 1906 there has been a considerable production and export of manganese ore from deposits near Mormugão. Otherwise the economy depends largely on the transit trade of Mormugão from which there is an export of iron pyrites, manganese ore, coconuts and copra, fresh and dried fish, spices, cashew nuts, and salt. Remittances home from the many Goanese resident abroad played a large part in the colony's finances.

See also GOA; DAMÃO; DIU.

(L. D. S.)
PORTUGUESE LANGUAGE, one of the Romance languages (*q.v.*), is the language of Portugal, including the Madeiran and Azorean archipelagos, and of Brazil. It is also the official language of Portugal's overseas provinces in Africa and the east. Spoken by about 70,000,000 persons, it is the end product of the evolution of the Romance dialect that was spoken in the county of Portugal, awarded by the king of León and Castile at the end of the 11th century to Count Henry of Burgundy. Henry's son became the first king of an independent Portugal and advanced the area of his rule southward at the expense of the Muslim Moors who then governed the region. The language spoken by the Portuguese displaced the Mozarabic presumably spoken by Christians or their descendants who were living under Moorish domination; displaced, the Mozarabic undoubtedly influenced the emerging Portuguese to such an extent that the new national language is perhaps better considered the resultant of a Portuguese force from the northwest and a Mozarabic force from the south. By the middle of the 13th century Portugal had attained boundaries that are substantially those of the present day, and Portuguese became the language of the entire country. There is slight dialectal differentiation. Except for an occasional border dialect on the Spanish frontier, however, the *fares regionais portuguesas*, as they are now called, are mutually comprehensible. The language of the nation's capital, Lisbon, and of the ancient university city, Coimbra, has provided the basis of the standard national language. Portuguese was first written at the end of the 12th century. A standard written language was quickly formulated. It has changed little since the 13th century, virtually not at all since the 16th.

Portuguese was established as the official language of Brazil soon after Pedro Álvares Cabral's discovery of the continent in 1500. In its subsequent development it proved to be, on the whole, more conservative than the language of Portugal. Although regional pronunciations have developed, they do not hinder intercommunication. Moreover, the Brazilians and Portuguese communicate with ease despite an instantly recognizable accent. The influence on the Portuguese of Brazil of native American languages, African languages of imported slaves and Spanish of adjacent countries to the south has probably been negligible except for certain items of vocabulary.

Vasco da Gama initiated the Portuguese influence in the orient. The language of the Portuguese discoverers, colonizers, merchants and missionaries spread rapidly and Portuguese words are today far more disseminated than the area of Portugal's political control would suggest. They are found on Ceylon, for example, and even in Japan. Thus in the latter country the Portuguese *têm-poras* "Ember days" is used for fried seafood.

In its evolution since the establishment of the Portuguese monarchy, Portuguese has developed more or less independently of the Romance dialects that ultimately became the language of Spain. In Galicia, however, the local dialect was originally very similar to Portuguese and has occasionally been used as a literary language. Several features of Portuguese distinguish it markedly not only from Spanish but also from other Romance languages.

Phonology.—There are five distinctive nasal vowels, as in *sim*, *lenço*, *sã* and *lanço*, *som* and *dom*, and *dum*, and a series of nasal diphthongs, as in *pão*, *põe* and *bem*. Final *em*, as in the latter word, is pronounced [ẽ] in standard Portuguese but as [ē] in many regions of Portugal and in Brazil. Among the oral vowels the distinction between closed and open *e* and *o* is meaningful: *sê-sê*, *pôde-pode*, the circumflex indicating closeness, the acute accent openness. Final unstressed vowels are weak and tend to disappear, especially in Portugal. In most regions *s* before a consonant is [ʃ] or [ʒ], depending on whether the consonant is voiceless or voiced (*casta, Lisboa*); intervocalic *s* is [z]. In the Rio de Janeiro area *t* and *d* before [i] become affricates approaching [tʃ] and [dʒ]. Historically, Latin intervocalic *l* and *n* have in many situations disappeared (*sô*, Spanish *solo*; *lua*, Sp. *luna*). Because of the history of *l* and *ll*, the Portuguese definite article is simply *o*, *a*, *os* or *as*. Although the intervocalic *n* tended to disappear as a consonant, it often nasalized a preceding vowel. Thus, the singular noun ending *ão*, as in *mão*, *alemão*, *nação*, corresponds to three plural endings, *mãos*, *alemanes*, *nações*. Comparison with Sp. *manos*, *alemanes*, *naciones* clarifies the endings and confirms that today's *ão* represents a convergence of earlier *ão*, *am* and *om*. Latin stressed *e* and *o* did not diphthongize (*pê*, *terra*, *roda*, *porta*, contrasted with Sp. *pie*, *tierra*, *rueda*, *puerta*), nor has initial *f* disappeared (*filho*, Sp. *hijo*).

Forms.—Portuguese is most different from Spanish in the verb system. It retains the Latin pluperfect as a pluperfect (1st and 3rd sg. *cantara*, used alternatively with a compound *tinha cantado*). It has a conjugated or personal infinitive and a future subjunctive. They have identical endings, those of the former being added to the infinitive, those of the latter to the preterite stem (3rd pl. *cantarem*, but *fizerem-fizerem*). Portuguese has two forms for "two," masc. *dois* and fem. *duas*, and maintains vowel harmony in such groups of words as demonstrative *isto*, a neuter pronoun, and *este* and *esta*, masculine and feminine demonstrative adjectives, respectively, the *e* of *esta* being [ɛ].

Syntax.—As suggested above, *ter* (Lat. *tenere*) is today the normal verbal auxiliary, and not *haver* (Lat. *habere*). Object pronouns are normally placed after the verb in Portugal, although in spoken Brazilian they usually precede. In the future tense, today used chiefly in the written language, they are inserted between infinitive and ending (*dar-lhe-ei o livro* "I shall give the book to him"). The combination of preposition and article is common (*do*, *da*, *dos*, *das*, for *de + o*, etc., and similarly *no*, *em + o*, and *pelo*, *por + o*). Forms of direct address are elaborate, ranging from V.^a Ex.^a (*Vossa Excelência*) through *o Senhor* and *a Senhora* and a more familiar *Você* to *tu*; all but the latter take the so-called "third-person" verb forms. In Brazil V.^a Ex.^a

is restricted to the most formal discourse, its use otherwise being considered distinctly Portuguese.

Vocabulary.—An outstanding feature of Portuguese is the use of the church's designations for the days of the week, Monday *segunda-feira*, Tuesday *terça-feira*, Wednesday *quarta-feira*, Thursday *quinta-feira* and Friday *sexta-feira*. Saturday and Sunday are the common *sábado* and *domingo*. Portuguese shares with Spanish many words of Arabic origin, yet also has several not found in standard Spanish, such as *alface* "lettuce," *alfaiate* "tailor." The language of Brazil contains many words, particularly designations for native animals, flowers, foods and the like, that have not entered the language of Portugal or other Romance languages.

PORTUGUESE LITERATURE. The literature of Portugal is distinguished by a wealth and variety of lyric poetry, which has characterized it from the beginning; by its medieval lack of and later achievement in the national epic; by its wealth of historical writing; and by its relative slightness in drama, biography, and the essay. The early *cancioneiros* evidence a school of love poetry which spread, with the language, to Spain at a time when Spanish was as yet undeveloped for lyrical purposes. The *romanceiro* or balladry on the other hand was much influenced by that of Spain, though not sharing the latter's predilection for the heroic. *Amadís de Gaula* (q.v.), prototype of the romance of chivalry, was in its primitive version almost certainly Portuguese, as was, later, the *Diana* of Jorge de Montemôr (Montemayor), the masterpiece of the pastoral novel (see below; see also PASTORAL; ROMANCE). The *Lusíadas*, by Camões, may be held at once the most successful of the many Renaissance epics cast in the classical mold and the most national of great poems in any modern literature, and the many outstanding works of history and travel of the 16th and 17th centuries are worthy of a race of explorers who carried their flag, their faith, and their speech to the ends of the earth. Though Gil Vicente, in the early 16th century, was a dramatist of great gifts, no other appeared until Almeida Garrett in the 19th, and Portugal never developed a national drama.

This literature, which until the 19th century lay largely unstudied and unknown, has from the beginning been much exposed to foreign influences. The earliest was Provençal, and Provençal taste ruled for more than a century. Then came Castilian, with a court poetry which provided models until the Renaissance saw the triumph of that of Italy and the classics of antiquity. In the 17th century with political domination Spain again imposed its literary standards, followed in the 18th century by France. The Romantic movement reached Portugal from both France and England, two countries whose influence, joined in a lesser degree by that of Germany, persisted long after. The closeness of contacts with Spain, reinforced by dynastic marriages which often brought to the court at Lisbon a predominantly Spanish atmosphere, explains why for two centuries and more after 1450 nearly every Portuguese writer of note was bilingual and wrote also in Spanish, so that some, like

Montemôr and Manuel de Melo, are numbered among the classics too of Spanish letters. Portuguese literature retains nonetheless a distinct individuality which contrasts strikingly with that of Spain alike in the nature of its development and in the divergent kinds where lie its major achievements; in it may be seen reflected the differing ethnical constitution of its people and the distinctive paths along which their lot has been cast. The medieval lyric, the chronicles of Fernão Lopes, the plays of Gil Vicente, the *História trágico-marítima*, the bucolic verse and prose of the 16th century and, above all, the *Lusíadas*, are several expressions of a clearly defined national temperament which early carved out for itself original expression. (See also PROVENÇAL LITERATURE; SPANISH LITERATURE; FRENCH LITERATURE.)

Early Period.—Though no literary documents belonging to the first century of Portugal's history as a nation have survived, there is evidence of the existence of an indigenous popular poetry both sacred and profane. Provençal influences were for long to mold the manifestations of poetical talent, but they did not originate them. A few compositions from before 1200 survive; one, attributed to Sancho I (1185–1211), is the earliest extant *cossante*, the name now given to brief lyrical poems which are almost immobile in their repetitiveness and are marked by a wistful sadness which is never wholly absent from Portuguese literature. The accession in 1248 of Afonso (Alphonso) III, who had lived 13 years in France and returned home, bringing poets in his train, to play the role of patron of letters, inaugurated a period of poetic activity illustrated in the *Cancioneiro da Ajuda*, the oldest collection of Peninsular verse. Soon all the norms of Provence and of northern France were current, subtlety of form and device taking precedence in them over thought or emotion. Three main types of *cantiga* were recognized, all often practised by the same poet: *de amor*, *de amigo*, and *de maldizer*. The second, put into the mouth of the lady lamenting her lover's absence, commonly betrays a truer feeling than the first; in the third the poet vents satire on his rival or enemy.

The apogee of this palace poetry dates from the early years of the reign of Afonso's son Diniz (Denis; 1279–1325), who had been educated by a Frenchman, Aymeric of Cahors. Diniz, grandson and imitator in his services to culture of Alfonso the Learned of Castile, founded his country's first university in Lisbon (later removed to Coimbra) in 1290 and stimulated the translation into Portuguese of outstanding works from Spanish, Latin, and Arabic. He thus ranks as the founder of vernacular prose in Portugal; but he was also a true poet, technically accomplished and with genuine feeling, and was esteemed the best poet of his age in the Peninsula. To his court came troubadours and *jograis* from León, Castile, and distant Aragon to enjoy the last afterglow of a cult already dying or dead elsewhere, and about 2,000 poems by its 200 poets are preserved in the three great *Cancioneiros da Ajuda*, *da Vaticana*, and *Colocci-Brancuti* (or *da Biblioteca Nacional*). In the main this poetry forms monotonous reading today, because of its poverty of ideas and conventionality of metrical form and expression; in it poets served an apprenticeship to their craft, and the language developed its rare musical qualities against the birth of more individual inspiration.

In contrast with the restricted horizons of courtly verse, themes of adventure, war, and chivalry mingled with love, religion, and the sea in the considerable collection of ballad poetry known as the *romanceiro*. Differing in subject matter from the ballad in Spain, which drew heavily on the native epic tradition, the *romanceiro* still derived in all probability from across the border and exploited the popularity of the form—the octosyllable with assonance in alternate lines—in more congenial directions. Few if any of these romances can be dated earlier than the 15th century; they belong to the close of the Middle Ages, an anonymous collective poetry kept alive by oral transmission, with a late artificial flowering, from the pens of known poets, in the 16th and 17th centuries. Heroes and incidents of the French and Spanish epics were reflected in numerous derivative ballads: of native Portuguese epic we can point at most to a *Poema da batalha do Salado* (1340) by one Alphonso Giraldes concerning which the brief surviving fragment allows no firm inferences.

Prose literature took much longer than verse to perfect its instrument. Religious writings (fragments of the Bible, lives of saints, and monastic rules), brief annals of the early kings, and *livros de linhagens*, or books of descent, constitute the earliest texts; they date from the late 12th century onward and interest the student of language rather than of literature. The *Livro de linhagens* of Pedro, count of Barcelos (1289–1350), raised the last-named kind to the height of literature, and therein constitutes a landmark, by a concern that went beyond genealogy to history and legend. The early popularity of the *matière de Bretagne* is attested both here and elsewhere, as in the five songs based on Breton *lais* with which the *Cancioneiro Colocci-Brancuti* opens: the ideals of chivalry and the spirit of sentimental adventure associated with the knights of the Round Table clearly made strong appeal to the Portuguese temperament. The *História dos cavaleiros da Mesa Redonda e da demanda do Santo Graal*, an adaptation from the French dating from the early 14th century, is the chief relic of a considerable activity in this field, out of which derived *Amadís de Gaula*, progenitor of a long succession of romances of chivalry in Spain and Portugal. While the authorship and country of this are still in debate, the balance of probability inclines to a Portuguese original, at least for the first three books of c. 1350, from the pen possibly of one Vasco de Lobeira.

The 15th Century.—Under John (João) I (1385–1433), founder of the new dynasty of Avis, the court became once again a centre of literary culture. The king himself wrote a *Livro da montaria*, or treatise on the chase. His son Edward (Duarte) collected a rich library of the ancients (some translated by his order, as was also John Gower's *Confessio amantis*), and of medieval poems and histories, and composed a moral treatise, *Leal Conselheiro*, c. 1430, which revealed a great and conscious stylist. His brother Pedro's *Tratado da Virtuosa Benfeitoria* was a version of Seneca's *De beneficiis*; Cicero and Vegetius were among other authors translated by this much-traveled prince or at his instance. But the great distinction of the age was its chronicles, for which much credit falls to Edward who as king created in 1434 the office of Cronista Mor do Reino and appointed to it Fernão Lopes (*q.v.*), the father of Portuguese historiography—Robert Southey called him the best chronicler of any age or nation—and author of chronicles of the first ten kings of Portugal, of which only those of Peter (Pedro) I, Ferdinand (Fernando) I, and John I survive. Earlier he had, perhaps, written the biography of the hero of Aljubarrota, the constable Nuno Álvares Pereira. Vividness of style and character portrayal combined with serious documentation and a high sense of principle and responsibility to produce in Lopes the finest achievement of medieval Portuguese prose.

His successor in office, Gomes Eanes de Zurara (*q.v.*), adding to the seriousness a constant parade of erudition, continued the chronicle of John I on a lower level of artistry with an account of the 1415 expedition to Ceuta and the early period of expansion in North Africa. His chief work, born of admiration for Prince Henry the Navigator, was his *Crónica do descobrimento e conquista da Guiné*. Rui de Pina (c. 1440–c. 1523), if likewise not of the stature of Lopes either as historian or as artist, was free from the rhetorical defects of Zurara, and his chronicles of Duarte, Afonso V, and John II were characterized by a notable frankness: the people, who in Lopes had occupied the foreground, here yielded pride of place to the monarch. To Pina's reworking of Lopes' narratives of the six reigns from Sancho I to Afonso IV is owed the irreparable loss of the original text; his own chronicle of John II was in its turn reworked, and spiced with much anecdotal gossip, by Garcia de Resende (*q.v.*).

Poetry had suffered a long eclipse after the spate of activity reflected in the *cancioneiros*, and when in the mid-15th century it was once more cultivated, much had changed. The dominant influence came now from Spain, and where once Spanish poets had written in Galician-Portuguese, Portuguese poets initiated the long chapter of fealty, in theme and language alike, to Spain. Apart from the romances, popular poetry had disappeared along with that of the troubadours, whose legacy stood reduced to a set of metrical devices and another of conceits on the topic of courtly love (*q.v.*). The constable Dom Pedro de Portugal (1429–66), son of the prince

of that name already referred to, was led by the accidents of his own storm-tossed life—he lived for seven years in exile in Castile and died as king of Aragon—to initiate the fashion of writing in Castilian. As one of the first likewise to adopt the new Spanish trend away from the Provençal manner in favour of allegory and the cult of classical antiquity derived from Italy, his influence on his compatriots was doubly important. His own poems were inspired by deep feeling and much reflection on life. It was to him that the Marquês de Santillana (*q.v.*) addressed, *c.* 1449, his historic letter dealing with the origins of Peninsular verse. The constable was one of almost 200 poets represented in the *Cancioneiro Geral* (1516) of Garcia de Resende, covering the preceding three-quarters of a century. The main subjects of these 1,000-odd poems, in Portuguese and Castilian, are love, satire, and epigram. Discovery and conquest in the East hardly find an echo, even in the verse of those who had taken part in them. Instead theme and tone are predominantly trivial and treatment artificial; the compositions that reveal genuine feeling or serious intent are very few. Resende was himself a better poet than most of his contributors, notably in his stanzas on the death of Inês de Castro. Some names were destined notwithstanding to count among the foremost in Portuguese literature: Bernardim Ribeiro, Cristóvão Falcão, Gil Vicente, Francisco de Sá de Miranda (*qq.v.*). These typify the transition from the 15th-century Spanish school to the Italianate school of the 16th century. Ribeiro and Falcão, introducers of the bucolic style, poured new life into old forms and by their eclogues and *redondilhas* gave models which later writers worked by but rarely equaled.

Gil Vicente and Early Drama.—The emergence of the drama from its medieval swaddling clothes to the threshold of the modern play may be traced in the works of Gil Vicente (*q.v.*), court dramatist and greatest name in the Portuguese theatre, who, having no forerunners in Portugal, drew for his first pastoral-religious plays on Spain, chiefly on Juan del Encina (*q.v.*). Eleven of his 44 plays were written wholly, and another 17 partly, in Spanish. The trilogy of the *Barcas* (1517–19) reveals his dramatic power in serious vein, but even here can be seen his fondness for comic relief, by way of which he arrived at pure comedy and the study of character. In this lay his strength, in construction his weakness; and the latter consideration, not remedied by his successors, had its bearing on the phenomenon of a potential national theatre that may be said to have died with its founder. His real influence was felt in Spain. In centres where Vicente's plays were known and acted, writers for the stage did spring up, in number sufficient to allow afterward the term *Escola Velha*, or old school, of Gil Vicente, but none had the talent to compare with his achievement. The best known were Afonso Álvares in the religious vein, António Ribeiro Chiado, an unfrocked friar who wrote farces with a strong satirical bent, and his brother Jerónimo Ribeiro, likewise a satirist. António Prestes evinced in his plays more knowledge of folklore than dramatic competence. Baltasar Dias, a blind poet from Madeira, wrote simple religious plays which for long retained their popularity. One of the last of the school was Simão Machado, whose *Comédia de Dio* and *Comédia da pastora Alfeia* possessed something of Vicente's lyrical facility and skill in portraying peasant scenes.

By the time of Vicente's death, *c.* 1536, court favour had been withdrawn from the stage. The Inquisition, introduced into Portugal in that year, early declared war on the popular theatre on the charge of grossness, to counter which the Jesuits encouraged the writing of Latin tragicomedies or dramatized allegories for performance at religious or scholastic festivals. Vicente's own plays, which figure on the Spanish Index of 1559, were reduced in number to 35 and sadly mutilated in the second edition of 1586, and no new edition appeared for another 250 years. (See also **DRAMA: Modern Drama.**)

The Renaissance.—The movement commonly called the Renaissance reached Portugal both indirectly through Spain and directly from Italy, with which country there had been close cultural relations through the 15th century. Afonso V had Matthew of Pisa as tutor and summoned Justus Balduinus to his court to write the nation's history in Latin, while John II corresponded with

Politian. In the following century many famous humanists took up their abode in Portugal. Nicolas Cleynaerts taught Prince Henry, later cardinal and king, and lectured on the classics at Braga and Évora; Vassaeus directed a school of Latin at Braga; and George Buchanan accompanied other foreign professors to Coimbra when in 1547 John III reformed the university. Many distinguished Portuguese teachers returned from abroad to assist the king in his task, among them Aires Barbosa from Salamanca, André de Gouvêa of the Parisian college of St. Barbe, whom Montaigne called "*sans comparaison le plus grand principal de France*," Aquiles Estaço, and Diogo de Teive.

At home Portugal produced its scholars of note, André de Resende (*q.v.*), author of *De antiquitatibus Lusitaniae*, Francisco de Holanda, painter, architect, and author of *Quatro Diálogos da pintura antiga*, and many another. Women took a share in the intellectual movement of the time. The sisters Luisa and Angela Sigêa, Joana Vaz, and Paula Vicente, daughter of the dramatist, constituted an informal female academy under the presidency of the Infanta Maria, daughter of King Manuel. Luisa Sigêa (*c.* 1518–60) was both orientalist and poetess in Latin; Lianor de Noronha, of noble family, served letters by her encouragement of translations.

The Italianate School.—The return in 1526 of Francisco de Sá de Miranda (*q.v.*) after a six years' stay in Italy initiated a literary reform of far-reaching effect, though his *Obras* only appeared posthumously in 1595. Like his contemporary Garcilaso in Spain, he introduced and acclimatized the new poetic forms of sonnet, *canzone*, ode, and epistle in hendecasyllabic ottava rima and in tercets. At the same time he gave fresh vigour to the national octosyllable or *medida velha*, through his *Cartas* and *Sátiras* which, with the *Éclogas*, some in Portuguese, others in Castilian, are perhaps his most successful compositions. His chief disciple, António Ferreira (*q.v.*), a convinced classicist, wrote sonnets superior in form and style, along with odes and epistles too obviously reminiscent of Horace. Pero de Andrade Caminha, Diogo Bernardes, Frei Agostinho da Cruz, and André Falcão de Resende continued the erudite school which, after some opposition, definitely triumphed with Luis Vaz de Camões (*q.v.*). The *Lima* (1596) of Bernardes contains beautiful eclogues, while the religious poems of his brother Frei Agostinho are full of charm. Camões, for all his eminence in the epic, was greater still as a lyric poet: were the *Cem melhores poesias líricas da língua portuguesa* true to its title, wrote the compiler, D. Carolina Michaëlis de Vasconcelos, it would contain no other name. Here a profound classical education combined with perfect mastery of his instrument and a lifetime of checkered experience on which the poet had reflected deeply to produce in sonnets, eclogues, odes, elegies, and *canções* the greatest poetry in the language. *Os Lusíadas* ("The Portuguese"), his epic narrative of Portuguese achievement in the East, with which was interwoven the whole story of the nation and much else, took rank on its appearance in 1572 as the national poem par excellence and the greatest of all Renaissance epics after the Virgilian pattern. Of the many who were moved to emulation by its success none approached Camões in inspiration or poetic gifts. The least unsuccessful was perhaps Jerónimo Corte-Real (*q.v.*) with his long prosaic accounts of the *Segundo Cêrco de Dio* (1574) and the *Naufrágio de Sousa de Sepúlveda* (1594). Most of these poems, like the *Elegiada* (1588) of Luis Pereira Brandão on the disaster of Alcácer-Kebir, the *Primeiro Cêrco de Dio* (1589) of the chronicler Francisco de Andrade, and

Portuguese"), his epic narrative of Portuguese achievement in the East, with which was interwoven the whole story of the nation and much else, took rank on its appearance in 1572 as the national poem par excellence and the greatest of all Renaissance epics after the Virgilian pattern. Of the many who were moved to emulation by its success none approached Camões in inspiration or poetic gifts. The least unsuccessful was perhaps Jerónimo Corte-Real (*q.v.*) with his long prosaic accounts of the *Segundo Cêrco de Dio* (1574) and the *Naufrágio de Sousa de Sepúlveda* (1594). Most of these poems, like the *Elegiada* (1588) of Luis Pereira Brandão on the disaster of Alcácer-Kebir, the *Primeiro Cêrco de Dio* (1589) of the chronicler Francisco de Andrade, and

even the *Afonso Africano* (1611) of Vasco Mousinho de Quevedo, for all their futile allegory, contain vigorous descriptive passages.

In the drama Sá de Miranda and his followers protested against the name *auto*, restored that of comedy, and substituted prose for verse. Taking Terence commonly as their model, they produced not Portuguese characters but conventional Romano-Italian types. This revived classical comedy, artificial alike in subject and style, won the favour of humanists and the nobility, though its influence was to be short-lived. Plautus and Ariosto were present as well to Sá de Miranda when, avowedly to combat the school of Vicente, he wrote *Os Estrangeiros*, the first prose comedy, and *Os Vilhalpandos*, both actions being set in Italy. His *Cleopatra*, a first classical tragedy, is lost. António Ferreira (q.v.), a greater dramatist, likewise attempted both kinds: *O Cioso*, Italian even to the names of the personages, came nearer to being a comedy of character, but his fame rests chiefly on *Inês de Castro* (c. 1557), which treated the most moving tragic theme in the nation's history by reference not to Seneca but to Sophocles and Euripides. From Jorge Ferreira de Vasconcelos (c. 1515-85) came a "new invention" of another kind with *Eufrosina*: written under the influence of the Spanish novel *La Celestina* (c. 1499), which enjoyed a great vogue in Portugal, it was close kin to the Spanish school though essentially Portuguese in characters and general atmosphere. This and his other plays, *Ulissipo* and *Aulegrafia*, resemble novels in dialogue and contain a treasury of popular lore and wise and witty sayings introduced with a moral purpose.

16th-Century History.—Discovery and conquest in Africa, Asia, America, and on the ocean inspired historians as well as poets, and many achieved distinction in narrating these events. The best had themselves seen Portugal's new greatness in the building and were moved by patriotism to write of it, so that their records gain in vividness what they may lose in scientific detachment.

In the three "Decades" of his *Asia* (1552-63) João de Barros (q.v.), the Livy of his country, told in simple, vigorous language the deeds of his compatriots overseas down to 1526. His first "decade" undoubtedly influenced Camões, and together, one by his prose, the other by his verse, the two fixed the written language. This work, continued by the more critical and incisive Diogo do Couto (1542-1616), may claim to rank as the noblest historical monument of the century. The manuscript of Do Couto's *Décadas* 4-12, carrying the story to the end of the century, suffered shipwreck, fire, theft, and official delays, and reached publication piecemeal in partial and very unequal form. In his *Soldado prático* he added some acute observations on the causes of Portuguese decadence in the East. Ten years of investigation in India underlay the *História do descobrimento e conquista da Índia* (1552-54 and 1561) of Fernão Lopes de Castanheda (c. 1500-59), covering the first 40 years, a work which ranks close to those of Barros and Do Couto. António Galvão, a governor of the Moluccas who died at home a pauper, left a brief *Livro dos descobrimentos das Antilhas e Índia* (1563) full of curious observations cast in the form of annals. Gaspar Corrêa (c. 1495-c. 1565) likewise embodied intimate knowledge of the manners and customs of India in the picturesque prose of his *Lendas or Crônica dos feitos da Índia* (1551), a work remarkable for the vividness of its effects. Among other historical works dealing with the East were the *Comentários de Afonso d'Albuquerque* (1557), an account of the great captain and administrator by his son, and the *Tratado das cousas da China e de Ormuz* (1570) of the missionary Frei Gaspar da Cruz.

DAMIÃO DE GÓIS, PORTRAIT BY AL-
BRECHT DÜRER

From this spate of writing on expansion overseas attention returned, by way of chronicles of the monarchs who presided over it, to the history of Portugal itself. Damião de Góis (q.v.), diplomatist, traveler, humanist, and intimate friend of Erasmus, possessed an encyclopaedic mind and one of the most critical spirits of the age: his *Crónica* (1566-67) of Manuel the Fortunate, preceded by one of his son, later John III, is most valuable where the author's own feelings or experience come into play. Like Francisco de Andrade's uncritical *Crónica de D. João III* (1613), it still allowed Eastern affairs to

overshadow events at home; so too did Jerónimo Osório, "the Portuguese Cicero," whose *De rebus Emmanuelis regis Lusitaniae* (1571), based on Góis and written in Latin in order to make the story known *per omnes reipublicae Christianae regiones*, achieved considerable fame abroad. Frei Bernardo da Cruz, who was with his king at the disaster of Alcazarquivir, told the story of the reign in a *Crónica de D. Sebastião*; Miguel Lenteão de Andrade taken prisoner in the battle, related his experiences along with popular traditions and customs in his wide-ranging *Miscelânea*.

Works of travel likewise abounded and derive a particular importance from the fact that their authors were often the first Europeans to visit or at least to study the countries in question. Among the more noteworthy were the *Verdadeira informação das terras do Preste João* (1540) by Francisco Álvares, the *Itinerários* (1560 and 1565) of António Tenreiro and of Martim Afonso, the *Itinerário da Terra Santa* (1593) by Frei Pantaleão de Aveiro, the *Etiopia oriental* (1609) by Frei João dos Santos, and a much translated classic, the *História da vida do padre Francisco Xavier* (1600) by Padre João de Lucena. Important both as history and as human documents were the *Cartas* written home by Jesuits in China and Japan, of which collections were published in 1570 and 1598. An anonymous *Descobrimiento da Florida*, or Florida, and the *Tratado descritivo do Brasil em 1587* of Gabriel Soares de Sousa are reminders that Portugal was also present and active in the new world to the west. In all

this literature of travel the palm is still held for curious interest by the *Peregrinação* (1614) which Fernão Mendes Pinto (q.v.), prince of adventurers throughout the East, composed in his old age for his children's reading, and for tragic pathos by the *História trágico-marítima*, a collection first printed as such in 1735-36 of 12 contemporary narratives, told by survivors or based on their accounts, of the more notable disasters which befell Portuguese ships between 1552 and 1604, among them the stories of the "São João" wrecked on the Natal coast in 1552, which inspired Côrte-Real's epic poem as well as some poignant stanzas in the *Lustadas*, and of the "São Bento" which foundered when homeward bound in 1554 after carrying Camões to India.

The Novel and Other Prose.—Bernardim Ribeiro (q.v.), whose five eclogues introduced pastoral poetry to Portugal, was

equally an innovator in the pastoral novel with his *Saudades*, better known by its opening words *Menina e Moça* (published 1554-57). This tale of rustic love and melancholy, chivalresque elements mingling with the pastoral and lyric songs with the prose, transferred themes and emotions previously held the preserve of poetry to a new medium and explored them with scant concern for plot. From it Jorge de Montemôr (Montemayor; *q.v.*) drew some part of his inspiration for the *Diana* (c. 1559) which, written in Spanish, started a fashion subscribed to by Cervantes and Lope de Vega among many others and represents one of the outstanding contributions of Portugal to the neighbouring literature. Both countries shared in the new enthusiasm of the 16th century for the romance of chivalry, in an age when imperial enterprise to east and west was such as to blur the dividing line between fact and the most improbable flights of the imagination. The first work of João de Barros (*q.v.*), historian of empire, was in fact his *Crónica do Imperador Clarimundo* (1520), written purposely to develop his style for more serious tasks and serving, through the adventures of this fictitious progenitor of the kings of Portugal, his consistent aim of glorifying his native land. In the *Palmeirim de Inglaterra* (1544) Francisco de Moraes (*q.v.*) naturalized one branch of the Spanish descent of Amadís with an imaginative luxuriance and a purity of style which caused Cervantes to bracket it with the works of Homer. Its own Portuguese progeny, the *Dom Duardos* (1587) of Diogo Fernandes and Baltasar Gonçalves Lobato's *Dom Clarisol de Bretanha* (1602), were of an inferior order. The dramatist Ferreira de Vasconcelos kept alive memories of the Arthurian cycle with his *Sagrador* or *Memorial da segunda Távola Redonda* (1567). A very different type of fiction entered with the *Contos de proveito e exemplo* of Fernandes Trancoso, containing 38 tales derived from tradition or imitated from Boccaccio and others, which won and held favour for more than a century.

Among moralists three at least rank as masters of prose style: Frei Heitor Pinto for his *Imagem da Vida Cristã* (1563), Bishop Amador Arrais for his ten *Didlogos* (1589) on religious and other topics, and Frei Tomé de Jesus for his mystic and devotional treatise *Trabalhos de Jesus* (1602-09). The maxims of Joana da Gama entitled *Ditos da freira* (1555) form a curious if unsubtle psychological document. The roll of scientists includes the cosmographer and mathematician Pedro Nunes, inventor of the nonius, and the botanist Garcia da Orta, whose *Colíquios dos simples e drogas* (1563) was the first book to be printed in the East (Goa); while the form of Aristotelian scholastic philosophy professed at Coimbra had a succession of learned exponents, mainly in Latin, in which language also Francisco Sanches wrote his notable treatise *Quod nihil scitur* (1581).

The 17th Century.—From a literary as from a political point of view the new century found Portugal in a lamentable state of decadence. Long before the loss of independence to Spain in 1580 Spanish influence had brought about the introduction of the Inquisition, and with it censorship of books and the preparation of an Index; among its early victims was George Buchanan, at the instance of the Jesuits, into whose hands passed between 1552 and 1555 control of higher education. Cultism, inseparable at bottom from classical education, was already present—as in Camões and Ferreira de Vasconcelos—before Luis de Góngora y Argote (*q.v.*); but with the exhaustion of the national spirit that underlay political eclipse the influence of Góngora penetrated deeply. Its extent may be seen in the five volumes of the *Fénix renascida* (1716-28), which anthologizes the poetic production of the preceding century and reveals in the very titles of poems the emphatic futilities to which good talents could devote themselves. The trend, reinforced by the new fashion out of Italy of literary academies, survived the throwing-off of the Spanish yoke in 1640; Portuguese editions of Góngora appeared in 1646, 1647, and 1667. In 1649 there was founded the Academia dos Generosos, numbering many illustrious by rank and learning, and in 1663 the Academia dos Singulares.

In the bucolic vein a worthy disciple of Bernardim Ribeiro arose in Francisco Rodrigues Lobo (*q.v.*), whose long pastoral romance *A Primavera* (3 parts, 1601-14) showed, with the same delicate perception of nature, a gentler melancholy still and even more sluggish action, interspersed with songs which, with his

Éclogas (1605), earned him the title of the Portuguese Theocritus. Livelier and more varied interest attaches to the same author's *Côrte na aldeia e noites de inverno* (1619), a late flowering of Castiglione's *Cortegiano*. The foremost literary figure of the age was the encyclopaedic Francisco Manuel de Melo (*see* MELO, FRANCISCO MANUEL DE), at once a classic of Spanish and—with his *Epanáforas de vária história portuguesa* and *Apólogos dialogais*—of Portuguese literature, who strove hard, more successfully in prose than in verse, to free himself from subservience to Spanish form and style. Most lyricists of the period remained steeped in Gongorism or, writing in Spanish, have no place here. It suffices to mention Soror Violante do Céu, an exalted mystic praised as "the tenth muse," or the poems of Frei António das Chagas, who is better represented by his *Cartas espirituais* (1684-87). Satirical verse had two cultivators of merit in Tomás de Noronha and António Serrão de Castro, author of *Os Ratos da Inquisição*, a facetious fruit of his imprisonment by the Holy Office; the adherents of Gongorism were pilloried by Diogo de Sousa Camacho. Epic poets continued active, but few of their productions were more than rhymed chronicles. Their works span the century, from the *Condestabre de Portugal* (1610) of a poet already mentioned, Rodrigues Lobo, to the *Viriato trágico* of Brás Garcia de Mascarenhas, published posthumously in 1699; those falling between include the *Ulissea* (1636) of Gabriel Pereira de Castro, the *Malaca conquistada* (1634) of Francisco de Sá de Meneses, and the *Uliisipo* (1640) of Sousa de Macedo.

History, Oratory, and Drama.—Frei Bernardo de Brito (1569-1617), beginning his ponderous *Monarquia lusitana* (1597-1609) with the Creation, reached only to the founding of the monarchy. His work is a mass of legends lacking in foundation or critical sense, but both here and in the *Crónica de Cister* (1602) he proved himself a great stylist. Of the four continuers of the former work, the last three were no better equipped; the first, Frei António Brandão, who covered the period from Afonso Henriques to John II, wrote as a man of high intelligence and a learned and conscientious historian; his parts three and four appeared in 1632, parts five to eight between 1650 and 1727. Other historical works deserving of mention are the *Discursos vários políticos* (1624) of Manuel Severim de Faria, the *Crónica da Companhia de Jesus* (1645-47) of Padre Baltasar Teles, and the *Portugal restaurado* (1679-98) of Luís de Meneses, Conde de Ericeira. Baltasar Teles also edited in 1660 an *História geral da Etiópia a alta ou Preste João* of his fellow-Jesuit, the missionary Manuel de Almeida; and, although travel literature compares ill with that of the preceding century, note should be made of the *Itinerário da Índia por terra* (1611) of Frei Gaspar de S. Bernardino and of the *Relação do novo caminho . . . da Índia para Portugal* (1665) of Padre Manuel Godinho. Frei Luís de Sousa, a typical monastic chronicler, won lasting fame as a stylist with his *Vida de Frei Bartolomeu dos Mártires* (1619) and the *História de S. Domingos* (1623). Another notable biography, one of the best-known works of the century, was Jacinto Freire de Andrade's *Vida de D. João de Castro* (1651). Manuel de Faria e Sousa, a voluminous writer on Portuguese history and commentator of Camões, wrote in Spanish, as did Melo in his classic account of the 1640 *Guerre de Catalogne*.

The Jesuit António Vieira (*q.v.*), missionary and diplomatist and regarded for his *Cartas* as one of the greatest of all writers in Portuguese, repeated his triumphs of Bahia and Lisbon in Rome, which proclaimed him the prince of Catholic orators. Dying, Vieira considered the language safe in the hands of Padre Manuel Bernardes (1644-1710), a humble priest and recluse whose sermons and oratorical works *Luz e Calor*, *Nova Floresta*, and *Exercícios espirituais* breathed a calm serenity and naturalness alien to Vieira and exerted a powerful influence in freeing the language from the now outworn conceits of the *culteranos*. Padre Ferreira de Almeida's translation of the Bible (*Novo Testamento*, 1681; *Velho Testamento*, 1748-53) has considerable linguistic importance.

The popular theatre lived on obscurely in the *comédias de cordel*, mostly anonymous and never printed. Such plays as have survived are mainly religious and show the common Gongoristic abuse of metaphor and conceit. All through the century dramatists who

aspired to be heard wrote, like Jacinto Cordeiro and João de Matos Fragoso, in Spanish, with an occasional exception such as Melo's witty *Auto do Fidalgo Aprendiz* (1646). The court after 1640 preferred Italian opera, French plays, and Spanish *zarzuelas* to dramatic performances in the vernacular, to the detriment alike of native drama and of acting.

The 18th Century.—The 18th century, in Portugal as in Spain, was to be predominantly prosaic, even in poetry. In the opening decades bad taste was still rampant, but gradually signs appeared of a literary revolution which developed eventually into the Romantic movement. Men of liberal ideas went abroad to France and England, and to their exhortation and example were largely due the reforms which by degrees invaded every branch of letters. Of such were Alexandre de Gusmão, Xavier de Oliveira, Ribeiro Sanches, Correia da Serra, Avelar Brotero, and Francisco Manuel do Nascimento (*q.v.*). Earlier, Luís António Verney had poured scorn on prevailing methods of education in his *Verdadeiro método de estudar* (1746). New literary societies, variously called academies or "*arcádias*," cooperated in the task of reform. In 1720 John V, an imitator of Louis XIV, established the Academia da História; in its *Memórias* (15 vol., 1721–36) may be seen the excellent work done by its members, who included Manuel Caetano de Sousa, author of a colossal *História genealógica da casa real portuguesa* (1735–49), Barbosa Machado, compiler of the invaluable *Biblioteca Lusitana* (1741–58), and Soares da Silva, chronicler of the reign of John I. The Academia Real das Ciências, founded in 1779 by the Duque de Lafões, showed particular interest in language and literature and initiated specialized research and the study of Portuguese literary history (*Memórias de literatura*, 8 vol., 1792–1812). In its ranks were found nearly all the scholars of note at the end of the century, such as the ecclesiastical historian Frei Manuel do Cenáculo, the scientist of many parts Ribeiro dos Santos, Caetano do Amaral, a patient investigator into the origins of Portugal, João Pedro Ribeiro, who has been called his country's first modern historian, and the critics Francisco Alexandre Lobo, bishop of Viseu, Cardinal Saraiva, and Frei Fortunato de S. Boaventura.

The Arcádias.—In 1756 António Dinis da Cruz e Silva (*q.v.*) established with others the Arcádia Ulissiponense (or Lusitana), its first aim being the uprooting of Gongorism and Spanish influence generally; an indifferent poet himself in odes, elegies, and sonnets, his mock-heroic *O Hissope*, inspired by Boileau's *Le Lutrin*, was a telling satirical document. Pedro António Correia Garção (*q.v.*), the most prominent Arcadian, was a devotee of Horace and technically accomplished rather than inspired. The bucolic verse of Domingos dos Reis Quita signified a return to the native tradition of two centuries earlier. Sincerity and suffering spoke in the justly more famous *Marília*, a volume of love lyrics in a pastoral setting, of Tomás António Gonzaga (*q.v.*). In 1790 a Nova Arcádia came into being, its two most distinguished members the rival poets Manuel Maria Barbosa du Bocage (*q.v.*), a would-be second Camões in his life and in his lyrics who overspent himself and lives by a few sonnets, and José Agostinho de Macedo (*q.v.*), in whom inspiration fell below a notable industry, chiefly in the epic. Curvo Semedo was the only other "New Arcadian" of merit. Outside the Arcádias stood the "Dissidents," who numbered at least two writers of distinction. Few Portuguese satirists have possessed such equipment for the office as Nicolau Tolentino de Almeida (1740–1811), who painted the customs and follies of his day with devastating accuracy and distributed attacks or begged favours in the same sparkling verse. Francisco Manuel do Nascimento addressed himself perseveringly, at home and through 40 years of

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

FRANCISCO DO NASCIMENTO. ENGRAVING FROM HIS OBRAS COMPLETAS

exile, to the purifying and enrichment of the language and to restoring the cult of the *quincentistas* (16th-century poets). A convert to romanticism shortly before his death, he prepared the way for its triumph in Portugal.

Early in the century authors sprung from the people attempted a revival of the drama at the Bairro Alto and Mouraria theatres in Lisbon, where numerous pieces of low comedy were staged. The *Óperas portuguesas* of António José da Silva (*q.v.*), produced between 1733 and 1741, owe their name to the interspersing of the prose dialogue with arias, minuets, and *modinhas* (popular, light songs); if unremarkable in plot, style, or language, they have a certain comic force of invention. Nicolau Luís was a fertile adapter from the Spanish and Italian, his best play, on the ever-appelling tragic theme of *D. Inês de Castro* (1772), being an imitation of Vélez de Guevara; lifeless characters and conventional passions notwithstanding, his comedies long held the stage. Meanwhile the Arcádia Lusitana sought to raise the tone of the stage, finding its ideals in the classics of antiquity or of the 16th century but immediate inspiration in the contemporary French theatre. Its efforts failed from lack of dramatic talent and of popular appeal. Correia Garção led the way with two satirical comedies in blank verse, *Teatro Novo* and *Assembleia ou partida*, but did not persevere. Manuel de Figueiredo, setting out to write pieces "morally and dramatically correct," produced 14 volumes of plays in prose and verse (1804–15) on national subjects; utterly lacking in life, they were never acted. The three Greek tragedies of the bucolic poet Reis Quita, *Astarto*, *Megara*, *Hermione*, proved likewise stillborn; to them he added yet another *Inês de Castro*, reduced to the three unities, and a pastoral drama *Licore*.

Romanticism and After.—The 19th century witnessed a general revival of letters; again the initial stimulus came from abroad, but this time it proved more congenial to the native temperament. The chief exponents of romanticism were in poetry and the drama João B. de Almeida Garrett (*q.v.*) and in prose Alexandre Herculano (*q.v.*), both formed in exile, the price of their political liberalism. Almeida Garrett read contemporary foreign literature in England and France and, imbued with patriotic fervour, introduced his fellow countrymen to the new movement through two epics, *Camões* (1825) and *Dona Branca* (1826). His poetry, subjective in the short lyric, historical in longer compositions, remained always sincere and natural. António Feliciano de Castilho (*q.v.*), a gentle Romantic who still looked back to the Arcádias and beyond, exercised much influence over a younger generation of poets: João de Lemos and the group associated with him in *O Trovador* (1848), Soares de Passos, and Tomás Ribeiro, who won fame with his ardently patriotic *Dom Jaime* (1862). Mendes Leal, outstanding in the heroic vein, Francisco Gomes de Amorim, and Raimundo António de Bulhão Pato belong more or less to the same school.

In 1865 romanticism received a frontal attack in a revolt against the primacy of Castilho led by Antero de Quental, a student of German philosophy and poetry, and Teófilo Braga (*qq.v.*), disciple of Auguste Comte and author already of an epic of humanity, *Visão dos tempos* (1864). Literature gained considerably therefrom, and especially poetry. Quental enshrined his metaphysical pessimism and agony of thought in finely wrought sonnets. *Odes modernas* (1865), *Sonetos* (1881), which place him near to Heinrich Heine and Giacomo Leopardi. The *Campo de flores* (1893) of João de Deus (*q.v.*) contains some of the finest short poems in the language, of a spontaneous simplicity. Abílio Manuel Guerra Junqueiro (*q.v.*), heir to Victor Hugo, was a would-be social revolutionary swayed by grandiose ideas and overprone to grandiloquence in sonorous stanzas that, lit by his powerful imagination and pantheistic tendencies, constitute his finest poetry. Akin to him on a lower level was Duarte Gomes Leal (*q.v.*), a militant anti-Christian in *Claridades do Sul* (1875) and antimaterialist in *O Anti-Cristo* (1886), whose declamatory excesses could likewise yield to a quiet sincerity on humble themes. Cândido Gonçalves Crespo (1846–83), in his slender harvest of delicately chiseled verse

Miniaturas and *Nocturnos*, stood out as the first of his country's Parnassians. By contrast Cesário Verde (1855-86) addressed himself in unaffected style to surprising the poetic essence of common realities; through the posthumous *Livro de Cesário Verde* he became one of the rediscoveries of a later generation. The *Só* (1892) of António Nobre (q.v.) was intensely Portuguese in themes, mood (an all-pervading *saudade*), and rhythms; he typifies, with the sincere but nebulous pantheist Teixeira de Pascoais (q.v.), a cult of *saudosismo* that was to inspire a whole school of northern poets, and his influence went deep. French Symbolism found an enthusiastic adept in Eugénio de Castro (q.v.); in a long series of volumes from *Oaristos* (1890) to *Camaféus Romanos* (1921) and beyond he sought to fill his verse with imagery and colour while emptying it of all personal element, and was admitted for a period, after the death of Junqueiro, as the greatest of contemporary poets. Afonso Lopes Vieira (1878-1946) brought the rhythm of the sea as well as many traditional notes into his *Ilhas de bruma* (1918) and showed a rare artistry in his retellings of two earlier classics, *Amadís* and *Diana*.

Drama, the Novel, and History.—Almeida Garrett, seeking early to reinvigorate the drama, found that he had to create alike theatre, plays, actors, and audience. In *Um Auto de Gil Vicente*, *O Alageme de Santarém*, and especially in *Frei Luís de Sousa*, a tragedy of fatality and pathos, all written in prose as admirable as his poetry, he proved himself, after Vicente, his country's most notable dramatist. The historical bent was continued by José Mendes Leal (1818-86), Gomes de Amorim (1827-91), and Manuel Joaquim Pinheiro Chagas (1842-95), all three inclined to ultraromanticism. António Enes (1848-1901) dramatized questions of the day in a spirit of combative liberalism. Ernesto Biester (1829-80) wrote social drama, and Fernando Caldeira (1841-94), also no mean lyric poet, comedy. Good dialogue and sparkling wit marked the comedies of Gervásio Lobato (1850-95), some of the most popular of them written in collaboration with João da Câmara (1852-1908), who for his plays historical, social, and fanciful—*Afonso VI*, *A Rosa enfeitada*, *Os Velhos*—was accounted the outstanding dramatist of his day. Other historical playwrights include Henrique Lopes de Mendonça, Marcelino Mesquita, and the admirably gifted Júlio Dantas (1876-1962), remarkable for the wit, lightness of touch, and sense of atmosphere with which he reconstructed the past (*A Severa*, *Santa Inquisição*, *A Ceia dos Cardeais*, *Rosas de todo o ano*). With these plays of the early 20th century may be mentioned António Patrício's *Dinis e Isabel* (1919) and *D. João e a Máscara* (1924), the *Egas Moniz* (1918) of Jaime Cortesão, and *O Gebo e a Sombra* (1923), a tragedy of unrelieved gloom and considerable power by Raul Brandão.

Herculano, returning from exile with an enthusiasm for the Waverley Novels, launched the historical romance with *O Monasticon* (1844-48) and *Lendas e Narrativas* (1851). Many took up the kind, Oliveira Marreca, Arnaldo da Gama, Pinheiro Chagas, the most popular successes being *A última corrida de touros em Salvaterra* and *A Mocidade de D. João V* by Rebelo da Silva, and João de Andrade Corvo's *Um ano na corte*. This was the great age of the novel: Camilo Castelo Branco (q.v.), J. G. Gomes Coelho (better known as Júlio Dinis; q.v.), José Maria Eça de Queirós (q.v.) are names which would stand high in any country. The first, a great Impressionist, described to perfection the domestic and social scene (*Amor de Perdição*, *Amor de Salvação*, the various *Novelas do Minho*). Gomes Coelho depicted country life and scenery with much charm, as in *As Pupilas do Senhor Reitor*; *Uma Família Inglesa* describes English society in Oporto with a detail suggestive of Charles Dickens. Eça de Queirós introduced Naturalism with his powerful novel *O Crime do Padre Amaro*, followed by *O Primo Basílio* and *Os Maias*; he was the greatest of the realists, though his materialism was always tempered by a sensitive imagination, and his last novels, *A Ilustre Casa de Ramires* and *A Cidade e as Serras*, place him rather with the regionalists. Naturalism claimed too Lourenço Pinto, Luís de Magalhães, and the much greater Francisco Teixeira de Queirós (1849-1919), who sought to lay bare contemporary society in the 15 volumes of his two series *Comédia do campo* and *Comédia burguesa*. Antero de Figueiredo, a stylist who excelled in regionalist sketches (*Jornadas*

em Portugal, *Senhora do Amparo*), showed historical imagination of a high order in his fictionalized biographies *D. Pedro e D. Inês* (1913), *Leonor Teles* (1916), *D. Sebastião* (1925). Raul Brandão in *Os Pobres* (1906) and *Os Pescadores* (1923) brought a poignant realism to the description of the sufferings of humble folk.

With his magnum opus the *História de Portugal* (1846-53), on a scale which allowed it to reach only to 1279, and the *História da Inquisição em Portugal* (1854-59) Herculano established himself as the leader of modern Peninsular historians; in 1856 he initiated the important series *Portugaliae Monumenta Historica*. Historiography flourished with names such as the Visconde de Santarém, historian of the cortes, José Simão da Luz Soriano of constitutionalism, L. A. Rebelo da Silva of the period of Spanish rule under the Philips, and José Maria Latino Coelho of the dictatorship of Pombal; if all four have been overtaken by later research, the two latter still rank highly as stylists. Henrique da Gama Barros (1833-1925) and António da Costa Lobo (1840-1913) followed in the footsteps of Herculano, the first with his erudite *História da administração pública em Portugal nos séculos xii a xv*, the second with the unfinished *História da sociedade em Portugal no século xv*, both monuments of scientific objectivity. The works of J. P. de Oliveira Martins (q.v.), if not similarly grounded in original research, gave proof of psychological imagination, a notable capacity for general ideas, and the gift of picturesque narration; at once the most artistic and most philosophically minded historian of his generation, he left in his numerous writings a vast portrait gallery of the great figures of his country (*História da civilização ibérica*, *História de Portugal*, *Portugal contemporâneo*, *Os Filhos de D. João I*, *A Vida de Nuno Álvares*). The 20th century has seen accentuated the trend toward scientific documentation and objectivity. Fortunato de Almeida followed up an *História da Igreja em Portugal* with a masterly *História de Portugal* (6 vol., 1922-27). The monumental *História de Portugal* edited by Damião Peres and others (8 vol., 1928-38) provides an exhaustive treatment of the whole field.

The 20th Century.—The passage from monarchy to republic in 1910 was accompanied by a revisionary urge in literature associated chiefly with Oporto and self-styled the *Renascença portuguesa*. Leonardo Coimbra (1883-1936) was its philosopher, António Sérgio de Sousa (1883-) its critic and historian. Its poets—Mário Beirão (*O último Lusitano*, 1913), Augusto Casimiro (*A Vitória do Homem*, 1910; *A Evocação da Vida*, 1912), and João de Barros (*Oração à Pátria*, 1917)—adopted the *saudosismo* of Teixeira de Pascoais (see above) as key to the nation's soul and so to the recovery of greatness, though the inadequacy of mere nostalgic regret for the past as a principle of action was soon realized. Against this the "Integralist" school reacted from 1913 onward in favour of Catholic monarchist tradition, under the leadership of the historian and poet António Sardinha (1888-1925); among his followers were the Conde de Monsaraz and Hipólito Raposo. The formula of Afonso Lopes Vieira, another sensitive traditionalist, *reaportuguesar Portugal tornando-o europeu* (an almost untranslatable phrase expressing the intention to make Portugal really Portugal again by making it once more truly European), synthesized in some degree the objectives of both schools, and received impetus from Portugal's intervention in World War I. Less was heard thereafter of the cult of the past, and poetry, while responsive to developments abroad, grew personal and introspective in a vein that proclaimed its affinity with that of Cesário Verde and António Nobre. Fernando Pessoa published in his lifetime only *Mensagem* (1934); posthumously he stood revealed as a complex personality responsive to all winds that blew, and gained acceptance as the most inspired poet of his generation. His influence enriched poetry's moods and resources without imposing a poetic school. Prominent among later poets were José Régio (1901-) and Miguel Torga (1907-). Régio, poet, novelist, and dramatist, established himself in a dozen volumes, from *Poemas de Deus e do Diabo* (1925) to *El-Rei Sebastião* (1949), as a religious, if sorely perplexed, poet of power, and the most outstanding dramatist of his time. Torga's works, from the verse in *Ansiedade* (1928) to the eighth volume of his *Diário* (1960), reveal a less introspective mind, with a robust faith in the primitive virtues of mankind.

Among novelists, Aquilino Ribeiro (1885–1963) was a vigorous personality and prolific writer with wide-ranging lexical and stylistic resources, and themes often centring on his native province of Beira. In Ribeiro the delight of life in all its aspects—gay, carnal, harsh—stands close to awareness of inevitable decay and death (*Jardim das Tormentas*, 1913; *A Via Sinuosa*, 1916; *Caminhos Errados*, 1947; *A Casa Grande de Romarigães*, 1957). J. M. Ferreira de Castro (1898–), author of *A Selva* (1930; *Jungle*, 1934), a brilliant evocation of his early years as a worker in an Amazonian rubber plantation; and of *Terra Fria* (1934) and *A Lã e a Neve* (1947), is deeply concerned with social problems. The widely traveled J. Paço de Arcos (1908–) is a readable and penetrating observer, particularly of the upper levels of Lisbon society from the end of World War I onward (*Ana Paula*, 1938; *Ansiedade*, 1940; *Tons Verdes em Fundo Escuro*, 1946). J. Rodrigues Miguéis (1901–) united social and psychological trends in *Páscoa Feliz* (1932) and *Onde a Noite se acaba* (1946). Novelists who treat African colonial questions include Castro Soromenho (1910– ; *Terra Morta*, 1950). An important woman novelist of the postwar period is Agustina Bessa Luís (1922–), whose *A Sibila* (1955) is a complex psychological study.

Notable work has also been done in history (Damião Peres, J. M. Queirós Veloso, Luís Gonzaga de Azevedo, David Lopes) and in literary criticism (F. de Figueiredo, Manuel Rodrigues Lapa, Hernâni Cidade, A. J. Saraiva, J. Gaspar Simões). Through their work, Portugal's long and distinguished record in action and letters has at last become more adequately known.

For the literature of Brazil in Portuguese, see IBERO-AMERICAN LITERATURE; see also references under "Portuguese Literature" in the Index.

PORTUGUESE MAN-OF-WAR, any of the large floating hydrozoan coelenterates of the genus *Physalia*, belonging to the group Siphonophora. *Physalia* has a large gas-filled float that may be as long as 10 or 12 in. and is commonly seen in tropical or subtropical waters of all oceans. These animals are sometimes blown ashore in large numbers, and their bright blue, red and some-

FIG. 1.—YOUNG SPECIMEN OF PHYSALIA

times greenish coloured floats can hardly be overlooked. Beneath the float there hang numerous polyps of a highly polymorphic nature; they may be described as protective, nutritive and reproductive (see POLYP).

The protective polyps (dactylozooids) are of two sorts, large ones with very long tentacles and more numerous small ones with small tentacles. The large dactylozooids possess tentacles specialized as fishing or food-catching tentacles that may be from several feet to several yards long. It is these fishing tentacles, heavily armed with nematocysts, that enable the Portuguese man-of-war to capture animals, including fish, up to its own size. The nematocysts of *Physalia* are larger than those of most coelenterates and contain potent toxins; the sting is extremely painful and, in the extreme, can cause death in man.

The feeding or nutritive polyps (gastrozooids) occur in clusters, and the individual zooids do not have tentacles. Once food has been captured by the fishing tentacles, those tentacles contract and carry the food up beneath the float where the gastrozooids can reach it. The gastrozooids apply their mouths to the surface of a food item and will swallow the item if it is small. If it is a large food organism, such as a fish, the mouths of many gastrozooids will spread out over the surface of the captured animal, sometimes completely covering the whole organism. Digestion is believed to be similar to that in other coelenterates.

The remaining zooids, the reproductive ones, are more complex than the others. They are complexly branched structures, perhaps representing many individual zooids. These structures, called gonodendra, are made up of clusters of male reproductive units (male gonophores), clusters of female reproductive units (the medusoid female gonophores), long gelatinous processes called gelatinous zooids and short finger-like processes called gonopals. Sometimes, but apparently not always, the medusoid female gonophores may be released at sexual maturity. The early stages in the development of *Physalia* are not known, but once the first polyp appears, part of it becomes

FIG. 2.—CLUSTER OF POLYPS FROM SEXUALLY MATURE PHYSALIA

the float while an intermediate position, presumably homologous to the stem of most siphonophores, differentiates as a budding region from which the rest of the colony develops.

The zooids are set at an angle beneath the float and act like the keel of a ship; thus, instead of simply blowing about the ocean's surface with the wind, these animals tack at an angle to the wind. The relationship of the float to the zooids is different in Northern and Southern Hemisphere representatives of this animal, such that those in the north tack to the left of the wind and those in the south to the right of the wind. The same phenomenon is also known for the colonial hydroid *Velella* (the by-the-wind sailor), whose sail is differently set in the two hemispheres.

The float of *Physalia* has a pore through which the contained gas may escape, allowing the animal to sink. In a short while, the gas-secreting tissues of the float will refill it and the animal will again return to the surface.

The Portuguese man-of-war commonly is accompanied by a fish, *Nomeus*, which lives among the tentacles of the hydroid and is said to share the food *Physalia* catches. *Nomeus* has also been reported to eat the tentacles of *Physalia*. As long as *Nomeus* is healthy and has no wounds it is not harmed by *Physalia*, and the presence of the fish does not cause discharge of the nematocysts. However, once wounded, *Nomeus* too falls prey to its host just as does any other fish. The nature and origin of the immunity of this fish to the potent nematocysts of *Physalia* is not understood. See HYDROZOA.

PORTUGUESE TIMOR (COLONIA DE TIMOR): see TIMOR.

PORTUGUESE WEST AFRICA: see ANGOLA.

PORTULACACEAE, the purslane family of plants, containing 16 or more genera and more than 500 species of widely distributed rather fleshy annual or perennial herbs or subshrubs. The family is characterized by simple, often cylindrical leaves and flowers with usually two green herbaceous sepals and from four to six petals (sometimes fewer).

A few members are grown for ornament, among them rose moss (*Portulaca grandiflora*), spring beauty (*Claytonia*), and fume-flower (*Talinum*). A very troublesome weed in many sections of the United States is the garden purslane or pusley (see PURSLANE).

PORTUNUS (PORTUMNUS), in Roman cult originally a god either of gates and doors (from *porta*) or harbours (from *portus*), eventually associated with both. In the former capacity he was probably connected with Janus (*q.v.*), but the degree of their association is conjectural. At Rome he had his own priest, the *flamen Portunalis*, and a festival, the Portunalia, celebrated on Aug. 17 in his temple near the *pons Aemilius*. He was similarly worshipped at Ostia. The conjecture that he is the god of the gates and keys of granaries may explain the location of his shrine near the storehouses of the Tiber and his festival in the harvest season. He was, however, definitely connected with the guiding of ships to harbour (Virgil, *Aeneid*, v, 241; cf. Cicero, *Nat. deor.*, ii, xxvi), and he came to be associated with the Greek marine deity Palaemon-Melicertes. He is represented as a youth bearing keys.

BIBLIOGRAPHY.—W. W. Fowler, *Roman Festivals*, pp. 202-204 (1899); H. Papehoff in Pauly-Wissowa, *Real-Encyclopädie der klassischen Altertumswissenschaft*, s.v.; Platner-Ashby, *Topographical Dictionary*, s.v. *Portunium*. (R. B. LD.)

PORTUS (now about a mile inland) was the harbour town of Rome in the late empire, 2½ mi. (4 km.) N of Ostia (*q.v.*) at the mouth of the Tiber. The republican river harbour had proved increasingly inadequate because of the sandbar at the mouth and the narrowness of the river; the emperor Claudius therefore built an artificial harbour to the north and connected it by canal with the Tiber and so with Rome. Two long moles were built out to sea enclosing about 160 ac. (65 ha.); and a giant merchantman, filled with concrete, was sunk to provide the foundation for a great lighthouse. The work, begun A.D. 42, was completed in

Nero's reign, but in 62 a bad storm wrecked 200 ships in the harbour. Trajan added an inner hexagonal basin (97 ac.), connected by canal with the Claudian harbour and with the Tiber. The double harbour was able to handle a considerably increased tonnage in greater security.

Very little is known of the building associated with the Claudian harbour, but most of the plan of Trajan's harbour can be restored. Part of the area between the two harbours was reserved for an official residence; the rest of the basin was surrounded by large standardized warehouses for corn, oil, and other commodities. At first the harbour was controlled from Ostia; most of the workers lived in the old town, and some of the smaller ships continued to use the river harbour. But when trade declined the emphasis shifted. Constantine recognized realities when he made Portus an independent community in the early 4th century. Residential quarters had developed to the east and south of the harbour. Among the cults already attested are those of Liber Pater, Bona Dea, Cybele, Sarapis, Isis, Mithras, and Marnas; by the end of Constantine's reign at the latest there was a Christian bishop. The main cemeteries were developed outside the eastern gate along the Via Portuensis which led to Rome and, on the south side of the canal, along the road which led to Ostia. A substantial sector of the latter cemetery has been excavated, revealing an interesting and well-built series of mainly 2nd-century tombs of harbour workers. Portus was sacked by Alaric (408), but quickly recovered. It was still inhabited, with at least seven churches, in the 11th century, but by the 9th century the harbour and canal were silted up and out of use. The river harbour again became Rome's port until Trajan's canal was cleared and reopened in 1618.

The site was bought by the Torlonia family in 1856, and private excavations have unearthed parts of buildings, inscriptions, and sculpture, most of which can be seen in the Torlonia Museum in Rome. The building of a new airport at Fiumicino has revealed more clearly the main outlines of the Claudian harbour.

PORUS (4th century B.C.), an Indian prince, ruler of the country between the Hydaspes (Jhelum) and Acesines (Chenab) rivers at the time of Alexander the Great's invasion (327-326 B.C.). In the battle of the Hydaspes (*q.v.*) he offered a desperate resistance and Alexander, struck by his independent spirit, allowed him to retain his kingdom, which he increased by the addition of territory. Thenceforth a loyal supporter of Alexander, Porus held the position of Macedonian satrap when he was assassinated some time between 321 and 315 B.C.

The name Porus, which is not known in Indian sources, has been conjecturally interpreted as standing for Paurava; *i.e.*, the ruler of the Purus, a tribe known in this region from Vedic times.

See Arrian, v, 8, 4 ff.; Plutarch, *Alexander*, 60 ff. (J. BR.)

PORVOO (Swedish *Borçå*), a seaport in Uusimaa lääni (county), Fin., lies about 35 mi. (56 km.) NE of Helsinki by road, to which it is also linked by rail. The population (11,875 in 1960) is predominantly Swedish-speaking. Porvoo possesses a beautiful Gothic cathedral built in 1414-18, the old school building (1760) which now serves as the chapter house, and the home of the national poet Johan Ludvig Runeberg. Since 1723 Porvoo has been the seat of a bishopric. There are several educational institutions and industrial enterprises. Porvoo was granted town rights in 1346. It was there in 1809 that the Russian tsar Alexander I, having summoned a special Finnish diet, granted Finland a constitution as a semiautonomous grand duchy with the tsar as grand duke. (E.-S. KÜ.)

POSADA, JOSÉ GUADALUPE (1852-1913), Mexican print maker, was born on Feb. 2, 1852, in Aguascalientes. As a child he worked as a farm labourer and in a pottery factory. He taught school for a short time and then began to draw, inspired largely by posters for the Rea circus. Gradually he was attracted to print making and became a kind of pictorial journalist with the publication of thousands of broadside illustrations and popular

book and song covers. He may be regarded as one of the greatest popular artists of all time. Contrary to belief, most of his works were not executed in woodcut, but engraved or etched in relief on type metal. Posada died Jan. 20, 1913, in Mexico City.

See Carl O. Schniewind and Hugh L. Edwards, *Posada: Printmaker to the Mexican People* (1944). (H. Es.)

POSEIDON, in Greek mythology, god of the sea and of water generally. Originally he was probably a supreme deity, who was later fitted into a more specialized place in the Hellenic pantheon. Philologists interpret his name as meaning either "husband of Earth" or "lord of the earth." Homer tells the myth that he was a son of Cronus (*q.v.*) and Rhea and brother of Zeus and Hades. When the three brothers deposed their father, the kingdom of the sea fell by lot to Poseidon, whom Homer represents as dwelling in a palace in the depths of the Aegean. His weapon was the trident which he used to raise storms and also to split rocks, but it seems originally to have been a long-handled fish spear.

Beside these marine aspects, Poseidon was the god of earthquakes, his oldest titles being *gaieochos* ("holder of the earth") and *enosichthon* ("land-shaker") or *enosigaios* ("earth-shaker"). His oldest places of worship in Greece itself were many of them inland: in Thessaly, in Boeotia, and particularly in Arcadia, where he was associated as mate with Demeter (*q.v.*). Also in these places and elsewhere he was closely associated with horses. His union with Demeter was said to have been in this shape, their offspring being the horse Arion, and he was by Medusa the father of Pegasus, the winged horse. Modern scholars have rejected the idea that Poseidon's connection with horses was derived from association with rushing streams or the white crests of waves; in-

stead they usually agree that he came to Greece as the god of the earliest Hellenes who also introduced the first horses to the country. This theory fits well with Poseidon's prominence as god of the Ionians, who must have taken him with them when they colonized Asia Minor after the Dorian invasion. There they held a joint festival, the Panionia, at which bulls were sacrificed to Poseidon. The association of bulls with the god suggests a link with Minoan Crete. At Ephesus the attendants at his worship were called *tauroi* ("bulls").

In Athens the myth told how Poseidon and Athena contested the sovereignty of Attica. The decision of the citizens was to be determined by the gifts bestowed by the divinities. Poseidon with a blow of his trident created a salt spring on the Acropolis (or, according to another version, caused a war-horse to spring from the ground), but Athena triumphantly produced beside it the first olive tree, which the citizens declared to be the more acceptable gift. However, Poseidon received worship in Attica, particularly at Colonus as *hippios* ("of horses"). Elsewhere he was associated with freshwater springs, as for instance in the Argolid at Amymone, named after a nymph whom he had loved. The importance of water in fertility may partly explain the connection with Demeter.

Poseidon was not as prominent as Zeus in Greek mythology. He was the father of Pelias and Neleus by Tyro, the daughter of Salmones, and thus became the divine ancestor of the royal families of Thessaly and Messenia. But otherwise his offspring were mostly giants and savage creatures such as Orion, Antaeus, and Polyphemus, which expressed the general view of his character as violent. In the *Iliad* Poseidon is on the side of the Greeks because of his hostility to King Laomedon (*q.v.*), who defrauded him of his reward for building the walls of Troy. In the *Odyssey* his persistent hostility to Odysseus is explained by the latter's blinding of his son Polyphemus. According to Hesiod, Poseidon was married to Amphitrite, one of the Nereids.

The chief festival in Poseidon's honour was the Isthmia, celebrated in alternate years near the Isthmus of Corinth and the scene of famous athletic contests (see *GAMES, CLASSICAL*). But his character as a sea-god, which tended to develop at the expense of other aspects, became the most prominent in art, where he is shown with the attributes of the trident, the dolphin, and the tunny fish. The contest with Athena was carved on the west pediment of the Parthenon (now in the British Museum, London). Sculptures of Poseidon usually represent him as resembling Zeus but less dignified and more tousled. The Romans, ignoring his other aspects, identified him as sea-god with Neptune (*q.v.*).

POSEIDONIUS (POSIDONIUS) (c. 135-c. 50 B.C.), nicknamed "the Athlete," Stoic philosopher, the most learned man of his time and perhaps of all the school. A native of Apamea in Syria and a pupil of Panaetius, he spent many years in travel and scientific researches in Spain (particularly at Gades), Africa, Italy, Gaul, Liguria and Sicily and on the eastern shores of the Adriatic. When he settled as a teacher at Rhodes his fame attracted numerous scholars; next to Panaetius he did most, by writings and personal intercourse, to spread Stoicism in the Roman world, and he became well known to many leading men, such as Marius, Rutilius Rufus, Pompey and Cicero. The last-named studied under him (78-77 B.C.) and speaks as his friend.

The titles and subjects of more than 20 of his works, now lost, are known. In common with other Stoics of the middle period, he displayed eclectic tendencies, following the older Stoics, Panaetius, Plato and Aristotle. Unquestionably more of a polymath than a philosopher, he appears uncritical and superficial. His inquiries, however, were criticized by Strabo as alien to the Stoic school. In natural science, geography, natural history, mathematics and astronomy he took a genuine interest. He sought to determine the distance and magnitude of the sun and to calculate the diameter of the earth and the influence of the moon on the tides. POSITIVISM, a philosophical term which, in its broader sense, may be applied to any system that confines itself to the data of experience and excludes a priori or metaphysical speculations. In this sense the term is commonly applied to the empirical philosophers, although in fact reservations ought to be made (John Locke and David Hume accept mathematics, Locke and George Berkeley accept a knowledge of the soul and of God, on nonempirical grounds). John Stuart Mill's "experience philosophy" is positivistic in this sense. Positivists have usually held that theological and metaphysical questions arise but cannot in fact be answered by any method available to men. Others, however, have dismissed such questions as meaningless. This second view connects with pragmatism and with logical positivism (*q.v.*) and also with the hints to be found in Berkeley and in Hume of an experience test of meaning. Positivism emphasizes the achievements of science; but questions arise even within the sciences which do not seem to be answerable by experimental methods. Ernst Mach attempted to assign an experience meaning to such theoretical questions and to relate theories directly to the evidence for them.

More narrowly, the term describes the philosophy of Auguste Comte (*q.v.*), who held that human thought had passed inevitably through a theological stage into a metaphysical stage and was passing into a positive or scientific stage. Comte held that the religious impulse would survive the decay of revealed religion and ought to have an object. He projected a worship of man, with churches, calendar and hierarchy. Disciples (F. Harrison, R. Congreve, *et al.*) founded such a church in England, but Mill, who inclined to accept the religion, repudiated Comte's organization.

See also references under "Positivism" in the Index.

See Thomas Whittaker, *Comte and Mill* (1908). (K. W. B.)

POSSE COMITATUS, an ancient English institution consisting of the shire's force of able-bodied private citizens summoned to assist in maintaining public order. This "power of the county," originally raised and commanded by the sheriff, became a purely civil instrument as the sheriff's office early lost its military functions. From time to time legislation gave authority to other peace officers and magistrates to call upon the power of the county.

While Blackstone stated that liability to serve extended to every person over the age of 15 and under the degree of peer, judicial interpretation (of a riot act of Henry IV) excluded also women, clergymen, and the infirm. Failure to respond to the call subjected one to fine and imprisonment. The English sheriff ceased in the 19th century to be a police officer, but an act of 1887 still required every person in the county to be ready and apparelled (*i.e.*, armed) at the sheriff's command to arrest a felon or to assist if there were resistance to the execution of a writ. In the U.S., the posse comitatus was perhaps most important on the frontier, but it has been preserved as an institution in many states through the middle of the 20th century. Statutes confer on sheriffs and other peace officers authority to summon the power of the county. Some have made it a crime to refuse assistance. In general, its members have been privileged to use force if necessary to achieve a posse's legitimate ends, but states' laws differ as to the legal liability of one who in good faith aids an officer himself acting beyond his authority. (V. No.)

POSSESSION, a state in which the behaviour of a person is interpreted as evidence that he is under the direct control of an external supernatural power. Symptoms of possession include violent, unusual movements, shrieking, groaning, and uttering disconnected or strange words (*see* TONGUES, GIFT OF). Occasionally a normally pious member of a religious body becomes incapable of prayer, utters blasphemies, or exhibits terror or hatred of sacred persons or objects. Christianity and some other religions allow for the possibility that some of these states have an evil transcendental cause (*see* EXORCISM). Most scientific studies treat them as psychophysical manifestations to be dealt with medically or in terms of social psychology. Conditions historically termed demonic possession (*see* DEMON) have come to be treated as epilepsy, hysteria, somnambulism, schizophrenia, or other forms of natural illness (*see* NEUROSES; PSYCHOSES).

In some forms of possession the person becomes ill and is regarded by his community as having committed some spiritual transgression; recovery is held to require expiation of his sin, often by sacrifice. In other types the possessed person is conceived as a medium for the spirit controlling him, functioning as an intermediary between spirits and men. His major role is usually to diagnose and heal spirit-afflicted patients (*see* SPIRITUALISM; SHAMANISM). In such case the trance behaviour of the medium is often self-induced (autohypnotic); it may be stimulated by drugs, drumming, or collective hysteria. In his trance the medium appears genuinely insensible to ordinary stimuli. Faking the possessed condition to perform the therapeutic role (and collect the fee) seems rare.

The phenomena of possession are known among civilized as well as primitive people, and instances have been reported from societies as far apart in space and time as those of ancient Greece, China, and Western Europe. Apart from its therapeutic function, possession may take the form of religious ecstasy and so offer mystical satisfactions and psychological release to those possessed. Thus possession cults flourish in modern times—the outstanding example being the Voodoo (*q.v.*) cults of Haiti—even in communities that adhere to Christianity or some other major religion. *See* also ANIMISM; DEVIL; PSYCHICAL RESEARCH; RELIGION; LYCANTHROPY.

Beattie, "The Ghost Cult in Bunyoro," *Ethnology*, vol. 3 (April 1964). (R. F.)

POSSESSION (IN LAW) signifies that a person has acquired, with the intention to own, either a very considerable degree of physical control over a physical thing, such as land or a chattel, or the legal right to control intangible property, such as a credit. With respect to land and chattels, possession may well have started as a physical fact, but possession today is often an abstraction. For instance, a servant or an employee may have custody of an object, but he does not have possession; his employer does, even though he may be thousands of miles from the object he owns. Furthermore, except in the most abstract way, it is not possible to speak of the "possession" of intangible property.

In the development of the Roman legal system, possession tended to assume more importance than proprietary rights, and the same is true of the Anglo-American system. Thus possession tends to be regarded as *prima facie* evidence of the right of ownership; it gives this right against everyone except the rightful owner. Mere possession by a finder is sufficient to provide good grounds for an action against one who deprives him of the object with no better right than his own.

See PERSONAL PROPERTY; REAL PROPERTY AND CONVEYANCING, LAWS OF. (A. D.M.)

POST, EMILY PRICE (1872–1960), U.S. writer whose name was to become synonymous with proper behaviour and the rules of etiquette, was born in Baltimore, Md., on Oct. 27, 1872, and as a young girl moved with her family to New York City,

where her father, Bruce Price, achieved eminence as an architect. She was privately educated and in 1892 was married to Edwin M. Post. When circumstances impelled her to earn an income, she turned to the writing of magazine articles and light fiction, beginning with a novel, *The Flight of a Moth* (1904). *Etiquette* (1922), which she undertook at the request of the publisher, was an immediate success and established her as the outstanding authority on the subject; at the time of her death, in New York City on Sept. 25, 1960, it was in its 10th edition and 90th printing. Quantities of letters requesting advice on specific situations led to her syndicated newspaper column, and for a number of years she also had her own successful radio program.

Mrs. Post's advice was informed by her humanity and common sense and by her conviction that the basis of the rules of etiquette was consideration for others. "No one should do anything that can either annoy or offend the sensibilities of others," she wrote. Earlier books on the subject assumed that affluence and elegance on the part of the reader; Mrs. Post directed her ideas to the ordinary person who was aware of the need for good manners. She strove to make gentleness and courtesy attractive to everyone.

See E. M. Post, Jr., *Truly Emily Post* (1961), a biography by her son. (E. M. P.)

POST, PIETER (1608–1669), Dutch architect and painter, one of the principal architects of the Dutch golden age, was born at Haarlem and died at The Hague. He was a contemporary of Rembrandt and secretary to Constantijn Huygens. Though Post began his career as a painter, he had by 1633, in collaboration with Jacob van Campen, designed the exquisite Mauritshuis at The Hague, thus showing his mastery of the typical Dutch Baroque style. In 1645 he became architect to the stadtholder Frederick Henry. With Campen he designed the House in the Wood (Huis ten Bosch) at The Hague (1645–47) and, independently, Swanenburg House (1645), Nieuwkoop almshouses at The Hague (1658), and the weighhouse in Leiden (1658). Post's town hall at Maastricht (1656 ff.) is one of the outstanding buildings of the 17th century in the Netherlands. Post and Campen are notable for anticipating some of the architectural refinements of 18th-century France and for the influence they exerted on English architecture.

POST, WILEY (1898–1935), one of the most colourful figures of the early years of U.S. aviation, was born on Nov. 22, 1898, on a farm near Grand Saline, Tex., and grew up in the oil country of Texas and Oklahoma. Of natural mechanical bent, young Post worked first on well-drilling rigs, then became interested in gasoline-driven engines and in the airplane flights of the barnstormers who performed at county fairs. He began his career as a featured parachute jumper in tours throughout the U.S. Determined to purchase his own airplane, he returned to oil drilling to earn money. While working as a driller, he suffered an accident to his left eye, which was removed, but this did not prevent him from learning to fly. Backed by a wealthy Oklahoma oilman, F. C. Hall, for whom he became personal pilot, Post purchased the Lockheed monoplane "Winnie Mae" and proceeded to set an astonishing series of records, culminating in his solo round-the-world flight July 15–22, 1933. He covered a total of 15,596 mi. in 7 days, 18 hr., and 49 min. On this flight Post proved the value of navigation instruments, including the automatic pilot, that later came into common use in airline service. He had made an earlier round-the-world trip in the same airplane June 23–July 1, 1931. On that flight he had been accompanied by Harold Gatty as navigator.

Post also did pioneering work in high-altitude flying. Convinced of the feasibility of flying at increased speed in the rarefied air of the sub-stratosphere, he designed and tested a flying suit that would maintain low-altitude pressure while flying at great height. This suit was the prototype of those later used by military pilots.

In August 1935, while flying in Alaska accompanied by the hu-

morist Will Rogers, Post and his famous passenger were killed in a plane crash near Point Barrow.

See W. Post and H. Gatty, *Around the World in Eight Days* (1931). (S. P. J.)

POSTAL SERVICES (in British usage simply "posts"), the receipt and delivery of letters, postcards, and small packages by a government agency for a small fee paid for each item by the sender. In highly industrialized countries the post office makes use of a complex network of communications extending to all parts of the country, and to foreign lands, to provide fast, dependable, and inexpensive postal service. In such countries the post office achieves the status of a big business and makes an important contribution to the economic and cultural life of the nation. Because of the existence of post offices in every town and city, many governments have assigned to their post-office departments a variety of miscellaneous functions such as banking, selling licences and revenue stamps, selling government stock, and handling payments under specific welfare programs.

I. GREAT BRITAIN

A. GENERAL HISTORY

The history of postal services goes back to the early days of the great empires of the East, when the maintenance of political

control over a wide area was seen to depend on rapid and frequent communication. The postal service of the Persian Empire under the successors of Cyrus the Great is the first great example. The Roman Empire brought the official postal service to a high standard that was maintained until the collapse of the Western empire.

During the Middle Ages such postal services as existed were maintained by the universities or by the guilds of merchants. With the Renaissance the need for private communication forced itself upon the notice of the governments of the day. There were three motives underlying the development of governmental policy: the desire to ensure an official control or censorship, mainly of international correspondence; the need for additional sources of revenue; and the wish to provide an efficient service.

1. Early Proclamations.—In England, the first motive was prominent in a proclamation of Queen Elizabeth I dated 1591, which prohibited the carrying of letters to and from "the Countreys beyond the seas" except by messengers duly authorized by the Master of the Posts. This was directed against the private posts maintained by the foreign merchants in London and seems to have been effective at the time in ending them. In 1609 James I extended the prohibition to the inland post. The importance of state control emerged again during the protectorate, and in Oliver Cromwell's Post Office Act of 1657 stress was laid on the importance of a centralized post office as a means not only of promoting trade but also of discovering and preventing "many dangerous and wicked designs which have been and are daily contrived against the peace and welfare of this Commonwealth, the intelligence whereof cannot well be communicated but by letter of script." (Postal censorship, long discontinued, was briefly revived during World Wars I and II.)

The post office as a public service under the royal monopoly was first constituted in 1635 by a proclamation of Charles I "for the settling of the Letter-Office of England and Scotland." The task of setting this up was given to Thomas Witherings, the "postmaster of England for foreign parts." Witherings organized posts that traveled night and day on each of the great post roads, covering a minimum distance of 120 mi. a day, with branch posts working to and from the post towns on the way. A letter could be thus sent from London to Edinburgh and a reply received in six days—an enormous improvement on anything previously attempted. A regular tariff of rates was established, based on the "single letter," i.e., one sheet of paper. This method of charging and the zone system of postage rates remained until the reforms of (Sir) Rowland Hill. Witherings' rates for the single letter ranged from 2d. for 80 mi. in England to 9d. from England to Ireland; and there was an additional charge for use of the branch posts.

In 1653 the government decided, for revenue purposes, to let the posts out to farm, i.e., have them handled by a private organization that paid the government £10,000 per year for the privilege of carrying on the business. This arrangement was continued until 1716. The revenue of the post office, however, was not considered simply as a contribution to the general expenses of government. In 1663 it was settled on the duke of York and his male heirs, reverting to the crown in 1685 on the accession of the duke as James II.

The proclamation of 1657 marked the first attempt to regulate the postal service by statute. It affirmed a government monopoly, provided for the post of postmaster general, regulated the treatment of letters brought by private ship, and prescribed the rates of postage, both inland and foreign.

In 1653 Louis XIV of France had authorized the establishment of a local post in Paris at a charge of one sou. Profiting no doubt by this example, a London merchant, William Dockwra, brought into existence in 1680 the London penny post as a private business enterprise. A rate of 1d., to be prepaid, was charged on all packets up to one pound in weight, the packets being insured up to £10. Several hundred receiving offices were opened, from which an hourly collection was made, the letters being brought into six central sorting offices. There were 4 to 8 deliveries a day in the greater part of London and 10 or 12 in the business centres. There was also a daily delivery, for which an additional 1d. was charged, to

places 10 or 15 mi. from London. For some time Dockwra struggled with serious financial difficulties, and no sooner had his penny post begun to show a profit than the duke of York asserted his monopoly. Dockwra was condemned to pay damages and his undertaking was incorporated in the general post office.

Another Post Office Act was passed in 1711. This united the post offices of England and Scotland, which had been separated in 1695, regulated the postal service in the West Indies, New York, and the other British colonies in America, prohibited post-office officials from taking part in politics, and increased substantially the rates of postage to provide for the expenses of the War of the Spanish Succession.

A difficult administrative problem had now arisen—that of the crossposts, or letters exchanged between one town and another without passing through London. In 1719 Ralph Allen, postmaster of Bath, offered to farm them at a rent half as large again as the current net receipts, and he managed them successfully for nearly 50 years at a constantly increasing rent. The net revenue of the post office increased by two-thirds between 1724 and 1769.

2. First Mail Coach, 1784.—The later years of the 18th century were marked by a great development of the main roads and a consequent improvement in speed of communication. A proposal to establish regular mail coach services was brought to the personal notice of William Pitt, who saw its merits and ordered its adoption. The coaches were all to leave London at the same time—8 P.M.—and to return together as far as possible. The security of the mails

BY COURTESY OF H. M. POSTMASTER GENERAL

ORIGINAL MAIL COACH USED ON THE FIRST COACH ROUTE BETWEEN LONDON AND BATH IN 1784

was to be provided for by armed guards. The first mail coach was established between London and Bath in 1784, and within two years coaches were running to Norwich, Nottingham, Liverpool, Manchester, Leeds, Milford Haven, Holyhead, Exeter, and other places. By 1797 there were 42 mail coach routes in operation. Examples of times taken were: London to Holyhead 27 hr., to Edinburgh 43 hr., to Falmouth 29 hr.

The development of the post was hampered by the need to obtain revenue to finance the war with Napoleonic France, and the rates of postage were periodically increased until in 1812 they were higher than ever before. These high rates were retained for 25 years after Waterloo, and when Rowland Hill published his pamphlet on uniform postage in 1836 he had behind him a substantial volume of public discontent. Hill argued that the postal administration was conducted on principles which were in effect an obstacle to the development of postal business. The principal features of his scheme were: the abolition of postage rates based on distance and the number of sheets, and substitution of rates based simply on weight; the prepayment of letters by postage stamps; and the adoption of a uniform minimum rate of 1d. for a one-half ounce letter. (For information on stamps see PHILATELY.)

3. Rowland Hill's Success, 1840.—It was only after four years of agitation and parliamentary inquiry that uniform penny postage was finally established in 1840. This was the most signal service Great Britain rendered to the cause of postal progress, and from the point of view of developing social relations and business com-

munications it was an unqualified success; the standard established was one which it became the ambition of the rest of the world to attain. This success, however, had to be paid for in another way. Post-office revenue fell by two-thirds between 1839 and 1840, and it took 35 years for it to recover to the 1839 level.

For several years after the introduction of uniform penny postage the post office introduced no more reforms and devoted itself to developing its existing services. The effect of the new rate on the volume of correspondence was immediate and continuous. In 1840 the number of letters posted was more than double that posted in the previous year. In ten years it had almost quadrupled, and by 1870 had increased tenfold.

The initial weight of one-half ounce for a 1d. letter adopted by Rowland Hill was doubled in 1871 and raised to four ounces in the Jubilee reform of 1897. World War I brought about the abolition of penny postage 75 years after its establishment. Since then the rate has altered from time to time as costs and circumstances have changed.

4. Newspapers.—In 1840 newspapers were by statute carried free of postage. This, however, was not equivalent to the free postage given on a more or less extended scale in other countries; from the time of Queen Anne all newspapers had contributed to the revenue through the stamp duty which was levied on every copy. This continued until 1855 when the duty was made optional, the privilege of free postage being continued for such newspapers and even periodicals as chose to pay the duty; other newspapers were forwarded by book post (*see* below). In 1870 the position was altered by an act of Parliament which established a small flat rate, irrespective of weight, for each publication registered at the general post office as a newspaper; the privilege of registration was granted only to papers that were published at intervals of not more than seven days and complied with certain specified conditions. The principle of a flat rate irrespective of weight was abandoned when the rate was increased in 1915, but it is still the practice to charge separately for each copy, however many are sent together.

5. Book (Now Printed Paper) Post.—The first special rate of postage introduced after 1840 was the book post, instituted in 1848. This was intended to benefit education and literature and was fixed at 6d. a pound. By the time the minimum charge was reduced to ½d. per 2 oz. in 1870, circulars had been admitted at the special rate. Various changes have taken place since, in both the rate and the scope of the service, which now embraces practically all kinds of commercial documents wholly or partly printed, as well as books and magazines.

6. Postcards.—The Austrian post office introduced the inland postcard in 1869. It won immediate success and was adopted in Great Britain in 1870, the postage rate being originally ½d. For many years only officially provided postcards were allowed. The admission of private cards paid at the same rate, first allowed in 1894, encouraged the development of the picture postcard.

7. Sample Post.—This classification was established in 1863 to allow a special rate to bona fide trade patterns and samples. The rate fixed at that time was 3d. for 4 oz., rising to 1s. 6d. for 24 oz., the maximum weight then permitted. Because of the restriction of the sample post to bona fide samples, it was always found in practice extremely difficult to operate; it was abolished three times only to be reinstituted each time.

8. Parcel Post.—An international parcel post was established by the Postal Union Conference of Paris in 1880. In Great Britain an inland parcel post service was started in 1883; the maximum weight for parcels was then seven pounds with a scale of charges from 3d. to 1s. according to weight. The maximum weight was raised to 11 lb. in 1886, to 15 lb. in 1935, and to 22 lb. in 1963. Numerous changes have taken place in the rates over the years.

9. Registration.—A parliamentary commission in 1838 recommended a uniform system of registration, but the reform of postage rates caused the postponement of the scheme and it was not until 1841 that a general registration system came into being, and then only in an attenuated form, no responsibility being accepted in the event of loss. The service was not attractive, but it was not until 1878 that compensation was introduced for loss and extended in

1886 to cover damage. The liability accepted was originally £2, but was gradually increased. The minimum registration fee in the inland service now covers compensation up to £20, and the maximum fee compensation up to £400. The service is extensively used for both letters and parcels.

10. Recorded Delivery.—This service, which is available for most classes of inland postal packets except parcels, was introduced in 1961 as a cheaper alternative to registration for items such as legal documents which have little intrinsic value but for which the sender may wish to have a record of posting and delivery. A receipt is given at the time of posting and a signature is taken from the recipient on delivery. A recorded delivery packet is not permitted to contain articles exceeding £2 in total value (the limit of compensation in the service); and some articles, such as money or jewelry, are prohibited.

11. Philatelic Bureau.—This bureau was set up at post-office headquarters in 1963 to provide (1) a central point from which all stamps on sale at post offices would be available at face value by post for customers in Great Britain and abroad (including, for example, regional stamps and phosphor-lined stamps on sale only at certain offices); (2) specialized services for philatelists (including, e.g., first day cover services, credit accounts, regular mailing list facilities); (3) special publicity and exhibition facilities designed to promote interest in British stamps at home and abroad.

12. Household Delivery Service.—By this service, introduced in 1964, all forms of advertising matter, of about postal size, unstamped and unaddressed, enveloped or unenveloped, are delivered to all delivery points in any selected delivery area. Items in any posting must be identical and conform to certain conditions of weight (not more than four ounces), size and shape (generally rectangular without protrusions). Charges vary from £5. 5s. per 1,000 for items weighing up to 2 oz. for delivery in towns to £11. 11s. per 1,000 for items weighing between 2 oz. and 4 oz. for delivery in rural areas.

B. MAILS BY RAIL

1. Letter Mails.—The first important railway passenger service in England was established between Manchester and Liverpool in 1830. Mails were carried from that year but the first Conveyance of Mails Act was not passed until 1838. Under this act, the provisions of which were, in essentials, perpetuated in the Post Office Act 1953, the postmaster general was empowered to call on the railway companies to convey mails and guards in all trains, and, if required, to provide a whole car for the purpose of sorting letters. The only financial provision in the act was that the railway companies should receive "reasonable remuneration" for their services; any disputes which could not be settled amicably were to be referred to arbitration.

Even at this early stage it was seen that the value of the railways to the post office lay not only in their speed but in the facilities they afforded for doing in transit the work of sorting letters. The first traveling post office ran between Birmingham and Liverpool in 1838. Later in the same year another traveled between London and Preston. The speeds on the early railways were comparatively slow. The journey from London to Birmingham took five and a half hours, and from London to Manchester or Liverpool nine and a half. These times were, however, less than half those taken by the London mail coaches, the last of which was withdrawn in 1840. In spite of the great improvements they offered in the mail service, the railways entailed a much heavier cost on the post office than the mail coaches, and for several years after their establishment the companies and the post office disagreed on the question of payment.

At the outset mails not carried in a traveling post office were dispatched by train in charge of a post-office guard. The system worked well enough for the small mails of the 1830s; but the great growth in the number of letters which followed the introduction of penny postage soon made this arrangement inconvenient and costly, and in 1848 statutory powers were obtained under which the railway companies were obliged to convey mails by train in charge of their own guards; this remains the normal procedure for the great bulk of the mails sent by railway.

Far-reaching as are the statutory powers of the postmaster general with regard to the railways, in practice they are not invoked; the arrangements with the railway authorities are settled by negotiations and are laid down in contracts. An important requirement of the contracts is the running of certain trains at times convenient to the mail service, and these times cannot be altered without the consent of the postmaster general. Great Britain is covered by an intricate network of mail trains providing direct and speedy communication between all parts of the country. On the route to Scotland there is a special train devoted entirely to the post office, running nightly in each direction between London and Edinburgh, Glasgow, and Aberdeen. This successor of the original London-Preston traveling post office is the trunk main line mail service of Great Britain. A similar special train runs in each direction between London and Penzance. In all other cases the mail trains carry passengers as well as mails.

2. Parcels.—The Post Office Parcels Act of 1882 provided that the post office should pay to the railway clearinghouse 55% of the postage received on all parcels conveyed by railway, the distribution of the sums thus received among the railway companies being undertaken by the clearinghouse. This arrangement enabled the post office to maintain the principle of flat rates of postage according to weight for the whole country.

It soon became evident that for short distances it was possible to convey parcels by road at a lower cost than the payment to the railway companies provided under the act, and, very shortly after the establishment of the parcel post, parcel coaches were established by the post office. These road services developed further with the coming of the internal-combustion engine. The higher speed and greater capacity of the motor van made a large extension of the coach system practicable, and by the outbreak of World War I parcels were being carried by road during the night between large towns up to a distance of 120 mi.

Following fresh negotiations with the railway companies, it was enacted by the Post Office Parcels Act of 1922 that the share of the postage payable to the railway companies should be reduced to 40%, the post office for its part agreeing that the railway companies should be entitled to claim a revision of the basis of their remuneration if the number of parcels conveyed otherwise than by railway exceeded 10% of the total number transmitted by post. Under these arrangements, many of the road services were terminated as being no longer remunerative. Beginning on Jan. 1, 1951, the arrangements between the railways and the post office were based on a contract between the parties which superseded the arrangements laid down in the Post Office Parcels Acts. While the bulk of mail was still carried by rail, changes in the pattern of both postal and rail services led to a reversion to conveyance by road in certain areas. A large-scale experiment for the conveyance of parcels by road began in East Anglia in 1963.

C. MAILS BY SEA

The first regular government mail packet service was established during Charles I's reign between Holyhead, Wales and Dublin, Ireland. At that period, however, foreign communications were of greater postal importance than those with Ireland, and, when a postmaster for foreign parts was appointed, it became incumbent on the post office to provide a regular means of communication with foreign countries. In 1633 Witherings, who subsequently reformed the inland post, began his career by establishing efficient and regular communication with France by hired boatmen engaged to carry the mail between Dover, Eng., and Calais, France.

For the next 50 years the service appears to have been somewhat unsatisfactory and development slow; but in 1666 a regular service was established by government packet between Harwich and the Netherlands, followed in 1690 by a service from Falmouth to Corunna, Spain, and in 1703 by a weekly service from Falmouth to Lisbon, Port.

The growth of British overseas possessions in the 18th century led to further developments. After an unsuccessful attempt at the beginning of the century, regular packet service from Falmouth to the West Indies was established in 1702; packets also ran to North America and by the end of the 18th century they served a great

part of the world. The packets themselves were small, being only 150 tons, but, according to a report of 1788, they were considered fit to go to any part of the world.

The next important event in the history of the packets was the introduction of the steamship. Steamship communication with Ireland was established in 1818, and in 1821 a mail packet of 205 tons burden was put on this service, being followed in the next year by a steamship on the Dover-Calais route. It soon became evident, however, that mails could be carried more advantageously by private companies than by the government, and in 1838 the principle of inviting tenders for the mail service from private companies was introduced.

In the earlier part of this period the government definitely adopted the policy of subsidizing steamship companies in order to establish regular communication on routes where ordinary traffic would not have justified the requisite expenditure, and to ensure the provision of a better type of vessel. The first contract was made with Samuel Cunard in 1839 for a subsidy of £55,000 a year and was speedily followed by others. The subsidy policy, however, proved in practice costly; the expenditure in 1853, when it became the subject of a parliamentary inquiry, had reached the considerable sum of £825,000. Thereafter the principle of the subsidy gradually disappeared; its object had been fulfilled by the establishment of such far-reaching mail services as those of the Peninsular and Oriental Steam Navigation Company, the Royal Mail Steam Packet Company and the Cunard White Star Line.

The use of noncontract ships for mail service was, in fact, a return to an earlier epoch in the history of the overseas mail service. The government packets in the 17th and 18th centuries were far from covering the whole field; for example, Africa and Asia were never touched by them, and for correspondence to and from a great part of the world the only means of transport was the private ship. The post office for a long period made only a feeble attempt to secure control of this means of communication. The measures taken were not effective, and as late as 1827 certain coffeehouses, which had customarily kept bags for the acceptance of overseas mail, were still collecting letters in defiance of the law. The general improvement in the postal service, and in particular the effective measures taken to establish regular mail services by private ships whenever such a course was advantageous, gradually abolished the incentive to forward letters by other means than through the post office.

D. MAILS BY AIR

The history of airmails in Great Britain began in 1911 when, to celebrate the coronation of King George V, an airmail service was run between Hendon and Windsor. Twenty-one trips were made and thousands of postcards and letters were carried; but the service was irregular and did not hold out much promise of the development which came a few years later as a result of the great progress made by aviation during World War I. After the Armistice an experimental service between Folkestone and Cologne, Ger., was set up for the benefit of the army of occupation; it was followed in Nov. 1919 by a regular service between London and Paris, on which the air fee, originally fixed at the high rate of 2s. 6d. an ounce in addition to postage, was soon reduced to 2d. an ounce. Other regular services to European countries followed (including an air parcel service between London and Paris in 1921); airmail services spread further afield, the England-India service begun in 1929 being the first stage in extending airmail services from the United Kingdom to the rest of the Commonwealth of Nations.

During the 1930s the United Kingdom post office introduced in the service to many European countries the so-called "all-up" system, whereby first-class mail was sent by air at normal rates of postage whenever it would thereby secure earlier delivery. An all-up system at a postage rate of 1½d. per ½ oz. was also introduced on the Commonwealth air routes to the Union of South Africa and Australia. During this period regular airmail services over internal routes were also begun. In some instances special air fees were charged; in others the mail was carried at the ordinary postage rates.

The outbreak of World War II led to the suspension of many airmail services and the reintroduction of air fee services on other routes. Aircraft capacity was at a premium and, to meet the urgent needs of military personnel in particular, an airgraph service, both from and to the United Kingdom, was introduced in 1941. Airgraph messages (known in the U.S. as V-mail) were written on special forms which were handed in at post offices. The forms were photographed on a strip of film 100 ft. long by 16 mm. wide. The film strip, containing 1,700 messages and enclosed in a cardboard container, weighed only 5½ oz., whereas a similar number of letters by ordinary post would have weighed about 50 lb. After being forwarded to their destination by air, prints prepared from the photographed messages were delivered to the addressees in the ordinary way. More than 350,000,000 airgraph messages were conveyed during the four years in which the service operated. A lightweight air letter service between military personnel abroad and correspondents in the United Kingdom was also introduced in 1941-42.

At the end of the war airmail services were reintroduced throughout the world, and it became possible to send both first-class and second-class mail from the United Kingdom to practically any place in the world. The air letter form was retained as a specially inexpensive form of airmail service and this type of communication was internationally recognized by the Universal Postal Union in 1952 under the name of "aerogram." The all-up service to European destinations was reintroduced and extended, but the high cost of air transport in the postwar period precluded its introduction on the intercontinental routes. Air parcel services were introduced to most destinations.

Inland air mail services were also extended after the war and by 1961 links between London, Manchester, Edinburgh, Glasgow, and Belfast and services to the Scottish Islands, the Isle of Man, and the Channel Isles were playing a valuable part in speeding the mail.

E. POSTAL MECHANIZATION

From the early part of the 20th century the post office interested itself in the development of mechanical aids to assist with the handling of the mail. Between World Wars I and II many conveyor systems were introduced for moving mail between handling points in the larger sorting offices; and the letter-sorting office at Mount Pleasant, London, became one of the most highly mechanized in the world. In 1927 the London post-office underground railway was opened. This railway, running between Liverpool Street Station and Paddington Station, was 6½ mi. long and linked seven main post offices. In the first half of the 1960s the railway carried about 45,000 bags of mail a week.

Shortly before World War II the post office turned its attention to the possibilities of mechanizing the sorting of letters. The design of suitable machinery for this purpose proved to be very difficult because of the great variety of sizes, shapes, and weights of letters and to the short time available for sorting them. Most mail is posted at the end of normal office hours and has to be dispatched to its destination in time for delivery early the next morning.

Work on postal mechanization was suspended during the war but restarted in 1946. Post-office engineers soon produced the prototype of a letter-sorting machine which an operator could use to sort letters at about twice the speed of hand sorting. A unique feature of the machine was its ability to adjust its speed to the speed of the operator. By the early 1960s a number of these machines were in daily use at offices in different parts of the country.

Other machines were developed to prepare mail for sorting. They could separate letters from packets, separate small letters from large letters, date-stamp the letters, and put them into stacks with the addresses all facing the same way and with the postage stamps in the same corner of the stack. They could also separate lower paid (printed paper) items from the fully paid letters. To help them carry out these tasks a phosphorescent substance was incorporated in the postage stamps sold in the area where the machines were in use.

In 1960 the first experimental fully automatic sorting machine was installed for trial at Luton, Bedfordshire. About the same

time the post office also started a local experiment in which the public was asked to use a postal code—a condensed form of postal address—to facilitate the mechanized sorting of letters.

In 1959 the post office opened in Leeds a mechanized parcel sorting office employing a sorting machine controlled by push-button keyboards. Improved machines, similarly controlled, were installed at Preston in 1962 and at Worcester in 1963. Large sorting offices adjacent to railway stations were sometimes linked by conveyor systems providing continuous transport for mail bags.

F. MISCELLANEOUS SERVICES

In addition to the general postal service, special facilities have been made available for speedier or more convenient delivery. The most important is the express delivery, established in 1891. The most useful variety of express delivery is perhaps that by which a letter or packet may, when messengers are on duty, be dispatched by special messenger to its destination on payment of a mileage fee. Living animals are accepted for express delivery if a suitable receptacle or lead is supplied and provided the sender takes precautions to safeguard the messenger from injury. A fur-

BY COURTESY OF H. M. POSTMASTER GENERAL

SELF-SERVICE POSTAL CENTRE OUTSIDE THE TRAFALGAR SQUARE BRANCH POST OFFICE, LONDON, SUPPLYING STAMPS, POSTAL ORDERS, AND STAMPED STATIONERY

ther service provides for the immediate delivery, at the request of the sender, of letters or parcels received at the post office in the ordinary mails; the same service is provided at the request of an addressee who is expecting an important letter.

When a quicker transmission is required than that of ordinary mail, the Railex service provides for letters to be accepted at many post offices for conveyance by messenger to the railway station for dispatch by the next available train. A messenger will meet the train and deliver the packet to the addressee.

When correspondence is regularly required earlier than the normal delivery time, anyone may rent a private post office box from which he or his messenger may obtain his letters and parcels on application. Large users may have their correspondence or parcels collected free by the post office; and, when postings are so large that the application of postage stamps becomes inconvenient, postage may, subject to certain conditions, be paid in cash. Another method of avoiding the use of postage stamps is by means of postal franking machines, used under licence from the post office. These machines impress the correspondence with a red franking stamp which is accepted as the equivalent of a postage stamp. Each machine is provided with a meter, which is set from time to

time at the post office, postage being prepaid in cash on the number of impressions which the meter is set to register.

There are two services—business reply service for letters, cards, etc., and postage forward parcel service—where postage has not been prepaid by senders but is charged to the special deposit accounts of addressees when delivery of the items is made. These services operate under licence, an additional fee is charged and a special envelope or label has to be used.

G. THE POST OFFICE AS BANKER

1. Savings Bank.—The British Post Office Savings Bank was set up in 1861, as a result of legislation introduced by William Ewart Gladstone. The object was to encourage thrift among poorer people, and limits were therefore set to the amount of money which could be deposited. The maximum amount which may be deposited by any individual is £5,000. Interest is allowed on complete pounds at the rate of $2\frac{1}{2}\%$ and is added to the balance at the end of each calendar year. All accounting is centralized, but a depositor may pay in or withdraw money at any of the 20,800 post offices in the country at which savings bank business is transacted. On certain conditions, a withdrawal on demand up to £10 at a time may be made at any savings bank post office. To make larger withdrawals a notice has to be sent to headquarters and an authority to pay is issued to the office named by the depositor. Within certain limits withdrawals may be made by telegram. All deposits are handed over to the national debt commissioners, by whom they are invested for the Post Office Savings Bank Fund. The Post Office Savings Bank has enjoyed increasing popularity through the years.

2. Insurance and Annuity Business.—In 1864 the post office was authorized to set up an insurance and annuity business through the Savings Bank, but this business was never of more than moderate dimensions. Insurance business was discontinued in 1928 and the sale of government annuities ceased in 1962.

3. Post-Office Stock Register.—A much more successful development was instituted in 1880 when facilities were given to depositors in the Savings Bank to purchase government stock up to a limit of £300. A simple method of purchase was devised at a low rate of commission, and dividends were credited to the purchaser's savings bank account. From 1915 it was no longer necessary to be a savings bank depositor in order to hold stock through the post office, nor did dividends need to be paid into a savings bank account. During World War I the machinery proved of great value to the government in making it possible for the small investor to purchase or subscribe to government stock. For many kinds of government stock there was a post-office as well as a Bank of England issue, and subscriptions could be made at most post offices. The most outstanding development of the post-office register occurred during World War II when a special issue of defense bonds, restricted to the post-office register, was introduced. The bonds made an appeal to all classes; although initially a maximum of £1,000 was set to each holding, the peak holdings of the bonds exceeded £1,000,000,000.

4. Savings Certificates.—A further simple and popular method of investment managed by the post office is the national savings certificate. Originally issued in 1916, it proved attractive to all classes during World War I as a means of helping the war finance, and at the end of 1918 the value of the certificates held exceeded £200,000,000. By the mid-1960s the figure was more than ten times as great.

The early certificates were based on a unit of £1, which was the value given to the certificate after it had been held for a number of years. The purchase price of the certificate varied from time to time according to the rate of growth and the number of years before the value reached £1. Interest on the certificates is not paid separately but is included in the value when the certificate is repaid. Certificates are repayable at any time after a few days' notice. The accrued interest is free from United Kingdom income tax. Limits are imposed on the number of certificates which may be held by one individual.

5. Premium Savings Bonds.—Premium savings bonds, issued through the post office by the Treasury, were put on sale in 1956.

They differ from other securities offered to the small saver in that instead of earning interest they have, after a qualifying period of a few months, chances of winning cash prizes free of U.K. tax. Drawings for prizes are held monthly; each unit bond gives the holder one chance in every drawing for which it qualifies. A novel feature of the scheme was the method of drawing winning bond numbers electronically and entirely at random by E.R.N.I.E. (Electronic Random Number Indicator Equipment) which was built specially by the post-office engineers.

6. Savings Stamps.—Various aids have been introduced from time to time to encourage the saving of quite small sums; e.g., home safes (until 1942) and slips to which postage stamps could be affixed (until 1959); but the method of national savings stamps became the main as well as the most popular method. The stamps can be used for the purchase of savings certificates, defense bonds, and premium savings bonds, or for deposit in the savings bank, but they can also be cashed freely at post offices.

7. Money Orders.—The original purpose of the "money letter" plan when it was introduced toward the end of the 18th century was to prevent the theft of money carried in letters. There was some doubt whether such a service could be established by the post office under its existing powers, so by a curious compromise certain officers of the post office were allowed in 1792 to set up a service on their own account, the cost of advertising it being borne by the postmaster general. The money order service was taken over by the post office in 1838. The rates of commission charged to the public varied from time to time, and the maximum for which a single order may be issued increased to £50. Notwithstanding competition of the less expensive postal order (see below), the money order appeals because of the security afforded by the special feature of the service—the advice note which is sent to the office of payment and against which the order is checked before payment.

The overseas money order service came into being in 1856 when arrangements were made for sending orders to Britain from army post offices at Constantinople, Scutari, Alban., and Balaklava, Crimea, this plan being extended to Gibraltar and Malta the following year. The first two-way service was with Canada in 1859, and services with other colonies soon followed. In 1868 the first foreign money order service was started with Switzerland. The service was extended gradually to cover most parts of the world in which an inland money order service operated. A telegraph money order service was started with Germany in 1898 and was extended to many other countries. Since 1939 the overseas money order service has been subject to exchange control regulations.

8. Postal Orders.—A reduction in 1871 of the commission charged on money orders under £1 was followed by an increased demand for the low-value orders, and by 1875 the service was being run at a loss. The comparatively high charges which would have been necessary to avoid this loss caused the post office to consider the alternative of introducing a new method of remittance for smaller amounts which would dispense with the advice note, an expensive feature of the money order service. As a result the postal order (originally styled postal note) was introduced in 1881. These orders were for fixed denominations up to 21s.; after 1951 orders for £2, £3, £4, and £5 were added to the range. Odd amounts can be made up by attaching postage stamps. The orders must be made payable to a particular person, preferably at a particular office, and can be cleared for payment through a bank. The simplicity, low cost, and convenience of the postal order made it an immediate success. Great use is made of this form of remittance in connection with football pools and newspaper competitions.

The convenience of the postal order soon led to a proposal to extend its use, and in 1903 all dominions, colonies, and dependencies were invited to participate in a scheme for making postal orders available for remittances to and from the United Kingdom, between one part of the empire and another, and within the participating country. Most of the Commonwealth, with the notable exceptions of Australia and Canada, are part of this scheme.

H. POST-OFFICE AND SOCIAL SERVICES

One of the most striking developments of post-office activities in the 20th century has been the assignment to it of functions

which have no connection whatever with the primary purpose of the post office but which rely on its widespread network of local offices having day-to-day financial dealings with the public. This development began with the use of the post office for the collection of local or national revenue by means of licence duties. For example, dog, gun, and game licences are available at most post offices and motor vehicle licences (renewals) at selected post offices.

This is, however, a comparatively small item of business and is far exceeded by business connected with the social services. When the Old Age Pension Act of 1908 came into operation the post office became the paying agent. This arrangement was extended to payments under the Widows', Orphans' and Old Age Contributory Pensions Act of 1925 and under the National Insurance Act that came into operation in 1948. Similarly, war pensions, service allowances, supplements to pensions, and family allowances are paid by the post office.

A considerable number of stamps are sold for other than postal purposes. Certain inland revenue duties may be paid by postage stamps (e.g., receipt duty); in addition, the post office has long assisted the inland revenue authorities by selling such inland revenue and fee stamps as are in general use. There is also a large sale of stamps for the various state insurance schemes culminating in the National Insurance Act, 1946. The post office also sells broadcast (sound and television) receiving licences. Records are maintained of the persons who hold such licences and steps are taken to ensure that the licences are renewed as necessary.

I. POSTAL STAFF

The bulk of the post-office staff enjoys the usual civil service conditions of permanence of employment and pensionability. The clerical and professional staff generally belong to grades common to the civil service as a whole. The manipulative staff—postmen, telegraphists, telephone operators, and postal and telegraph officers—are recruited either by interview and selection or by competition. Members of the manipulative staff have opportunities for advancement and promotion to higher ranks, including some appointments in other civil service grades. Pay and conditions of service are settled generally by negotiations with the staff associations or, failing agreement, by awards of the civil service arbitration tribunal, subject to the overriding authority of Parliament. (The Post Office Act, 1961, set up a new financial basis for the post office as a whole by creating and placing under the postmaster general's control a self-contained fund into which all income would be paid and from which all expenses would be met.)

The difficulties which trade unionism met in outside employment were reflected in the history of the postal staff, and it was not until 1899, after two partial strikes, that the duke of Norfolk as postmaster general consented to receive representations from the Postmen's Federation. Thereafter many associations were formed in the post office covering the various grades of staff. In the mid-1960s there were about 20 separate associations officially recognized.

Since 1920 general questions common to the post office and the rest of the civil service have been discussed on the national Whitley Council (see INDUSTRIAL RELATIONS), but the post office has its own headquarters departmental councils (working largely through smaller joint committees) to discuss general matters affecting the staff, and local committees in head post offices, etc., to discuss local matters. This machinery has in no way superseded the functions of the separate unions, which continue to negotiate independently on matters such as wages.

The Trade Unions Act of 1927 forced the post-office unions to sever their connections with the Trades Union Congress, but, with the passing of the Trade Disputes and Trade Unions Act of 1946, some of the unions affiliated with the T.U.C. (R. Gz.)

II. UNITED STATES

A. HISTORY

"Neither snow, nor rain, nor heat, nor gloom of night stays these couriers from the swift completion of their appointed rounds." So wrote the Greek historian Herodotus (c. 430 B.C.) in describ-

ing the mounted couriers used by King Xerxes of Persia. Although the Post Office Department does not have an official motto many people have come to consider the above inscription, which appears on several post-office buildings throughout the U.S., the official motto of the letter carrier.

The first postal system in the United States was legalized in 1639 by the General Court (colonial legislature) of Massachusetts. The ordinance directed that all mail brought from overseas was to be left at the home of Richard Fairbanks in Boston, who would have it transmitted to its destination. Fairbanks was allowed one penny for the transmission of each letter. In 1672 Gov. Francis Lovelace of New York established a monthly postal service between New York and Boston over what later became the Boston Post Road—U.S. Highway No. 1. In 1683 Gov. William Penn of Pennsylvania established a post office in Philadelphia where Henry Waldy, the first postmaster, was authorized to send mail weekly between Philadelphia and New Castle, Del., and to supply the riders with horses.

In 1691 Andrew Hamilton of Edinburgh, Scot., was appointed by the British crown as postmaster general for the American colonies, and the first advance toward establishing an organized intercolonial service was made on Feb. 17, 1692, when a patent was granted to Thomas Neale to establish post offices in North America. An office was established at Philadelphia and rates were fixed for sending mail to most of the colonies, but receipts did not cover expenses and in 1707 the government purchased the rights.

In 1737 Benjamin Franklin was appointed postmaster at Philadelphia and later (in 1753) became co-deputy postmaster general of the British colonies in North America. He served in this office until 1774, when he was dismissed by the crown because of his sympathies with the cause of the American colonists. The next year, on July 26, 1775, Franklin was appointed head of the American postal system by the Continental Congress at a salary of \$1,000 a year; he served until Nov. 7, 1776. To Franklin, in great measure, belongs the credit for establishment of the U.S. postal system. He increased the number of post offices, introduced stagecoaches, started a packet service to England, and put the service on a sound financial basis.

The federal Constitution drafted in 1787 gave to Congress authority "To establish Post Offices and Post Roads." During his first term as president, George Washington on Sept. 26, 1789, appointed Samuel Osgood of Massachusetts to serve as postmaster general. At that time the postal service was part of the Treasury Department and it remained so until 1829, when Andrew Jackson invited his selection for postmaster general, William T. Barry of Kentucky, to become a member of the president's cabinet; it was not until June 8, 1872, that Congress passed a law making the Post Office an executive department of the government. In 1789 there were only 75 post offices; by 1901 the number had increased to 76,945, an all-time high; thereafter the number gradually decreased, amounting to about 34,000 in the 1960s. In 1790 there were only 1,875 mi. of post routes; by the 1960s there were more than 2,250,000 mi. of post routes.

As railroads and steamboats appeared on the scene in the 19th century they were utilized to carry mail. Many communities, particularly those in the West, were remote from such means of communication and were served instead by "star routes," so called because they were identified with stars on the Post Office Department's lists. On these routes the mail was not carried by postal employees but by private contractors using horses and wagons. Fraudulent administration of some of these star route contracts cost the U.S. government millions of dollars before it was exposed in the early 1880s. Since that time the Post Office Department has continued to make contracts for carrying mail on star routes and has actually increased the number of such routes as rail service to some communities has been curtailed and improved highways for motor vehicles have been built.

Under the broad powers granted to Congress by the Constitution a vast and important public service was established and developed. Post offices were established as rapidly as possible and speedy transportation of mails was provided, and service was ex-

tended to distant parts of the country. From its small beginnings in 1789 the postal service developed into the largest business in the world. By 1964 the postal service employed approximately 590,000 workers to process and deliver 360 pieces of mail annually for every man, woman, and child in the United States, a total of more than 70,000,000,000 items.

In colonial times the policy was to make a profit from the postal service, but this policy was changed as the nation developed and pushed westward. It was felt that the Post Office Department should render service to the public in all parts of the country—with due regard for cost—but it was maintained that such service should not always be self-sustaining. This policy continued in effect throughout the years and deficits became common. By the mid-1960s the revenues of the Post Office Department exceeded \$4,300,000,000 annually and expenditures amounted to more than \$4,800,000,000 resulting in gross operating deficits of about \$500,000,000.

Post offices are established in every city, town, and village in the United States for the receipt and delivery of mail and for other special services appropriate to the size and importance of the community. These offices, each with a postmaster, are divided into four classes, depending upon their annual receipts. Postmasters of the first three classes are appointed by the president with the advice and consent of the Senate and those of the fourth class by the postmaster general. By 1965 there were 4,439 first-class, 6,845 second-class, 12,929 third-class, and 9,668 fourth-class post offices.

B. EXPANSION OF SERVICES

One of the first major advances in the postal service was the use of adhesive postage stamps for prepayment of postage. Legislation was enacted on March 3, 1847, authorizing the postmaster general to issue stamps, and they were placed on sale in New York on July 1, 1847, seven years after being introduced in England. (See PHILATELY.) The next new service and the first special mail service to be adopted by the U.S. Post Office was the registry system, inaugurated in 1855 to provide for greater security of valuable letters. The registration service began with a simple fee of five cents for each item; it was applicable only to first-class mail and provided no indemnification or liability for loss. This service was later extended to all classes of mail. In 1898 a nominal indemnity, not to exceed \$10, was added and from then on this protective feature was gradually extended.

The establishment of a parcel post system in 1913 raised the question of providing registration for the anticipated avalanche of parcels. It was felt that the burden would be too great for the registration facilities then available. This situation led to the inauguration of a system of insurance designed especially for parcel post mailings. In 1924, when the distinction between third- and fourth-class mail was placed on a weight basis, the insurance service was extended to third-class mail. At first, the maximum indemnity was \$50 but over the years it was increased to \$200. By payment of a small additional fee a return receipt could also be requested by the mailer.

Collect on delivery (C.O.D.) service was also inaugurated in 1913 as an accessory to parcel post. At first, C.O.D. was available only on fourth-class matter, but it was later extended to third-class and to all classes of sealed mail bearing postage at first-class rates. C.O.D. proved to be invaluable to the shipper who did not wish to extend credit and to the buyer who did not wish to make advance payment. This service also included an indemnity feature against loss or damage; a registry service could be obtained on payment of an additional fee.

Special delivery on a limited scale was first offered in 1885. It was simply another manifestation of the public's desire for faster delivery of mail. By payment of an extra fee the sender was assured that his mailing would be dispatched promptly and would be delivered by a special messenger at its destination. Special delivery service is not to be confused with special handling, which was started in 1925 and consists only of expeditious treatment in transit and does not include immediate delivery at office of address. Special delivery is available for all classes of mail; spe-

cial handling is available only for fourth-class matter.

In June 1955, a certified mail service was inaugurated. This service was designed to accommodate senders who, when mailing documents or other items that have no intrinsic value, desired proof of delivery. At the time the certified mail service was established, no-value registered mail was discontinued.

C. TRANSPORTATION AND DELIVERY

In its earliest years, mail in the United States was transported by horseback riders, stagecoaches, and steamboats. The opening of the West and the movement of settlers to new lands broadened the demand for postal service and the advent of railroads in the 1830s introduced a new means of mail transportation.

With the discovery of gold in California in January 1848 and the rush of thousands of people westward, the postal service kept pace by sending mail overland to Monterey, Calif., by way of Fort Leavenworth, Kan., and Santa Fe, N.M.; the first overland mail arrived in Los Angeles in May 1848. The pony express (q.v.), a private enterprise, was inaugurated in 1860 to provide faster mail transportation to and from the Pacific Coast, but with the advent of the telegraph the service was discontinued in 1861.

From 1789 to 1863, letter mail rates did not include city delivery service. Mail patrons had the option of using the service or not, as they saw fit. The carrier collected two cents for the delivery of each letter, and a similar fee for each letter received by the carrier for deposit in the post office. All fees collected were kept by the carrier. In 1858 street letter boxes were introduced so that postal patrons would not have to pay such fees nor have to go to post offices to mail their letters. In 1863 free delivery was inaugurated in 49 cities and 440 carriers were employed the first year. By 1960 there were more than 5,500 communities throughout the country enjoying this service, and the number of carriers exceeded 100,000. Village delivery service was established at certain second- and third-class offices in 1912 and developed rapidly until most such services were consolidated with city services. Rural free delivery (R.F.D.), generally regarded as one of the most far-reaching developments in mail service, was inaugurated on Oct. 1, 1896, when five routes were placed in operation in West Virginia. By 1960 there were more than 31,000 R.F.D. routes serving 34,000,000 persons, and rural letter carriers were traveling more than 1,750,000 mi. daily.

Until 1862 all mail carried on trains was distributed in post offices; in that year the postmaster of St. Joseph, Mo., tried out

BY COURTESY OF U.S. POST OFFICE DEPARTMENT

U.S. HIGHWAY POST OFFICE EQUIPPED TO SORT AND DISPATCH MAIL EN ROUTE BETWEEN STOPS IN RURAL AREAS

a method of sorting and distributing mail on a moving train between Hannibal, Mo., and St. Joseph in an attempt to avoid delays in mail departures for the West. The experiment was successful, and on Aug. 28, 1864, the first officially sponsored test of a railway post-office car was made between Chicago and Clinton, Ia. On Dec. 22 of that year the Post Office Department appointed a deputy in charge of railway post offices and railway mails. This marked the beginning of the railway mail service, later designated postal transportation service.

As early as 1930, officials of the Post Office Department, anticipating the continued decline in passenger train service, prevailed upon Congress to authorize the establishment of highway post offices throughout the country. Operated on the same basis as the railway mail service, the mails on these highway post offices were transported in large bus-type vehicles that were equipped with facilities for sorting, handling, and dispatching mail. The first route, established Feb. 10, 1941, ran between Washington, D.C., and Harrisonburg, Va. By 1960 there were more than 175 highway post offices and the system had proved satisfactory in every respect.

D. OTHER SERVICES

In 1864 the money order system (*see* MONEY ORDER) was placed in operation in 139 post offices, mainly to accommodate soldiers who were desirous of sending money to their homes. The service was extended to foreign countries in 1867. Postal notes, which were placed on sale for the first time at post offices throughout the country on Feb. 1, 1945, as an experiment to determine whether card money orders were feasible, were withdrawn from sale on March 31, 1951. It was found that the method of bookkeeping employed to keep track of postal notes received and sold at post offices was too complicated to make their continuance desirable.

An important addition to first-class mail was the government postal card, first used in 1873. The original denomination was one cent. It was provided as a convenient means of transmitting brief messages at a rate less than that for a letter in an envelope. By the 1960s the Post Office Department was selling 3,000,000,000 postal cards each year. As early as 1852 Congress had enacted special legislation authorizing the postmaster general to provide suitable stamped envelopes to be sold as nearly as possible at the cost of procuring them.

The postal savings system was established in 1911 to provide a convenient and safe depository for savings and to encourage thrift. Eventually it made the Post Office Department a major U.S. savings bank, deposits reaching a peak of almost \$3,400,000,000 in 1947. Mainly because of the 2% limit on interest paid, deposits declined, and in 1966 Congress discontinued the system. The original maximum account of \$500 ultimately reached \$2,500.

The establishment of the parcel post system on Jan. 1, 1913, constituted a major extension of the postal service. It answered the popular demand for an efficient means of shipping small packages. Because transportation cost per mile is an important factor in the shipment of packages, distance was considered in setting parcel post rates. The eight zones established in 1913 have continued to serve as the basis of the graduated rates for parcel post.

E. AIRMAIL

Airmail service was established on May 15, 1918, by the Post Office Department in cooperation with the War Department, which furnished the planes and the pilots; the mails were first flown between Washington, D.C., and New York City, a distance of 216 mi. Great interest was aroused and Pres. Woodrow Wilson left the White House to witness the departure of the first mail plane from the nation's capital.

On May 15, 1919, airmail service was established between Cleveland, O., and Chicago, with a stop at Bryan, O., the first step in what a year later became the transcontinental route linking New York City and San Francisco, Calif. The first transcontinental night flight began at San Francisco on Feb. 22, 1921, and ended at Hazelhurst Field on Long Island, N.Y., 33 hr. 21 min. later. By July 1924 regular 24-hr. transcontinental airmail service was in

operation. With the passing of the pioneering stage, the time had arrived for the Post Office Department to discontinue government operation of the service and turn the airmail routes over to private contractors. This action played an important part in the development of commercial aviation. The funds received by airlines for carrying mail were frequently their most important source of revenue. In fact, the first commercial use of the airplane as a means of conveyance was to carry the mail.

Shortly after completion of the coast-to-coast air route, the postal service awarded its first contract for carrying mail by air to a foreign country. The route ran between Seattle, Wash., and Victoria, B.C., a distance of 74 mi., and the service was inaugurated on Oct. 15, 1920, although it was not until 1927 that regular foreign airmail service was in operation. In 1935 another milestone in overseas air transport was marked with the inauguration of transpacific airmail service from San Francisco to the Philippine Islands by way of Hawaii, Midway, Wake, and Guam. This route was extended to Hong Kong on April 21, 1937, and to Singapore on May 3, 1941. Transatlantic airmail service was inaugurated on May 20, 1939, from New York via Bermuda and Portugal to Marseilles, France. Another route between New York and Great Britain by way of Canada and Newfoundland began operation on June 24, 1941. Direct air service to Africa was made possible by the establishment of a route from Miami, Fla., to the Belgian Congo. After World War II there was a tremendous increase in foreign air transport, and direct airmail service to every continent was afforded by U.S. carriers.

The first airmail rate was established in May 1918 at 24 cents an ounce, including special delivery. By November of the same year the rate was reduced to six cents an ounce without the provision for special delivery. The many changes in postal rates for airmail during the period from the inauguration of the service to 1928 reflected the rapidly changing conditions that surrounded the phenomenal development of transportation by air. By 1928 the rates became stabilized, and thereafter ranged only from five to eight cents per ounce. On April 29, 1947, the 10 cent air letter sheet, available to any country in the world, was made available to postal patrons by the Post Office Department as a convenient economical means of sending communications to foreign lands.

Large metropolitan areas continued to present a problem in dispatching mail to and from the airport. In numerous instances the time saved in sending mail long distances by air was lost by the time consumed in surface transportation. It was thought that the helicopter, because of its ability to land in a small area, on the ground or rooftop, might prove the solution to the problem. Tests of the carrying of mail by helicopter were conducted in the Los Angeles area in July 1946, in Chicago in October 1946, and at New York City in February 1947. As a result, the world's first experimental helicopter airmail service was inaugurated in the Los Angeles area on Oct. 1, 1947, over a route linking communities to the north directly with the airport. Shuttle service between the airport and the Los Angeles terminal annex post office was instituted the same day. The route was expanded until by 1956 it served approximately 50 cities and towns in the Los Angeles Metropolitan Area. Similar service was inaugurated later in other cities.

Domestic air parcel post service was begun Sept. 1, 1948, including parcels weighing more than 8 oz. and not more than 70 lb. Zone rates varied according to the distance flown.

International air parcel post service was inaugurated in 1940 between the United States and Europe, the North Atlantic area, South America and the Pacific area. Air parcel post service became available to more than 60 countries throughout the world. Hundreds of planes flown by U.S. carriers in the early 1960s were operating over 300,000 mi. of foreign routes, transporting in a matter of hours mail that less than 20 years before had taken weeks to deliver.

Late in 1953 the Post Office Department initiated the experimental carrying of regular letter mail by air between New York, Chicago, and Washington, D.C., at no extra charge. European countries had previously pioneered this practice. The new service supplemented, but did not displace, regular airmail. Airmail let-

BY COURTESY OF U.S. POST OFFICE DEPARTMENT

HELICOPTERS PROVIDE FAST SHUTTLE SERVICE OF AIR MAIL FROM AIRPORTS TO METROPOLITAN AND SUBURBAN AREAS

ters were guaranteed transportation by plane but other mail was carried by air only when space was available for it. By 1960 this experimental airlift service had well-defined routes within New England and the eastern Great Lakes region; from Chicago to St. Louis, Mo.; a southwestern network including Texas and Oklahoma and extending westward to Albuquerque, N.M.; a northern Rocky Mountain area centring around Salt Lake City, Utah; and connections between all major cities of the Pacific Coast.

On June 8, 1959, the submarine USS "Barbero," surfaced in the Caribbean Sea and fired a Regulus guided missile carrying 3,000 letters. Within minutes the missile, under remote control, landed at Mayport, Fla. This successful experiment opened up possibilities for future development of a whole new concept in mail transportation.

F. CLASSIFICATIONS OF MAIL

In the early years of the U.S. postal system there was not sufficient diversity of mail matter to require formal mail classification. The act of 1792 recognized only letters, packets, and newspapers as mail matter. Magazines and pamphlets were recognized in 1799 and unbound journals in 1825. Lithographed circulars, handbills or advertisements, and every other kind of printed or other matter was recognized as mailable in 1845. In 1851 bound books were made mailable, with a weight limit of four pounds. In 1861 maps, engravings, photographic prints, photographic paper, letter envelopes, cards, blanks, seeds, and cuttings were made mailable and the weight limit for each was fixed at four pounds. The following four classes of mail were established in 1879:

First-Class Mail.—As letter mail has always ranked first in terms of revenue and number of pieces, letters of a personal or written nature were designated as the "first" class when mail matter was classified in 1863. In the early period, letter rates varied not only on the number of sheets in a letter but also on the basis of the distance the letter was to travel. There was a constant tendency to reduce the number of distance graduations. By 1845 the move to a uniform rate was advanced when the five-zone schedule then in effect was reduced to two zones. Six years later the only distance differential remaining was under and over 3,000 mi. Finally, in 1863 a uniform rate regardless of distance was established.

Since 1879 there have been relatively few changes in the rate structure of first-class mail. Among the most important were the inauguration of the postcard service in 1898; an increase in the weight limit in 1916 from four pounds to the weights applicable to fourth-class matter; and the initiation of business reply cards and letters in 1928. With the exception of a brief period during World War I, nonlocal letters were carried at a rate of two cents an ounce between 1883 and 1932. In 1932 the rate was increased to three cents an ounce, in 1958 to four cents, and in 1962 to five cents an ounce.

Congress vested in the Post Office Department a monopoly in

the conveyance of letters, but did not extend this monopoly to any other class of mail matter.

Second-Class Mail.—Prior to 1863 there was no "second" class of mail as is now known. Separate rates of postage existed for newspapers and magazines, and when additional printed matter was admitted to the mails it was charged the same rate as magazines. With the establishment of three classes of mail in 1863, newspapers, magazines, and other periodical publications came under second-class rates, and other printed matter under third class.

Since 1879 the most important change in the second-class rate structure was the introduction of a distance factor in levying separate charges on the advertising portions of second-class matter. This change took place in 1918, the parcel post zones being used as a basis of a graduated schedule of rates. The rates for the editorial portions of publications have remained relatively stable in spite of the many changes that have taken place in both postal and publishing operations. Eligibility for the second-class privilege has been redefined on several occasions in order to reduce administrative difficulties and help eliminate abuses of a subsidized service.

Third-Class Mail.—Before the "third" class of mail was also established in 1863, circulars, handbills, and other material were charged the same postage rates as magazines. For all practical purposes third-class mail between 1863 and 1879 became a catch-all category. Within the classification was a miscellany of matter, some of which was accorded special rates. With the designation of a fourth class of mail in 1879 some of the matter which was embraced by the former third class was shifted to fourth class. Printed matter other than regular newspapers and periodicals remained third class, while merchandise and other mailable matter became fourth class.

Later the distinction between third and fourth classes was changed from type of matter to a weight basis. First, in 1914 parcels of miscellaneous printed matter, if weighing over 4 lb., were shifted to fourth class; in the same year books over 8 oz. were also placed in fourth class. In 1925, all matter not in the first or second classes weighing 8 oz. or less was placed in the third class and that weighing over 8 oz. in the fourth class; in 1958 the dividing line between third and fourth classes, in terms of weight, was changed from 8 to 16 oz.

The most important change in the third-class rate structure occurred in 1928 when a special "bulk rate" was made applicable to separately addressed identical pieces of third-class matter mailed at one time in quantities of at least 20 lb. or 200 pieces. Facing and separation by states, cities, etc. was required of the mailer.

Fourth-Class Mail.—The "fourth" class of mail was established in 1879, with a single flat rate of one cent per ounce. This rate remained in effect until the major revision that established the parcel post system. By the Parcel Post Act of Aug. 24, 1912, the scope of fourth-class matter was enlarged, and it marked the end of the four pounds weight limit on mail matter. At the start,

in 1913, the weight limit was established at 11 lb. Within a year, in response to public needs, weight limits of 50 lb. for nearer points and 20 lb. for more distant points were established. Later the weight limit was increased to 70 lb., with the limit of size not more than 100 in. in length and girth combined, except at first-class post offices, where the limitations were set at 72 in. and from 20 to 40 lb. the latter depending upon the zone to which the parcel post matter is shipped. Fourth-class mail is the only postal service which by law must be operated on a self-supporting basis.

G. TECHNICAL PROGRESS

In 1953 the Post Office Department instituted a program toward mechanization of post-office operations wherever feasible and economical. Within 10 years many major improvements had been made in postal methods and techniques, especially in the development of industrial processes and machinery for the speedy handling of the mails. Machines had been developed and placed in use at several large post offices that mechanically culled, face-canceled, and sorted letters into 1,000 different separations. Experi-

BY COURTESY OF U.S. POST OFFICE DEPARTMENT

SORTING MAIL AT A METROPOLITAN POST OFFICE

mental equipment was available that would electronically read and sort letters having printed or typed addresses into 80 different separations. Other machines had been developed to sort parcels by state and city of delivery. On Oct. 20, 1960, a major step in the development of a mechanized postal system was taken when the first automated post office was placed in operation at Providence, R.I. The Post Office Department also experimented with facsimile mail whereby anything that could be reproduced on a sheet of paper could be transmitted instantaneously across the continent on microwaves, with the privacy of the message preserved. Facsimile messages were transmitted and received between Chicago and Washington, D.C., at the rate of 10,800 pages per hour, or 3 per second. Tests with facsimile mail were discontinued in 1961 because of the high cost of transmitting messages over private leased facilities.

In 1955 a program of replacement and rehabilitation of obsolete and deteriorated post office buildings throughout the country was launched by the postal administration. The program was implemented largely through the provisions of the Lease-Purchase Act of 1954 and through the Post Office Department's commercial leasing program. The Lease-Purchase Act provided for construc-

tion of post-office buildings by private builders and the purchase of such buildings by the Post Office Department on the installment plan. In addition, private industry constructed several thousand new postal facilities. These facilities were financed by private capital and were leased to the Post Office Department. They remained under private ownership, with the owner paying local real estate taxes.

In 1963 the Post Office Department launched a publicity campaign to persuade users of the mails to include in all addresses a five-digit number known as the ZIP (Zone Improvement Plan) Code. The plan was devised mainly to expedite mail service for organizations sending out large quantities of mail. The first three digits identified the section of the country to which the item was destined and the last two digits the specific post office or zone of the addressee. (L. W. Co.)

III. OTHER COUNTRIES

1. Australia.—Australia's largest business undertaking is the Postmaster General's Department. It began in the colony of New South Wales with the establishment of the first post office in Sydney in 1809. An overland mail service between Sydney and Melbourne was inaugurated in 1838. The first official airmail service was established in 1921, between Geraldton and Broome in Western Australia, and was extended to Perth two years later. By the early 1960s about 100 internal networks linked all the states and there were subsidiary services to the interior, the total route distance being more than 70,000 mi. Most interstate-letter mail is now carried by air, free of surcharge. There are several airmail services every week, bringing Europe and America within a few days' distance by correspondence.

Before federation, each of the six colonies had maintained its own postal, telegraph, and telephone services, but, with the passing of the Post and Telegraph Act 1901, the separate services were combined into one federal organization.

2. Canada.—The postal service dates from the French régime when in 1705 a courier first carried official and private mails between Quebec, Trois-Rivières, and Montreal. The post office was established under the British crown by Benjamin Franklin in about 1763 and formed part of the North American system until the American Revolution. In 1851 the separate Canadian provinces assumed control of their postal services, which were merged into a centralized Canadian post office at the time of confederation.

All domestic mail not exceeding eight ounces in weight and prepaid at the first-class rate is carried by air service provided that this is available and will expedite delivery. Canada's airmail service connects with the United States and world air networks and operates directly to the United Kingdom and various other European countries, Central and South America, the West Indies, Australasia, and the Far East.

3. Federal Republic of Germany.—A law of 1871, which with some changes is still valid, gives the German postal service the exclusive right to dispatch sealed letters and daily newspapers. The service is directed by the federal minister of posts with the assistance of an administrative board. A law of 1924 placed the postal service on the same independent financial basis as a commercial company. By law, the service must defray all expenses from the dues it receives, but in establishing dues it takes into account not only prime costs but also cultural and social factors. Dues for letter mail are graduated only by types and by weight, while parcel dues vary according to weight and the distance carried.

The greater part of the mail is conveyed by rail, most of it being sorted during transit. The federal railways are obliged in return for payment, to include a post wagon (railroad car) with each normal train service. There are no special post trains but a number of fast freight trains consist mainly of post wagons, most of which are owned by the postal service.

An extensive road postal network covers districts not served by railways. Most of the motor vehicles are owned by the postal service, and on about 30 routes they are specially equipped for sorting in transit. There is also a postal transport service; posts

buses convey both mail and passengers and account for about one-sixth of all passenger traffic on bus routes.

Letter mail to remote places in the Federal Republic is dispatched without extra charge through the night airmail network. Airmail with surcharge is dispatched to all other countries through air transport companies.

The federal post maintains a money transfer service (money orders), a money collection service (cash-on-delivery orders), a postal check service, and a post-office savings bank service.

4. France.—The date of the creation of a state postal service in France is generally given as that of the Edict of Luxies promulgated by Louis XI in 1464, but the authenticity of this edict is disputed by some historians. Over the centuries the organization of the service was modified by different sovereigns, always tending to reduce the privileges enjoyed by private messengers and to strengthen the control of the royal power over the postal service. The culmination of this policy was the consuls' edict of the 27th Prairial, Year IX (June 16, 1801), of which the sections establishing the foundations of the postal monopoly are still valid.

The system of leasing out the postal service was maintained until the Revolution. It was abolished in 1792 and the service was raised to the status of a national agency. A law of 1848 fixed a uniform inland postage rate and introduced postage stamps for prepayment.

Apart from the use of balloons for transporting mail from the besieged Paris in 1871, the first experimental air link was effected in 1913 between Paris and Pauillac. Following the creation of the first air transport company in 1918, France was quickly linked with Morocco, Senegal, and South America. Each new company was allotted a certain air space. An inland air service began in 1933 but there was no real network until after World War II.

In the course of the 19th century and the first half of the 20th century, various services were attached to the postal administration, notably money orders (1817), telegraphs (1878), telephones (1889), and postal checks (1918). Moreover, activities of various kinds have been entrusted to the postal service by other institutions or administrations, such as the National Savings Bank and the National Bank for Old-Age Pensions.

5. India.—From time immemorial the rulers of India maintained their own system of communication between the different parts of the country by means of couriers traveling either on horse or on foot. After the occupation of India by the British, a somewhat similar postal service was established by Robert Clive in 1766, mainly intended for official correspondence. The post was first made available to the public in 1774 when a regular organization was set up, but it was not until 1837 that a monopoly was established in favour of the official post. The post-Independence period (from 1947) was marked by a rapid increase in the number of post offices. By the mid-1960s the number had quadrupled to over 92,000, of which 91% were located in rural areas.

The area to be served is immense, and the cost of transport relatively heavy; moreover, the policy of uniform rates irrespective of distance was accepted as early as 1854 and the aim was to fix the rate as low as possible, the post office never having been expected to make much profit. Separate rates are maintained for parcels, letters, postcards, and newspapers, and there is an old-established C.O.D. service. The volume of mail roughly trebled between 1930 and the mid-1960s, when about nine postal articles were being delivered annually per head of the population. There is a money order service. There is an air parcel service to most other countries. India was the first country in Asia to use airmail (1911) and first-class internal mail is carried by air without surcharge. At the mid-1960s India was one of the few countries to have introduced a uniform rate of postage for airmail postcards and aerograms to destinations abroad.

6. Italy.—In 1862 the Italian government reserved to itself the collection, transport, and delivery of letters, introduced uniform tariffs, and began registration of letters. An express delivery service was introduced in 1890. The first mobile post offices had begun service in 1854; water transport of mail was authorized in 1862 and rail transport in 1865. Mail was first officially carried by air in 1917. There is a post-office monopoly in the trans-

port and delivery of parcels up to 20 kg. weight (1923), but private concerns may be licensed to deal with parcels and they may also collect, transport, and deliver printed matter and newspapers, the government having given up its monopoly in this service in 1873.

Post-office savings banks were started in 1875. Together with the established banks they work on behalf of the deposit and loans bank. Postal orders (for the use of the army only) were first allowed in the kingdom of Sardinia in 1818. This service was extended to civilians in 1849 and throughout united Italy in 1862. Post-office current accounts began in 1917. The post office assists the social services by paying out state pensions, pensions of the National Institute of Social Insurance, and various kinds of grants on behalf of other government departments and relief organizations.

The post office is run by the Ministry of Posts and Telecommunications, the minister being a secretary of state. It is subdivided into central services and offices, provincial directorates (one for each province), and eight regional centres and subcentres.

7. New Zealand.—The first post office was established at Kororareka (now Russell, Bay of Islands) in 1840; by 1858, when the post office was separated from the Customs Department, there were 73 separate offices; and in the mid-1960s they exceeded 1,400. A system of rural mail delivery is operated for more than 70,000 rural boxholders. Penny postage was introduced in 1901, including service with the rest of the Commonwealth and many foreign countries. Airmail services were inaugurated between larger centres of the country in 1936, and between Auckland and Sydney and New Zealand and North America in 1940; the postal air service to London operates via Sydney. Besides available money order and postal note services, the post office has since 1867 provided savings bank facilities. It also acts as agent for such departments as the Inland Revenue Department, the Social Security Department, and the Registrar of Births, Deaths, and Marriages.

8. Pakistan.—An airmail service was set up between the eastern and western parts of the nation soon after the partition of India in 1947. Since then, inland air transport between large towns has been developed, no surcharge being made. Airmail links were also established with Great Britain, the United States, and practically all other foreign countries. The post office concentrates particularly on developing airmail and opening more offices in the villages. A network of helicopter services connects the isolated and otherwise inaccessible localities in the marshy and riverine areas of East Pakistan. (X.)

9. Republic of South Africa.—The first regular postal service was introduced in South Africa in 1803 when communication was established between Cape Town and the important centres by Hottentot postboys. These foot messengers were replaced by horsed post orderlies, and subsequently the development of railways made rapid communication possible on an extensive scale. Later the internal air services provided a means of transmission for letters. The four states of South Africa maintained their separate post offices until the formation of the Union in 1910, when a centralized postal administration was formed.

10. U.S.S.R.—The Soviet post office is one of the oldest in Europe. The creation in the 13th century of the so-called carriage express (postal stations with horses and drivers for the transport of couriers) preceded the organization of a regular system of postal communications. Gradually the carriage express was changed into an organized service for the transmission of written communications. In the second half of the 19th century the building of the railways and the use of steamboats provided a new technical basis for the development of a postal network. By 1913 there were 7,618 communication centres in the Russian empire, but this network was extremely uneven. More than four-fifths of the centres were in European Russia and many centres of population were more than 50 mi. from the nearest post office.

After the Revolution, postal services in the U.S.S.R. developed rapidly. By 1960 the number of postal communication centres had increased eight times in comparison with 1913. More than three-quarters of them were in rural areas, compared with only 3%

in 1913. Between 1913 and the mid-1960s the length of railway postal routes had increased nine times and that of water routes more than five times; the volume of mail carried by train had increased eight times and that by water four times. Beside road transport, express trains, airplanes, and steamboats, use is made of fast launches, hydrofoils, and airscrew-driven sledges. A semi-automatic letter-sorting machine is being mass-produced and machines have been developed for coding, tying of parcels, gluing of labels, stowage of packages in bags, sorting of parcels, and conveying of objects inside large post offices.

IV. INTERNATIONAL POSTAL SERVICE

1. Early History.—The importance of the international mail service is evident from the earliest days of post-office history, but the working of the service is somewhat obscure. In the 16th century a regular service seems to have been provided between London and Calais, France. In 1670, a regular postal treaty was concluded between England and France. This was renewed in 1698 after the conclusion of the Treaty of Rijswijk. The postal treaty provided that the mail being sent from London to Paris and from Paris to London was to leave twice a week. Between Dover and Calais the English post office provided the mail packets in both directions; the service beyond Calais was provided by France. Letters could be prepaid to only three destinations—Paris, Rouen, or Lyons; any charges for further transmission were collected from the addressee. This treaty, soon interrupted by further hostilities, was again renewed in 1713. The new version contained the germ of the international system of accounting for transit mails which lasted with but slight alteration until the latter part of the 19th century. On letters for Italy, which could be franked to Turin, England was to pay France at the rate of 21 sols per single letter; on letters for Spain franked to Bayonne the payment was 19 sols; on letters for Turkey franked to Marseilles, 17 sols. The accounting between the two offices was based on the sum of the amounts due on the separate letters, mail by mail. The principles adopted in the 17th century showed little change in the 18th, and a treaty concluded with France in 1802 showed comparatively little variation from its predecessors of more than a century before.

As time went on the postal treaties required for the establishment of a gradually expanding foreign service became more and more numerous and complicated. The postage depended on the sums payable to the various post offices concerned in the transit of the letters, and these were often based on their own internal rates and units of weight. The result was an extraordinary variety of rates. Prepayment was in some cases compulsory, in some cases optional; but compulsory prepayment covered conveyance only up to a certain point, all charges beyond that point being collected from the addressee. In 1856 the lowest postage in force was that between England and France, which was 4d. per $\frac{1}{2}$ oz. A letter from England to Belgrade, Yugos., via France, weighing over three-quarters of an ounce and up to one ounce, cost 4s. 4d.; a half-ounce letter to California via Panama cost 2s. 4d., in addition to a further charge on delivery. Even to Spain the postage was 2s. 2d. per $\frac{1}{2}$ oz., plus a charge on delivery.

From the point of view of post-office management, the industrial development of the 19th century and the constant growth of correspondence caused the service to become so complex that rapid and accurate handling of the mails was practicably impossible. Almost the only advance made over 17th-century procedure was that letters were weighed in bulk instead of singly. The example of a simple and uniform tariff had been set by the establishment of internal penny postage, but the principle which underlay this (viz., that the cost of conveyance of a letter represented only a small fraction of the total cost of its treatment) was far from being applicable to the conditions of the international post.

2. Formation of the Universal Postal Union.—The first step in the direction of reform was taken by the United States, which in 1862 suggested a conference for the purpose of considering the improvement and simplification of international postal relations. The conference met in Paris in 1863 and adopted a code of 31 articles, intended to serve as the basis of international con-

ventions. Further progress was delayed first by the American Civil War and then by the Franco-German War.

In the meantime, however, another great postal reformer, Heinrich von Stephan of the North German Postal Confederation, had prepared a plan for a universal postal union, based in part on the conclusions of the conference and in part on the experience of Germany, which several years before had formed a postal union including Prussia, Austria, and all the other German states, nearly 20 in number. The Swiss government, at the instance of Germany, summoned a conference to meet at Bern to consider the proposal to form a general postal union.

The Congress of Bern in 1874 was attended by the representatives of 22 countries, including all the countries of Europe plus the United States and Egypt. The result was the signature of the first International Postal Convention, which created the General Union of Posts. Membership increased rapidly and in 1878 the name was changed to the Universal Postal Union. Ten years after its foundation the Union included 55 member countries and by the middle of the 19th century nearly all parts of the world were included. In the early 1960s the Union had more than 100 members.

3. Principles of the Union.—The international convention, which from 1875, with comparatively little modification, remained the foundation of the international postal service, set forth five main principles. The first and fundamental principle was contained in a striking article which stated that for the purposes of postal communication all the signatory countries formed a single territory. The practical application of this principle lies in the doctrine of liberty of transit; every member of the union binds itself to transmit the mails entrusted to it by every other member by the best means of communication which it employs for its own mail. Thus each country has in effect the full and unrestricted use of the transportation services of the whole world, and any improvement made by any member of the Union is placed at the disposal of any other which desires to utilize it.

The second principle was the uniformity of postage rates and of units of weight. The Congress of Bern adopted the rate of 25 gold centimes per 15 grams for letters, but permitted a certain variation within a definite maximum and minimum, and the rate of 7 gold centimes, with a similar variation, per 50 grams of printed papers. In 1878, however, standard uniform rates in gold centimes were adopted for letters, postcards, and printed papers; these rates were retained unaltered until 1920. The only variation allowed was the addition of a surtax when heavy costs for sea transport were incurred. The conditions following World War I swept away the uniformity which had prevailed for 40 years and brought about a reversion to the original principle of a maximum and a minimum rate; this has been maintained ever since. The only change in the units of weight has been the raising of the letter unit from 15 to 20 g., or to one ounce for English-speaking countries.

The third principle was the classification of postal correspondence into three groups—letters, postcards, and other matter (including printed papers, commercial papers, and samples). Definite conditions of acceptance, as well as separate rates of postage, were adopted; the delicate distinctions between what can be sent at the cheap rate and what must be charged as a letter depend on international decisions binding on individual countries.

The fourth principle was the adoption of definite payments to be made by the country which dispatched mails by the train or steamships of another country for the use of those services. The only exception to this principle is that no payment is made to the country of destination, the flow of correspondence in each direction being assumed to be approximately equal.

The fifth principle was the universal adoption of a system of registration and compensation. International registration differs from internal registration in one important particular: the compensation payable is a fixed amount and is allowed only in the event of the entire loss of the registered packet and not for damage to or loss of contents. This principle the union has steadily maintained from its inception.

4. Later Changes.—The original convention applied only to

letter mails, but supplementary agreements were soon adopted at successive congresses for various extensions of the postal service. In 1878 an agreement for an international money order service was signed by a considerable number of countries. At the same time an insurance service, which provided for payment of compensation for loss or damage of letters containing documents of value (paper, money, etc.), was established. This was later extended to cover insured boxes containing valuables such as gold or jewelry. The amount insured varies with the fee paid, and the maximum varies in different countries.

A further important advance was made in 1880 when 19 countries concluded a parcel post agreement. The original agreement was limited to parcels not exceeding three kilograms; it prescribed a simple procedure and fixed rates of payment for both terminal and transit countries. The scope of the service expanded considerably and provided for insurance and cash on delivery. These supplementary agreements were not adopted universally throughout the Union, but, where separate agreements had to be concluded, they generally followed with only slight variations the principles sanctioned by the Union. In 1947 the Union became a specialized agency of the United Nations.

5. The Postal Union Organization.—Most questions are settled between the countries immediately concerned, serious disputes being dealt with by a system of compulsory arbitration. For matters in which the whole Union is concerned, however, an International Bureau is maintained at Bern, Switz. This serves as a centre of information and consultation and, if required, as a clearinghouse in the settlement of accounts. It is the only permanent organ of the Union and acts as a general secretariat for the higher organs. A congress meets, usually every five years, to review the Universal Postal Convention and the subordinate agreements, every member being invited to send delegates. A 20-member Executive and Liaison Committee meets annually in Switzerland to maintain contact with the United Nations and other international organizations, supervise the International Bureau and appoint the higher officials of the Bureau. A consultative committee for postal studies, also having 20 members, was created in 1957 to undertake a more thorough study of economic, technical, and operational problems in the postal service.

6. Commonwealth Preferential Postage.—The idea of adopting preferential postage rates on political grounds began to develop in the era following the establishment of the Universal Postal Union, and it was decided in 1897 that the postal union convention should permit the establishment, by agreement, of rates below the standard postage. This decision, coinciding with a growth of the feeling of the unity of the Commonwealth of Nations, led to the introduction by the United Kingdom in 1899, following a special conference, of "imperial penny postage" at a rate of 1d. per ½ oz. to Canada, India, South Africa, and the crown colonies generally; it was extended to New Zealand in 1901 and Australia in 1905. Certain foreign countries, including the United States, which were closely linked with the United Kingdom by tradition or trade, were subsequently included in the scheme, but the preferential rate to these countries was withdrawn in 1957 for financial reasons. Throughout the various changes in letter postage brought about by World Wars I and II the principle of maintaining the initial Commonwealth letter rate at the same point as the initial inland rate has been uniformly observed.

POSTCARD, a card for transmitting a message that can be mailed without an envelope. The first government-issued cards were the straw-coloured Austrian *Korrespondenz Karte* (with a two-kreuzer stamp) issued in October 1869.

In the United States John P. Charlton of Philadelphia in 1861 obtained a copyright for privately printed cards decorated with a border pattern; the copyright later passed to his fellow townsman, M. L. Lipman. The U.S. government issued postal cards with imprinted stamps in May 1873. Until 1898 privately printed souvenir cards required a two-cent stamp (double the amount of the government card) if they bore a message.

Germany, Switzerland, and Great Britain followed Austria's example in supplying postcards through the post offices. The British buff and violet cards, imprinted with the halfpenny stamp, were issued in October 1870 and sold 76,000,000 in the first year.

Various claims to the invention of the picture postcard have been made. The best known is perhaps that of Léon Besnardeau of Sillé-le-Guillaume, near Le Mans, France, who devised a card for Breton soldiers during the Franco-German War. These postcards bore an engraving of the battlefield, with stacked arms, around a space for the address.

Postcards bearing small engraved views appeared in the 1870s in Germany and Austria, but in Great Britain their publication was not possible until 1894, when the post office relinquished the right to charge the letter rate on any card other than the official one. Designers were hampered by the rule forbidding correspondence on the side that carried the address. This rule was waived in Britain in 1897, in France in 1903, in Germany in 1905, and in the U.S. in 1907.

Artists who designed postcards at the beginning of the 20th century included Alphonse Mucha, Phil May (q.v.), and Louis Wain. Photomontage (superimposition of photographs) and the combination of drawing and photography were introduced for postcards. At first coloured by hand, colour printing of photographs was adopted by Edwin Bamforth, whose "song and hymn" cards became very popular during World War I.

Collecting picture postcards was an immensely popular hobby in the first decade of the 20th century. Societies and journals dealing with postcards existed in most countries, while a number of societies continued in the U.S. in the second half of the century. The postcard remains an important item of stationery trade.

POSTER. A poster is an announcement publicly exhibited which is designed to be understood at a glance. Advertising an event, product or service, the poster must combine immediate visual effectiveness with concise communication of a message; it must compete for attention in visually confusing surroundings and yet inform the spectator or communicate the advertiser's message to him. The design of posters is a challenge to the artist, and besides their value as commercial objects many posters are of aesthetic interest. Some noted artists have designed posters, and their work has been studied and collected by students of the arts.

History and Development.—A kind of advertising closely related to the poster is the signboard or shop sign, hand painted on a wall or on a piece of wood. Signboards of this kind are still used widely, and they have been present in cities and towns through the ages. In their use of a striking symbol rendered in bold shapes and colours, with wording kept to a minimum, these signs are undoubtedly among the ancestors of the modern poster. But in modern times most posters are printed, and identical copies are posted in many different locations joining familiarity with visual impact in the advertising campaign for which the poster is used.

Printing (q.v.), as it now exists, dates from the middle of the 15th century. The first posters which have been preserved date from the early years of printing. Composed almost entirely of

If it plese any man spiritual or temporel to bye any
pyes of two and thre comemoracions of saluburn vs
enprynted after the forme of this prelat letter whiche
ben wel and truly correct late hym come to westmo/
nester in to the almonestye at the red pale and he shal
haue them good chepe . . .

* Pray, do not pull down the Advertisement.

BY COURTESY OF THE JOHN RYLANDS LIBRARY, MANCHESTER

CAXTON'S ADVERTISEMENT, PRINTED 1477, THE EARLIEST PRINTER'S ADVERTISEMENT IN ENGLISH

The handwriting ("Pray, do not pull down the Advertisement"), a later addition, translates the statement in Latin at the end of the notice

text, these posters carried notices of royal proclamations, tax assessments, fairs, markets and newly printed books. From a note on the bottom of one such poster (issued by an English printer and bookseller) it is known that these were meant to be left posted in public places, and hence they were an economical means of carrying a message to great numbers of persons.

Illustrations appear on posters from the early period of printmaking. Handbills often illustrated with crude but spirited woodcuts were used as broadsides which recounted notable happenings; these were essentially newssheets in poster form. The widespread use of posters to advertise products for sale (other than books) does not seem to occur before the early years of the 19th century.

Beginnings of the Modern Poster.—In the 19th century the expansion of industry gave new impetus to poster advertising. Now wealthy patronage was available, and there had also been devised a new method of printing—lithography (*q.v.*)—which allowed brilliantly coloured posters to be produced cheaply and easily. Since the process allows the image to be drawn directly onto the printing surface, and does not physically alter the drawing in preparing it for printing, artists soon saw in lithography a medium which allowed them to design posters freely and simply. The firm of Rouchon in Paris was one of the pioneers in poster printing, and boldly coloured lithographic posters issued from it as early as 1845. Among the earliest French artists whose work was utilized for posters are Paul Baudry and Denis Auguste Raffet.

But it was not until 1867 that the first of the great modern poster artists began his career. Jules Chéret left Paris as a young man, in 1856, to study colour lithography in London. When he returned ten years later, he immediately became interested in the problem of designing theatrical posters. In 1867 Chéret's first poster was published, announcing the appearance of Sarah Bernhardt in the play *La Biche au Bois*. Chéret's style immediately attracted great interest; he used clear, rather pastel colours and shimmering, vignettéd backgrounds, against which he placed delicate and elegant figures. His lettering was bold and gaily coloured, and the whole effect of his posters is extremely arresting. The visual impact of Chéret's work, coupled with the fact that he was a prolific worker (he designed about 1,000 posters) make his designs a major influence on later 19th-century posters. But there were other developments as well. During the last quarter of the 19th century there was an expansion of the realm of the fine arts. Artists no longer felt constrained to work only in painting or sculpture, but turned as well to designing furnishings, books, textiles and other useful things. Posters were not neglected. Painters such as Edouard Manet, Pierre Bonnard, Edouard Vuillard, and Henri de Toulouse-Lautrec all worked in the field, and the last-named is one of the great masters of the medium.

Toulouse-Lautrec was a master of trenchant characterization, and the means he used in his posters were bold and simple. Inspired by the work of Manet and Edgar Degas, as well as by Japanese colour woodcuts, Toulouse-Lautrec rendered his designs in large, interestingly shaped areas of bold colour and simple values. He used an exceedingly restricted range of colours and textures, carefully combining his shapes with line for maximum

visual effectiveness. His line was bold, but sinuous and sensitive, and his backgrounds were the utmost in simplicity—often consisting of the blank paper itself carefully worked into the design of the whole poster. The lettering of Toulouse-Lautrec's posters was kept to a minimum, and the style of letter he used picked up curving rhythms and colours from the illustrations, welding the entire poster into a unified design. He produced his first poster in 1891, after more than ten years' work at painting and drawing. Between 1891 and 1899 he produced about 30 posters—among them several for clients in England and in the United States.

A contemporary of Toulouse-Lautrec whose work is closely related in style is T. A. Steinlen. The two men worked for some of the same clients, and in fact Steinlen's style seems to have been one of the influences upon Toulouse-Lautrec's early posters. The boldness of their work made Toulouse-Lautrec and Steinlen pioneers of a new movement in poster design, and their influence was felt in every European country and in the United States during the 1890s.

The imprint of these French artists can be found in the work of Edward Penfield and Will Bradley in the U.S. The posters of the "Beggars Brothers" (William Nicholson and James Pryde) in England carry boldness and simplicity even further. Another English artist, Aubrey Beardsley, designed a few posters which had an impact comparable to Toulouse-Lautrec's. Beardsley's elegantly curved thin line, equally elegant solid shapes, and his elaborate linear and dotted textures, created a mood of luxurious and almost mysterious sensuousness. Around 1900 many young artists found this attractive, and Beardsley must join Toulouse-Lautrec as one of the main sources in poster and illustrative art for the so-called *art nouveau* (*q.v.*). England and the U.S. had begun to produce illustrated posters in the 1870s, and with the addition of a style of illustration deriving from the popular painting of the time (*i.e.*, the adaptation of Sir John E. Millais' "Bubbles" into a soap poster in England), the posters designed in these countries generally followed French developments. Artists in other European countries produced work along similar lines.

20th-Century Posters.—Around 1900 several new movements in art were forming in the Netherlands, in Germany and in Austria. In the field of poster design, France had previously been a leader, but now for the first time its supremacy as a source for innovation was challenged. Developing further some of the ideas first enunciated by John Ruskin and William Morris, these artists showed an interest in crafts, techniques and in machine-made forms; this interest motivated them to make use of simple colour schemes based on primary colours, geometrically derived patterns, etc. Their efforts culminated in the work of the Bauhaus at Weimar and Dessau (1919–28) in Germany. The Bauhaus was an

art school, and the work of both professors and students gave a new direction to design in posters and in every other field. Although its posters were actually of little significance in themselves, and despite the fact that its more radical innovations were subsequently abandoned, the Bauhaus (*q.v.*) remained the major influence through the mid-20th century.

Artists such as Herbert Bayer, Josef Albers, Gyorgy Kepes and later E. McKnight Kauffer organized lettering and pictorial matter into clearly defined rectangular and curved areas. Elaboration of colour and of letter forms was kept to a minimum, and some designers even gave up the use of mixed upper- and lower-case letters to avoid distracting variations in size and shape.

With the growth of the advertising industry in the 20th century, the poster assumed greater importance than ever. Cassandre, Carlu and Savignac were typical of the better French poster designers of the generation following World War I; their work combined simplicity and visual force with genuine wit, and the fame of their posters became world-wide. During World Wars I and II, the major powers involved paid tribute to the effectiveness of the poster in according it many tasks; armed forces were recruited, bond issues advertised, participation in the war effort maintained, all by use of large-scale poster campaigns. James Montgomery Flagg and Ben Shahn were typical of the artists who designed posters for the United States in World Wars I and II, respectively.

Another widespread use of posters is to advertise the services of transportation companies. A pioneer in this field was the London Transport company in England, which began in 1908 not only to advertise its services but also to commission prominent and promising artists to design posters describing places which could be reached using the facilities of London Transport. Undoubtedly the entire travel-poster industry owes much to the initiative of the directors of London Transport. By the 1930s virtually every major transportation company was publishing and distributing posters. With the increase in the use of posters in the 20th century, it became necessary to institute measures for the control and limitation of public advertising. Laws to control the dimensions and placement of hanging signs were instituted as early as the 18th century both in England and in France, and similar regulations exist in modern times in many countries the world over. In the 20th century city governmental authority has been exercised to limit the placement of posters on walls, and there exist standardizing and limiting measures to govern the use of free-standing billboards. See also ADVERTISING.

POST HORN, a brass musical instrument of cylindrical bore, formerly used by guards of mail coaches. At the end of the 18th century post horns were crescent-shaped, coiled, or straight. The notes sounded were at most six (harmonics 2 to 7; see HORN). The coach horn, like a straight post horn though longer, was made of copper instead of brass and was of conical bore. It was in use on the London-Oxford mail coach until 1914.

POSTIMPRESSIONISM is a collective designation for isolated trends that arose in late 19th-century French painting out of dissatisfaction with the formlessness and limited aims of Impressionism (*q.v.*). In no sense a movement, it is summed up in the individual researches of Cézanne, Seurat, Van Gogh, and Gauguin, whose achievements, if undervalued in their own time, became signposts for the main directions of the modern movement.

After a phase of uneasy dissension among the Impressionists, Paul Cézanne (*q.v.*) withdrew from the movement in 1878, in order "to make of Impressionism something solid and durable like the art of the museums." In 1884, at the Salon des Artistes Indépendants, Georges Seurat (*q.v.*) revealed a like intention with his picture "Une Baignade-Asnières." Cézanne studied indefati-

gably to present nature in terms of advancing and receding planes (see also CUBISM). Seurat's investigations into the science of colour and into aesthetic theories led him to develop the Pointillist technique, his unerring sense of relationships between tones, intervals and accents reinforcing his Impressionist subject matter with a secure scaffolding and a harmonious unity.

Cézanne worked in isolation at Aix; his solitude was matched by that of Paul Gauguin (*q.v.*) in the Pacific and of Vincent Van Gogh (*q.v.*) at Arles. Gauguin, after he had exhibited at the eighth and final group show of the Impressionists in 1886, renounced "the abominable error of naturalism" and began to paint imaginative concepts, as distinct from imitations, of form. He set out for the South Seas where his search for simplicity culminated in a richly coloured and decorative symbolism. Van Gogh arrived in Paris in 1886 and was attracted to Impressionist colour and the Pointillist technique. In his few remaining years, he made use of these influences, not as techniques of recording, but as means of expressing his acutely felt emotions. POSTLIMINY. Postliminy is a technical term that international lawyers apply to the status of a government in its own territory when this territory has been reacquired from an invading enemy. The territory reacquired may have been the whole territory of the invaded country or merely a part.

Originally the term postliminy was applied to a different situation. A Roman citizen lost all his civil property and matrimonial rights if he became the prisoner of war of an enemy. If he returned he was automatically restored to all his previous rights and obligations and that restoration was called postliminy.

Some few writers still use the term postliminy in the old Roman sense, and a few apply the term to other postwar restoration problems. An example of the latter would be the return of German assets sequestered in the United States during World War II. (See ALIEN PROPERTY.)

Postliminy in its chief meaning, which applies to returning sovereigns, operates immediately, long before the peace treaty. Normally in the international law of war all final settlements are postponed until peace treaties are made. Under postliminy, however, the returning sovereign may act immediately as if its government had never been absent. Public property seized by the enemy is immediately reacquired. Enemy legislation may be canceled, even with retroactive effect. Property which the enemy has seized and sold may be restored to the owner. Traitors and collaborationists may be punished.

The logical implications of postliminy are so extreme that other rules of international law and morality have to operate against extreme abuses. For instance it would be going too far under postliminy to annul all criminal sentences, to carry actions against collaborationists to the point of imposing standards of martyrdom on the population or to collect debts and taxes already collected by the enemy.

POST-MORTEM EXAMINATION: see AUTOPSY.

POSTOJNA (Italian POSTUMIA, German ADELBERG), a town in western Slovenia, Yugos., lies in a karst field on the Pivka River, 32 mi. (52 km.) NE of Trieste by road. Pop. (1961) 4,848. It is on the railway and road from Trieste to Ljubljana and on the road to Rijeka. It has several schools, a theatre, and the Institute of the Slovene Academy of Science. The town is overlooked by a medieval fortress on Sovic Hill. It developed as a marketplace under the protection of the fortress. In the 12th and 13th centuries it belonged to the patriarch of Aquileia; later it fell under Habsburg rule. Italy occupied it in 1918 and Yugoslavia in 1947.

A mile from the town is the entrance to the vast stalactite cavern of Postojna, which is divided into several branches. The Pivka River enters the cavern 60 ft. (18 m.) below its mouth, runs underground, and reappears at Polje Planine. The cavern has 16 mi. (26 km.) of corridors and grottoes containing many stalactite and stalagmite formations. Notable are "the Concert Hall," "the Ballroom," and "Paradise Grotto." These subterranean wonders were known as early as 1213 (the earliest inscribed names date from 1250) and were probably visited by Dante, who certainly knew the lake of Cerkničko Jezero in which the Javornik Mountain is reflected. But the cavern was unknown in modern times until 1818. In a part of the cavern is found the remarkable subterranean amphibian *Proteus anguinus*, which can reach a foot in length, lives on snails and worms, and has both lungs and gills. In 1872 a railway (now electrified) was built through the cavern for tourists. Electricity was introduced in 1884. (V. DE.)

POSTULATE, a proposition assumed without proof in founding a mathematical discipline. Though the propositions of a particular mathematical discipline, or branch of mathematics, are generally established by proof, there must be some unproved first principles, if the process of basing one proposition on others from which it is proved is not to be an infinite regress. Similarly, although the terms used are generally introduced by definition, there must be some undefined terms. These unproved first principles are the *postulates*, and the terms not defined are the *primitive terms*. (See AXIOM; LOGIC; HISTORY OF.)

For example, in the case of Peano's postulates for arithmetic (so called after Giuseppe Peano, who proposed them as first principles of arithmetic, though the postulates themselves are due rather to C. S. Peirce and Richard Dedekind), the primitive terms are "0," "number" (in the sense of non-negative whole number) and "successor" (in the sense that $x + 1$ is the successor of x). And the postulates themselves are: (1) 0 is a number. (2) Every number has a number as its unique successor. (3) Two numbers having the same successor are identical. (4) 0 is not successor of any number. (5) If 0 belongs to a class F , and if whenever a number x belongs to F the successor of x belongs also to F , then all numbers belong to F .

These may be expressed in logistic notation (see LOGIC) by using an individual constant 0, and two functional constants N and S (" $N(x)$ " to mean " x is a number," and " $S(x, y)$ " to mean " y is successor of x "). However, the implicit assumption that it is only numbers that have successors is best represented by defining $N(x)$ to stand for $(\exists y)S(x, y)$ (and $N(y)$ to stand for $(\exists x)S(x, y)$, etc.), so that the number of primitive terms is reduced to two. The statement of some of the postulates may then be simplified, and the second postulate is also conveniently divided into two parts: (1) $N(0)$. (2) $S(x, y) \supset N(y)$. (2) $S(x, y) \supset S(x, z) \supset y = z$. (3) $S(y, x) \supset S(x, x) \supset y = x$. (4) $\sim S(x, 0)$. (5) $F(0) \supset F(x)S(x, y) \supset F(y) \supset N(x) \supset F(x)$. The postulates have to be added to an underlying logic, which in this case must be a functional calculus of at least second order (see LOGIC) to make definitions possible of addition and multiplication of numbers.

Another familiar example of mathematical postulates is that of the postulates for elementary geometry. As in other cases, the postulates for a particular discipline are not uniquely determined, and various alternative systems of postulates are known. The original axioms and postulates of Euclid are the prototype of axiomatic treatments of geometry, and are in a certain sense still standard, though they do not satisfy modern requirements of rigour. For modern systems of postulates for geometry see the works of Hilbert and of Veblen, cited in the bibliography below.

According to the view now usual, the postulates constitute a definition of the particular mathematical discipline; and a change of one of the postulates to something different or contrary would not be wrong, but would merely lead to the definition of a different discipline. This contrasts with an older view according to which the postulates of arithmetic or of Euclidean geometry are a priori truths. The abandonment of the older view was brought about largely by the discovery of non-Euclidean geometry (see GEOMETRY, NON-EUCLIDEAN; MATHEMATICS, FOUN-

DATIONS OF), since Euclid's parallel postulate and its contradictory lead to two geometries which not only are equally sound logically but, in the absence of experimental evidence against the Euclidean postulate, would be equally applicable to physical space.

A set of postulates is called *consistent* if, in the mathematical discipline which the postulates determine, not both A and $\sim A$ are ever theorems. A particular postulate is *independent* if it is not a theorem of the discipline determined by the remaining postulates.

In general, a mathematical discipline based on a consistent set of postulates can be strengthened (without adding to the list of primitive terms) by adding new, independent postulates in various alternative ways. But if the set of postulates is *categorical* there is a sense in which this is not possible. (See CATEGORICAL.)

Use of axioms and postulates for a rigorous account of the foundations of a branch of natural science is less usual than in mathematics, and its appropriateness is still the subject of controversy. Some reject the postulational form for theoretical science altogether. And some regard it as an ideal to which the development of a science approaches, not yet attained except in the case of applied geometry and possibly mechanics, and not a useful form in at least the present stage of most sciences. But a noteworthy attempt to apply the axiomatic method in biology is contained in the writings of J. H. Woodger, whose book (cited below) may be consulted both for this and for an expository account of the axiomatic or postulational method in general.

Veblen, "A System of Axioms for Geometry," *Trans. Amer. Math. Soc.*, vol. 5, pp. 343-384 (1904); J. H. Woodger, *The Axiomatic Method in Biology* (1937). (A.O.C.)

POSTUMUS (MARCUS CASSIANUS LATINUS POSTUMUS), rival Roman emperor A.D. c. 258-268 in Gaul. When Gallienus left the Rhine for the Danube about 258, he left his son Saloninus in Cologne with the generals Silvanus and Postumus. When Postumus distributed booty recovered from the enemy to his troops, Silvanus demanded that it be handed back to the treasury and its original owners. The reluctant troops proclaimed Postumus emperor, and defeated and killed Saloninus and Silvanus. Postumus successfully defended the Rhine frontier, and withstood Gallienus' somewhat ineffective attempts to recover Gaul. In his last years he took his successor Victorinus as colleague, certainly as consul, perhaps as joint emperor, but was killed in a mutiny of the legion of Mogontiacum (Mainz) instigated by Laelian (q.v.). (J.N.R.M.)

POTASH, the crude potassium carbonate obtained by lixiviating wood ashes and evaporating the solution to dryness, an operation at one time carried out in iron pots—hence the name from "pot" and "ash." The term "potash" or "caustic potash" is frequently used for potassium hydroxide. In fertilizer terminology, potassium oxide (K_2O) is called potash. See POTASSIUM.

POTASSIUM, a silvery white metal with a brilliant lustre is one of the most reactive of the metallic elements. This property is illustrated when it is dropped into water; hydrogen is displaced and both the hydrogen and the potassium take fire, burning with a violet flame that usually culminates in a slight explosion.

Potassium is not found in a free state in nature, but in combined form is distributed in nearly all soils and terrestrial waters, and many rocks. It is important for the nutrition of plants, and its compounds are contained in most plant and animal tissues.

Potassium chloride is an important fertilizer. Other potassium compounds have a wide range of industrial and pharmaceutical applications. Metallic potassium has few uses, the most important being the preparation of potassium superoxide (KO_2) for the manufacture of protective breathing equipment. In the rebreather gas mask, the KO_2 reacts with the exhaled air to liberate oxygen and remove carbon dioxide and water.

The symbol of potassium is K (from kalium, a Latinized form of the Arabic word for alkali). Its atomic number is 19, chemical atomic weight 39.102.

Historical Background.—The history of potassium is closely linked to that of sodium. Materials containing their compounds, particularly carbonates and nitrates, were known and used in some

of the earliest civilizations. Native sodium carbonate was used by the Egyptians for making glass as early as the 16th century B.C.; records originating in lower Mesopotamia and dating from the 17th century B.C. mention the use of saltpetre for making glazes. However, the ancient technicians and artisans who used these materials, having no knowledge of the chemical and physical methods of analysis and identification, did not distinguish between similar sodium and potassium compounds. The terms used were often general and implied the source rather than the chemical content of the material. Alkali (*q.v.*) originally referred only to the material obtained from the ashes of plants, sodium and potassium carbonates. The term soda (*q.v.*), of unknown etymology, was first applied to any alkali and later to the ash of sea plants, while the term potash (pot-ash) was applied to the ash of land vegetations, both of which generally contained a greater proportion of potassium carbonate. The two alkalies, soda and potash, were successively designated as natural and artificial and as mineral and vegetable. In the first decade of the 15th century, potassium salts were being produced in Scotland from the ashes of seaweed. Finally in the 18th century, after it was shown that the "mineral alkali" occurred in the ashes of sea plants and the "vegetable alkali" in a number of minerals, the terms soda and potash were properly applied to specific substances. Since the chemical nature of these common alkalies had not yet been determined, they were believed by some to be elements. A. Lavoisier did not include them in his list of elements, "because," he stated, "these substances are evidently compounds, although however, the nature of the principles which enter into their composition is still unknown." This problem was finally solved in 1807 by the brilliant young English chemist Sir Humphry Davy, who decomposed both the alkalies, obtaining the metals potassium and sodium. It was he who coined the word "potassium"—a Latinized version of "potash."

Since potassium is one of the strongest reducing agents known, it cannot be isolated by chemical reduction without resorting to unusual conditions which favour the necessary equilibrium shift and permit the removal of the product from the system as it is formed. It is therefore not surprising that potassium and the other alkali metals were prepared only after the discovery of current electricity (1800) and the subsequent development of electrolytic methods. Davy prepared potassium by the electrolysis of molten potassium hydroxide using platinum electrodes. He described the experiment:

A small piece of pure potash . . . was placed upon an insulated disc of platina, connected with the negative side of the battery . . . ; and a platina wire, communicating with the positive side, was brought in contact with the upper surface of the alkali. . . . The potash began to fuse at both its points of electrization. There was a violent effervescence at the upper surface; at the lower or negative surface, there was no liberation of elastic fluid, but small globules having a high metallic lustre . . . appeared, some of which burnt with explosion and bright flame, as soon as they were formed, and others remained, and were merely tarnished, and finally covered with a white film which formed on their surfaces. These globules, numerous experiments soon showed to be the substance I was in search of and a peculiar inflammable principle the basis of potash.

Occurrence and Production.—It is estimated that potassium constitutes about 2.59% of the igneous rocks of the earth's crust, ranking seventh in order of abundance of elements. Its compounds are widely distributed in the primary rocks, the oceans, the soil, plants and animals. Although nearly as abundant as sodium, it is less accessible, and relatively few workable mineral deposits are available; these contain saline residues formed by the evaporation of inland seas which existed in past geological eras. The principal deposit, at Stassfurt, Ger., contains the following minerals: carnallite, $\text{KCl} \cdot \text{MgCl}_2 \cdot 6\text{H}_2\text{O}$; kieserite, $\text{MgSO}_4 \cdot \text{H}_2\text{O}$; polyhalite, $\text{K}_2\text{SO}_4 \cdot \text{MgSO}_4 \cdot 2\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$; as well as kainite, $\text{MgSO}_4 \cdot \text{KCl} \cdot 3\text{H}_2\text{O}$. Important deposits at Wittelsheim in Alsace and in eastern Galicia, Spain, contain sylvinites, $\text{KCl} \cdot \text{NaCl}$. One near Kalusz in the Ukrainian S.S.R. contains sylvite, KCl ; langbeinite, $\text{K}_2\text{SO}_4 \cdot 2\text{MgSO}_4$; and kainite. Additional saline deposits are at Carlsbad, N.M., Cardona, Sp., Searles lake in California, the Dead sea in Palestine, Tunis, Lake Elton in the Urals, and Chile. The above minerals are soluble in water and conse-

quently are easily extracted and readily amenable to chemical operations. They represent, however, only a very small fraction of the total quantity of potassium in the earth's crust, the great bulk of which is found in the igneous rocks.

Potassium occurs as an alkali constituent in a number of aluminosilicate minerals, examples of which are: leucite, $\text{KAl}(\text{SiO}_3)_2$; muscovite mica, $\text{KAl}_3\text{Si}_3\text{O}_{10}(\text{OH})_2$; orthoclase feldspar, KAlSi_3O_8 ; and biotite, $\text{KHMg}_2\text{Al}_2(\text{SiO}_4)_3$. These and other silicate minerals are insoluble in water and, with the exception of leucite, are not processed for their potassium content. In the weathering of igneous rocks, feldspar, for example, is decomposed into clay and soluble potassium salts; it might be expected that the latter would be ultimately carried to the sea by the surface waters. However, the potassium salts are retained by the soil to a large extent, more so than those of sodium, and are utilized by plants. The retention of the potassium ions by the soil may be a result in part of an ion exchange between potassium and the sodium salt of a complex sodium aluminum silicate which belongs to a class of compounds known as zeolites; *e.g.*,

Soluble potassium salts which are present in all fertile soils are drawn into the roots of plants and accumulate in the plant structure. In the process of plant metabolism part of the inorganic potassium salts are converted into potassium salts of organic acids (*e.g.*, tartrates and oxalates), which, when the plants are burned, are in turn converted to potassium carbonate. All plant structures are therefore potential sources of potassium compounds. The proportion of potassium present in the total plant or animal organism varies widely, but in most vegetation and in higher animals the potassium content is greater than that of sodium. In sea vegetation the balance is more in favour of sodium, but the potassium content is high and in some seaweeds is in excess of that of sodium. Sugar cane and sugar beets contain significant quantities of potassium salts, but the bulk of it (90%) is extracted with the sugar. The residue pulp from the beet or bagasse from the cane therefore contains very little potassium. However, the molasses remaining after the crystallization of the sugar contains 4%–5% of potassium. In some processes the molasses is mixed with the bagasse and burned as a fuel, and the potassium is recovered from the ash. In others the sugar in the molasses is fermented and the potassium salts concentrated in the vinasse, which is the residue liquid from the distillation of the alcohol.

The bulk of the potassium salts of industry is obtained from salt deposits and only a very small fraction (approximately 1%) from plant and animal sources. There remains a vast potential source in the silicate minerals such as leucite, wyomingite and glauconite if economic processes of recovery can be developed.

A number of processes for the preparation of potassium metal by electrolytic reduction and by chemical reduction have been proposed. In 1808 Joseph Gay-Lussac and Louis Thénard obtained the metal by reducing the hydroxide with iron; the materials, including iron wire or turnings, were packed in a gun barrel which was coated with clay and heated to white heat. During the same year F. R. Curadon prepared potassium by a somewhat similar procedure in which he reduced potassium carbonate with carbon:

This reaction was studied by various chemists during the following 50 years, for it was necessary to devise a method for the separation and rapid cooling of the products in order to prevent the formation of the explosive compound $\text{K}_4\text{C}_6\text{O}_8$. These processes were the forerunners of a number of methods in which potassium compounds were reduced by metals such as magnesium and aluminum, or by calcium carbide, hydride or silicide. With the later development of high-vacuum techniques, the use of calcium for reduction of potassium in a vacuum yields the pure metal; the similar use of sodium vapour as the reducing agent has been fairly successful.

Electrolytic methods include the decomposition of the fused hydroxide, the cyanide and a potassium oxy-salt dissolved in a fused

potassium halide. The Castner cell, developed in 1890 for the manufacture of sodium (*q.v.*), was modified for the more difficult potassium operation, but the results were not entirely satisfactory.

There is very little, if any, industrial demand for potassium metal, and no extensive manufacturing process is known to be in operation. During the first half of the 19th century, metallic potassium was used to produce aluminum by the reduction of the chloride; magnesium, boron and silicon were produced by a similar method. It was shown in 1854 that sodium, which can be produced more cheaply, would serve as well as potassium for the production of magnesium and aluminum, and sodium was subsequently used for these purposes until electrolytic processes were developed. Similarly, sodium replaced potassium in other industrial processes in which the latter was used.

Properties.—Naturally occurring potassium consists of three isotopes of mass numbers 39, 40 and 41 with relative abundances 93.1%, 0.0119% and 6.9%, respectively. The least abundant isotope, K^{40} , is radioactive with a half life of 1.2×10^9 years emitting beta particles (electrons):

and, to a lesser extent, gamma radiation by electron capture:

Potassium belongs to the group of alkali metals (Group I of the periodic system) and closely resembles the other elements of the group, lithium, sodium, rubidium, cesium and the short-lived radioactive element francium. The atoms of potassium and the other alkali metals each have a single valence electron which is easily removed whereas the remaining electrons are tightly held by the nucleus in completely filled orbitals. Consequently these elements are the most reactive of all the metals and are the strongest reducing agents known. Their valence or oxidation state is uniformly +1 in all their compounds.

When exposed to air, potassium rapidly tarnishes and becomes coated with a film of oxide or hydroxide. At room temperatures it is soft and pliable and can be cut with a knife, but below 0° C. it is hard and brittle. The vapour of potassium, which is mainly monatomic, contains a small fraction (about 1%) of diatomic molecules which are indicated by a characteristic band spectrum. The solid metal has a body-centred cubic structure with $a = 5.25$ Å. The vapour of potassium is green and it imparts a violet coloration to the flame of a Bunsen burner. The emission spectrum shows a double line (7,699 Å and 7,664 Å) near the infrared and another near the ultraviolet (4,047 Å and 4,044 Å).

Additional physical and atomic properties are listed in Table I.

TABLE I.—Properties of Potassium

Outer electron configuration	$3s^2 3p^6 4s^1$	Heat of hydration of gaseous ions, kg.cal. per mole	77
Density of solid at 20° C., g. per c.c.	0.862	Electronegativity	0.8
Atomic volume of solid, c.c.	45.36	Specific heat at 25° C., cal. per gram	0.177
Melting point, °C.	63.5	Specific electrical resistance at 20° C. ohm-cm.	7×10^{-9}
Boiling point, °C.	757.5	Metallic radius, Å	2.025
Ionization potential, volts	4.34	Ionic radius in crystals, Å	1.33
Potential for $K \rightleftharpoons K^+ + e$	2.925		

Many of the physical and chemical properties of potassium may be correlated with its atomic structure. The difference in the atomic radius and the ionic radius is significant; the volume of the atom is nearly four times as great as that of the ion, the valence electron accounting for nearly three-fourths of the total volume. The potassium atom is the largest of the first 36 elements. The valence electron is therefore at a relatively great distance from the nucleus and is easily lost to other atoms in chemical reactions. In the solid metal the valence electrons hold the atoms together; but there are not enough of them to form stable electron pairs, so the binding of an atom to its neighbours is relatively weak and the valence electrons can easily pass from one ion to another. Accordingly potassium is soft, has a low melting point and is a good conductor of electricity.

The chemistry of potassium is relatively simple; it has a valence of +1, it does not form complex ions and it is joined to other elements or groups of elements in its compounds by ionic bonds.

Potassium is more reactive than sodium and lithium. It inflames spontaneously in moist air, forming a mixture of oxides. Potassium reacts vigorously with water, liberating hydrogen and forming potassium hydroxide. The reaction is:

Potassium reacts with nearly all the electronegative elements, including the halogens, sulfur and phosphorus, forming the corresponding halides, the sulfide and phosphide, respectively; with arsenic and antimony forming K_3As and K_3Sb ; and with hydrogen to form the hydride. It reacts with organic compounds containing reactive groups (alcohols, halides, etc.); e.g.,

and vigorously with acids. When heated gently in the presence of dry ammonia gas, potassium reacts to form the amide:

The amide decomposes into the nitride and ammonia when heated strongly:

Potassium dissolves in liquid ammonia, forming a highly conductive blue solution.

The alloying properties of potassium have not been fully investigated. It does not alloy appreciably with lithium nor with gold, iron, zinc or aluminum, but is mutually soluble with sodium. An alloy containing 22.7% of sodium remains liquid at a minimum temperature of -12.5° C. Potassium reacts vigorously with mercury; a number of compounds of the two elements have been identified, among them KHg_2 . A compound of cadmium, Cd_2K , and one with thallium, KTh , have also been reported.

COMPOUNDS

The compounds of potassium are mostly ionic, and their chemical properties in solution are those of the potassium ion and the respective anions. Practically all the potassium compounds are soluble in water, the exceptions being the perchlorate, $KClO_4$ (slightly soluble); the chloroplatinate, K_2PtCl_6 ; the acid tartrate $KHC_4H_4O_6$; the fluosilicate, K_2SiF_6 ; and the cobaltinitrite $K_3Co(NO_2)_6$. In this and other respects the salts of potassium resemble those of the ammonium ion, NH_4^+ .

Oxides.—Potassium forms three oxides and a fourth of less certain existence has been reported. The monoxide, K_2O , may be prepared by heating the metal in a limited supply of air or by heating the nitrate with potassium:

It is a white solid, yellow at high temperatures, and combines with water to form potassium hydroxide, KOH . The peroxide, K_2O_2 , an orange-coloured solid, is prepared by the reaction of oxygen and the metal, either dry or in liquid ammonia solution. It is not a common substance for it reacts violently with oxygen to form the superoxide. Potassium superoxide, KO_2 , the commonest of the superoxides, first prepared by Gay-Lussac and Thénard, is made by heating the metal in air at 180° – 200° C. or by treating a liquid ammonia solution of the metal with oxygen at -50° C. It is decomposed by water:

and oxidizes carbon monoxide to the dioxide below 100° C. At room temperatures it is an orange-yellow solid which turns black when melted. The melting point is 380° C. and the density is 2.1 g. per cubic centimetre. The compound was for many years formulated as K_2O_4 , but X-ray studies show the potassium ions and superoxide ions, O_2^- , to be arranged in tetragonal structure. It is paramagnetic with a susceptibility corresponding to one unpaired electron spin; thus the simpler formula, KO_2 , is indicated. A trioxide, K_2O_3 , has been reported, but its behaviour suggests that it may be a mixture of the peroxide and the superoxide $K_2O_2 \cdot 2KO_2$.

Potassium hydroxide, or caustic potash, KOH , was formerly

prepared by the reaction of an aqueous solution of potassium carbonate with slaked lime (calcium hydroxide):

The insoluble calcium carbonate was removed by filtration or sedimentation and the hydroxide recovered by evaporation. This was the primitive process whereby the alkali was obtained for soap-making, wood ashes being the source of the carbonate. It was also the standard industrial method until the end of the 19th century, when it was superseded by the electrolytic process. Potassium hydroxide is now manufactured by the electrolysis of an aqueous solution of potassium chloride, whereby chlorine and hydrogen are also produced. The cell used for this electrolysis must be constructed so as to prevent the intermingling of the hydroxide and the chlorine, which react to give the hypochlorite at low temperatures and the chlorate at higher temperatures. The Nelson cell has a graphite anode which is immersed in the salt solution contained in a perforated double-walled steel vessel which serves as a cathode. The vessel is lined with an asbestos diaphragm through which the solution seeps at a rate which prevents the hydroxide, formed at the cathode, from migrating to the anode region. The Castner-Kellner process utilizes a mercury cathode at which the potassium ion is discharged to form an amalgam and the amalgam, in turn, reacts with water to form the hydroxide solution. In either process the chloride and other impurities are removed from the solution containing the hydroxide by crystallization and the hydroxide is recovered by complete evaporation.

Potassium hydroxide is a white solid, stonelike in appearance and brittle with a fibrous crystalline fracture. The density is 2.04 g. per cubic centimetre and it melts at 380° C. It is deliquescent and is sometimes used as a drying agent; if exposed to air, it absorbs water and carbon dioxide. It is very soluble in water; a saturated solution, for example, contains 52.8% of KOH at 20° C. and the solubility increases with the temperature. Solutions of potassium hydroxide are never saturated at the boiling point, which rises steadily with increasing concentration.

Potassium hydroxide is a strong base, being almost totally ionized in dilute solutions. It reacts with the various acids and acid oxides, forming the corresponding salts. As it is more expensive than sodium hydroxide, its use, other than for the manufacture of liquid soaps, is somewhat limited.

Potassium hydride, KH, is prepared by the reaction of hydrogen on the heated metal. It is a white, saltlike compound with a density of 1.43 g. per cubic centimetre and possessing a cubic structure of the sodium chloride type. In the electrolysis of the molten hydrides of this type the hydrogen migrates to the anode, indicating that it is the negative ion. The compound is a strong reducing agent, acting violently on water and liberating hydrogen:

It inflames in air.

Potassium carbonate, K₂CO₃, was formerly obtained almost exclusively by lixiviating plant ashes. The first method used to manufacture this salt on an industrial scale was an adaptation of the Leblanc process, previously developed in France for the production of sodium carbonate. The Solvay process, used to manufacture sodium carbonate, is not applicable to potassium carbonate production because of a difference in the solubility of the two bicarbonates. The crucial reaction in this process takes place because sodium bicarbonate precipitates from a concentrated solution whereas potassium bicarbonate, which is about three times as soluble, does not precipitate under similar conditions.

Potassium carbonate is now made either by the reaction of carbon dioxide on potassium hydroxide,

or by the Engel-Precht process. In the latter process, carbon dioxide is passed into a concentrated solution of potassium chloride containing a suspension of hydrated magnesium carbonate. A double salt of magnesium carbonate and potassium bicarbonate precipitates:

The double salt decomposes when heated:

The magnesium carbonate is removed by filtration and the potassium carbonate crystallized by evaporation of the solution.

The density of potassium carbonate is 2.29 g. per cubic centimetre; the melting point, 881° C.; the solubility in 100 g. of water at 0° C., 105.5 g.; and at 100°, 156 g. Anhydrous potassium carbonate is a white, somewhat deliquescent salt. The hydrate, 2K₂CO₃ · 3H₂O, crystallizes in monoclinic form from a concentrated solution; below -6° C. the hydrate K₂CO₃ · 6H₂O crystallizes.

Although stable toward heat, potassium carbonate is decomposed by steam at red heat temperatures:

When a saturated solution of the carbonate is treated with carbon dioxide, crystals of the less soluble bicarbonate are precipitated:

The normal carbonate of a high degree of purity may be obtained by decomposition of the recrystallized bicarbonate at 190° C.:

Potassium carbonate is used in the manufacture of hard glass, liquid soaps and numerous inorganic chemicals.

Halogen Compounds.—The halides of potassium and of the other alkali metals are typical salts, predominantly ionic and soluble in water. A number of their properties are given in Table II.

TABLE II.—Properties of the Potassium Halides

Property	KF	KCl	KBr	KI
Melting points, °C.	846	768	748	603
Boiling points, °C.	1,498	1,411	1,376	1,330
Densities, g. per c.c.	2.48	1.99	2.75	3.13
Heats of formation, kg. cal. per mole	134.5	104.0	94.2	78.9
Interatomic distances in crystals, Å	2.66	3.14	3.29	3.53

Potassium fluoride, KF, may be prepared by neutralizing potassium carbonate or hydroxide with hydrofluoric acid, and upon evaporation cubic crystals of the salt are obtained. It forms the acid fluoride, KHF₂, when dissolved in hydrofluoric acid solution. Upon heating the acid salt decomposes:

The more complex salts KH₂F₃ and KH₃F₄ have been reported. Potassium fluoride, unlike the other potassium halides, forms hydrates, KF · 2H₂O and KF · 4H₂O.

Potassium chloride, KCl, the most abundant of the naturally occurring potassium salts, closely resembles sodium chloride. It is a constituent of a number of minerals found in the Stassfurt and other deposits, some of which are hydrated double salts; e.g., kainite, MgSO₄ · KCl · 3H₂O. Potassium chloride is used for the preparation of many other potassium compounds, including the hydroxide and the carbonate. More than 90% of the potassium chloride produced is used as a fertilizer.

Potassium bromide, KBr, is prepared by the reaction of bromine and potassium hydroxide:

The bromate decomposes upon heating to form more of the bromide:

Another method of preparation utilizes a solution of ferric and ferrous bromides, a by-product from one of the technical processes for the production of bromine. The iron bromides react with potassium carbonate solution,

and the ferrosiferrous oxide is removed by filtration. Potassium bromide is also obtained from natural brines. It is used in the preparation of photographic emulsions, in process engraving and in medicine as a sedative.

Potassium iodide, KI, is prepared by the reaction of iodine and potassium hydroxide solution:

Upon evaporation and further heating, usually after the addition of some charcoal, the iodate decomposes, yielding more iodide. The iodate may also be reduced to the iodide in solution by bisulfite ion, stannous ion or a suitable metal such as iron. Iodine dissolves in solutions of potassium iodide by forming the complex tri-iodide, KI_3 ; higher polyiodide ions containing an odd number of atoms, I_3^- , I_5^- and I_7^- , are formed in very concentrated solutions. Upon evaporation of the KI_3 solution, dark-blue or black crystals of the salt are obtained. Potassium iodide is used in the manufacture of photographic emulsions, in organic chemical syntheses, in animal and poultry feed, in table salt and in some drinking waters. In medicine it is used with iodine for the treatment of hyperthyroidism, and the salt containing radioactive iodine is used in the study and treatment of thyroid cancer. For the oxyhalogen salts see BROMINE; CHLORINE; IODINE.

Sulfur Compounds.—Potassium sulfate, K_2SO_4 , a constituent of a number of saline minerals, is a colourless or white compound crystallizing in the rhombic form. Its density is 2.66 g. per cubic centimetre, melting point $1,067^\circ \text{C.}$, refractive index 1.4947 and solubility 24.1 g. per 100 g. of water at 100°C. It is used in fertilizers, as an antifeed agent in smokeless powders and in the manufacture of potassium alums, potassium carbonate and glass.

Potassium bisulfate, KHSO_4 , is a white, deliquescent substance with a density of 2.4 g. per cubic centimetre and melting point of 210°C. At a high temperature it is converted to the pyrosulfate:

It is soluble in water, the solution being somewhat acidic because of the ionization of the HSO_4^- ion. Electrolysis of the solution yields the sparingly soluble potassium peroxydisulfate, $\text{K}_2\text{S}_2\text{O}_8$. Potassium bisulfate is used as a flux in the analysis of ores and as a chemical intermediate.

Potassium sulfite, K_2SO_3 , is prepared by saturating a solution of potassium hydroxide or carbonate with sulfur dioxide. It exists in the anhydrous form, the monohydrate and the dihydrate, $\text{K}_2\text{SO}_3 \cdot 2\text{H}_2\text{O}$, the latter being the commonest. The solubility of the salt is fairly constant over a wide range of temperature.

Potassium sulfide, K_2S , is a yellow or yellowish-red crystalline substance. It may be prepared by the direct combination of potassium and sulfur or by the reduction of potassium sulfate with carbon or hydrogen. In water solution it is strongly alkaline because of the extensive hydrolysis of the sulfide ion. Upon treatment with sulfur, polysulfides, K_2S_n , with as many as six sulfur atoms are formed. The salt has little use except as a laboratory reagent and a depilatory. See SULFUR.

Potassium nitrate, KNO_3 , also called nitre or saltpetre, is a white crystalline salt with a density of 2.11 g. per cubic centimetre, a melting point of 333°C. and a refractive index of 1.5038. It decomposes at 400°C. to potassium nitrite, KNO_2 , and oxygen. Since the quantity of the salt obtained from natural deposits is limited, it is prepared by the reaction either of synthetic nitric acid and potassium hydroxide or of naturally occurring potassium chloride and sodium nitrate. It is used in the manufacture of fireworks, gunpowder, fluxes and glass and for curing meats, pickling, tempering steel and impregnating candle wicks. See NITRIC ACID AND NITRATES; NITROGEN.

Determination.—Potassium may be identified by its emission spectrum or by the violet colour which its compounds impart to the Bunsen flame; if sodium is present the violet flame is masked and can be observed only through a suitable filter such as cobalt glass. Potassium may be identified and gravimetrically determined in the presence of the alkali metals by precipitation as potassium cobaltinitrite, $\text{K}_3\text{Co}(\text{NO}_2)_6$. Ammonium cobaltinitrite is insoluble and similar in appearance to the potassium salt. It is therefore necessary to eliminate ammonium ion from a sample before testing for potassium. Other gravimetric methods involve the precipitation of potassium perchlorate or of potassium chloride. The flame

photometer is also used to quantitatively determine potassium. Another procedure involves the elution of the sample with hydrochloric acid in an ion exchange column. The potassium ion moves through the column at a characteristic rate and the solution carrying it is collected, evaporated and weighed as potassium chloride.

PHARMACOLOGY

The principal salts and preparations of potassium used in medicine are the following:

Potassium acetate has been recommended in cardiac arrhythmias, potassium arsenite solution (Fowler's solution contains 1% of arsenic trioxide) for chronic myelogenous leukemia and psoriasis. Potassium bicarbonate is used as antacid and to alkalize urine. Potassium bitartrate (cream of tartar) has been used as a laxative and dusting powder; large doses can cause renal damage. Potassium bromide is used as a sedative and as an antiepileptic. Potassium chlorate has been used as an astringent in conditions such as stomatitis and Vincent's angina. Potassium dichromate has been used externally as an astringent, antiseptic and caustic; industrial contact may result in ulceration of the hands and destruction of mucous membranes; internally it is a corrosive poison. Potassium glycerophosphate has been used as a tonic. Potassium guaiacolsulfonate (thiocol; orthocol) has been recommended as an expectorant. Potassium hydroxide occasionally is used as a caustic; it is extremely corrosive. Potassium permanganate is used as an astringent, antiseptic and oxidizing agent in 1:100 to 1:10,000 solutions; toxic symptoms include emesis, profuse salivation, rapid respiration and albuminuria. Potassium phosphate, monobasic, is used to acidify urine; large doses are cathartic. Potassium sodium tartrate (Rochelle or Seignette salt) is used as a diuretic and as a cathartic. Potassium sulfate is used as a cathartic; it is a powerful irritant, and excessive doses may be fatal. Potassium tartrate (soluble tartar) has been used as a cathartic.

Toxicology.—The symptoms of poisoning by potassium hydroxide or other caustic alkalis are violent pain in the throat, vomiting and collapse. If not immediately fatal, stricture of the esophagus may develop. In emergency treatment the patient is given large amounts of dilute acetic acid (1%), vinegar (1-4%), citric acid (1%) or lemon juice, followed by milk or whites of egg beaten with water. Vomiting should not be induced.

See ALKALI MANUFACTURE; see also references under "Potassium" in the Index.

POTATO. The potato, common potato, white potato, or Irish potato, is one of the eight main food crops of the world, differing from the others in that the edible part of the plant is a tuber, i.e. the swollen end of an underground stem.

The word potato derives from the Spanish *patata* (itself derived from *batata*, the American Indian word for the sweet potato, *Ipomoea batatas*, of which the succulent tuberous roots are eaten). It first referred to the sweet potato (*q.v.*), which was known in England in the 16th century before the common potato. The term was then used indiscriminately for both sweet and common potatoes; and, by the end of the 17th century, almost always for the common potato, which was by then better known to English-speaking people. This article describes the potato, and discusses its cultivation and use throughout the world, as follows:

I. BOTANICAL CLASSIFICATION

The cultivated potato, considered by many to be a native of the Peruvian-Bolivian Andes, is one of approximately 150 tuber-bearing species of the genus *Solanum*. The name *Solanum tuberosum* was given to it in 1596 by Gaspard Bauhin, after its introduction into Europe. Linnaeus in 1753 called it *Solanum tuberosum*, and described it from what presumably were tetraploids (i.e., plants with doubled sets of chromosomes). The great majority of cultivated potatoes are tetraploids (with 48 chromosomes), but an appreciable proportion of those grown in South America are diploids (with 24 chromosomes). Triploids, heptaploids, and hexaploids also exist. Potato cultivation in South America dates back at least to the 2nd century A.D.—probably much earlier—as evidenced by the finding of dried potatoes and pottery decorated with potato motifs in graves of that age. Interbreeding and progeny selection from species taken into cultivation, and from polyploids arising from these, have led, in the course of centuries, to the sharing of a common genetic “pool” by nearly all cultivated potatoes wherever they are grown: and this forms the basis for the cultivated species *S. tuberosum*. Members of it exhibit considerable variation, depending upon which of the pool-derived characters are dominant, but there is no consistent basis for separating them into more than one species (although this has been attempted, e.g., by establishing a species, *S. andigenum*, to include potatoes growing under short-day conditions in the north of South America). See EVOLUTION, ORGANIC; Theories of Evolution; Mutation Theory; PLANTS AND PLANT SCIENCE: Morphology of Plants.

II. DESCRIPTION

1. Structure and Composition of the Tuber.—A potato tuber consists of about 10,000,000–100,000,000 cells, each 0.1–0.2 mm. in diameter and joined by pectin, gaps between them giving interconnected airspaces amounting to 1–2% of the volume. Aeration by these spaces maintains concentrations of about 18% oxygen and 3% carbon dioxide at the centre of an average tuber respiring at 0.2 millilitre per 100 grams' weight per hour at 10° C (50° F). Most cells consist of a cellulose wall lined with protoplasm, in which are insoluble constituents such as starch grains, surrounding an aqueous solution of the soluble constituents. The tuber has a corky skin pierced by lenticels through which occurs gaseous exchange. Metabolism continues at a slow rate after harvest and during storage. The vascular system through which the materials for the growth of the tuber were conveyed is discernible 0.5–1 cm. below the skin, rising to the surface at the “eyes” and at the point of attachment to the plant. Starch occurs in highest concentration adjacent to this system.

The content of dry matter of a tuber normally ranges from 18 to 28%, depending upon the variety (responsible for half of the variation), and upon maturity and growing conditions. Average figures for some important constituents, expressed as percentage of dry weight, are: starch, 70–75%; sugars, both reducing and nonreducing, approximately 0.5–1% each (but reaching over 10% if the tuber is immature or stored below 5° C); total nitrogen, 1–2%; protein nitrogen, 0.5–1%; ascorbic acid (vitamin C), 0.02–0.04%, but partly lost during storage; and citric acid, 2–5%.

2. Description of the Plant.—The potato is a herbaceous plant, 0.5–1 m. high. Its stems, usually angular in section, vary in posture, thickness, branching, colour (from green to deep purple), pubescence, and other characters. Leaf arrangement is spiral; leaves are compound and 20–30 cm. long, consisting of a terminal leaflet and two to four pairs of leaflets, each from about 6 to more than 10 cm. long, varying in shape and symmetry, but at least half as broad as they are long; there is also a variable number of small secondary leaflets. The inflorescence, on a stalk up to 20 cm. long, consists of several flowers on pedicels 1–4 cm. long. Frequency and duration of flowering are extremely variable. The corolla of the flower is wheel-shaped, five-lobed, 2–3 cm. in diameter, and varies in colour from white or pale yellow to deep reddish or bluish-purple, often tipped or striped with white. There are five erect stamens, with large (about 7 mm. long) anthers converging around the pistil. They open by terminal pores, and

POTATO (*SOLANUM TUBEROSUM*) SHOWING (LEFT) UNDERGROUND STEMS AND TUBERS, (RIGHT) FLOWER AND FRUIT

(A) Single flower. (B) Fruit cut across to show placenta and developing ovules. (C) Longitudinal section through flower. (D) Ripe anther opening and shedding pollen. (E) Longitudinal section through ovary. (F) Fruit

vary in symmetry and also in colour, from pale yellow (associated with male sterility) to deep orange. The ovary is two-celled, the style single, the stigma bilobed. The fruit is a globular berry, green to purple and poisonous, 15–25 mm. in diameter, with 100–300 seeds, embedded in mucilage. Underground stems (stolons) extend from the stem below ground. The roots are fibrous, adventitious, arising in groups of 3 at the stolon nodes (though seedlings from true seed have a tap root). The ends of the stolons may enlarge greatly to form a few to more than 20 tubers, of variable shape and size, usually ranging in weight up to 300 g. but occasionally to more than 1.5 kg.; their total weight may be more than 2 kg. Their skin varies from brownish white to deep purple in colour, and their flesh normally from white to yellow, but it is occasionally purple. The tubers bear spirally arranged buds (“eyes”) in the axils of aborted leaves, of which scars remain. These buds may remain dormant after the tuber is fully grown, even under conditions favourable to their development, for up to more than 10 weeks. They grow into plants identical with the plant that bore the tubers (except for occasional aberrant forms). Vegetative propagation of desired characteristics is thus possible; and this method is always used commercially because of the great variation that results when plants are grown from true seed. True seed is used only for the production of new varieties.

3. Varieties.—Plants grown from potato seeds, even from the same berry, may be very different not only in morphological features but also in commercially important characteristics, such as their response to climatic factors, their time of maturity, yield, disease resistance, cooking quality, suitability for industrial use, and keeping qualities. Commercially successful varieties have arisen in the past from the seeds of casual and often unknown crosses. This has become rare, however, because established varieties of reasonable quality and yield no longer “degenerate” and disappear from commerce as was once the case (see below); and hence a new variety must compete with the best of the surviving old ones, some of which have been on the market since the 1890s. The modern potato breeder is usually a geneticist who is trying to introduce some definite character—such as resistance to *Phytophthora* (late blight)—and selects his breeding material accordingly. From the progeny of his crosses he selects those uniting the quality he is seeking with the best combination of other characters, and propagates them vegetatively for some years, until a sufficient quantity of seed-tubers has been built up for the commercial introduction of the variety. Some varieties so introduced become established; others show unsuspected defects in cultivation and disappear in a few years.

Varieties are grouped according to their response to climatic conditions; the purposes for which they are fitted; and their

earliness or otherwise in producing a crop. Most commercial varieties yield best in temperate climates with long summer days. Others yield best under tropical, short days, if at high altitudes where temperatures are not excessive. Some are grown for industrial use, the main requirement being a high content of starch; others are for the table. Some are early varieties that form a crop after a short growing season, providing the first fresh potatoes of the year; others are late varieties, but giving a higher yield. Intermediately come second early and midseason or early main-crop varieties.

Rarely, varieties may be of international importance. Although the number in commerce in the 20th century must have been of the order of 1,000, relatively few were important. Even these cannot here be enumerated, but examples of categories of modern long-day varieties are:

Industrial: Stärkeregis, Irene, Deodora, Voran.

Culinary, early: Erstling (or Duke of York), Juli, Irish Cobbler, Arran Pilot.

Culinary, second early: Bintje, Eigenheimer, Cherokee, Craig's Royal.

Culinary, midseason: Alpha, Record, Chippewa, Majestic.

Culinary, late: Birgitta, Ackersegen, Russet Burbank, Kerr's Pink.

III. HISTORY OF POTATO GROWING

The potatoes cultivated on high ground in South America 1,800 years ago probably consisted of a haphazard mixture of varieties; as they do in parts of the same area today, where, though tetraploids are the most numerous, any type from diploid to hexaploid may be grown in the same field, and all be harvested and marketed together. Potatoes were not introduced into Europe from South America until the second half of the 16th century, having earlier been encountered and described by Spanish invaders. The exact date and source of their introduction is unknown. Judging from material in old herbariums, the original tubers were probably tetraploids from the north of South America. They possibly were shipped to Spain from Cartagena, Colombia. European herbalists were growing and describing the potato plant at the end of the 16th century, and during the next half-century it spread throughout the physic gardens of Europe. It was supposed to possess, among other vices and virtues, some potency as an aphrodisiac; and even to this day a slice of potato may be carried in the pocket, or even the handbag, by some who cling to the belief it has powers as a specific against rheumatism.

The staple food crops in Europe were rye, wheat, oats, and barley, grown in quantities normally adequate for the population. The potato was first added to this list in Ireland. There, as the systems of land tenure and inheritance led to farms of inadequate size, the introduction of a high-yielding crop was favoured, for the yield of the potato was many times that of any grain, and, despite its high water content, the food value obtained per acre of land was greater also. Moreover, political unrest and local warfare, in which whole areas were sometimes devastated, often caused the destruction of standing crops, or prevented the harvesting of any that survived; but the potato was little harmed, and could be dug when required. By the end of the troubled 17th century it was a major crop in Ireland; by the end of the 18th century (probably as a result of Irish experience) it was a major crop in continental Europe, particularly Germany, and in the west of England. The Irish economy itself had become dependent on it. A typical Irish peasant family consumed an average of more than 3.5 kg. (about 8 lb.) of potatoes per person per day. In other parts of the world where European settlement was proceeding, *i.e.*, North America, Africa, India, Java, and Australasia, the potato was introduced as a food crop, and, where conditions were suitable for its culture, assumed some importance. It continued to spread during the first four decades of the 19th century; but the disastrous failures of the Irish crop in 1845 and 1846, due to late blight (*Phytophthora infestans*), and the ensuing famine and disease, led to a more cautious attitude toward it. (See IRELAND: History: The Union: The Great Famine.) Its cultivation subsequently decreased in areas which had been dependent upon it.

In the early 1960s annual world production was about 280,000,000 metric tons, of which, in round figures, 30% was grown in the U.S.S.R., 15% in Poland, and 10% in West Germany; 5% in East Germany, in France, and in the United States; about half this latter amount in the United Kingdom and in Czechoslovakia; and smaller quantities throughout the rest of the world. Production per head of population was greatest in Poland—about 1,200 kg. (2,646 lb.).

IV. YIELD

Under good growing conditions, with good cultivation and fertilizing, yields of 30–35 metric tons per hectare (ha.; 2.471 ac.) are common. Much of the world's production is necessarily on soils and in climates which are not ideal, and includes the results of inefficient as well as efficient agricultural systems. The average yield over the whole world is about 11 metric tons per hectare, national averages ranging from under 6 metric tons per hectare in Peru to 25 metric tons per hectare in Ireland and the Netherlands.

1. Environmental Requirements.—*Light.*—Tubers are formed from starch synthesized by the foliage in the light, surplus to the foliage's own requirements. Under daylight lasting 15–17 hr. (up to 24 hr. within the Arctic Circle) the foliage is large and long-lived, with initially large demands on its starch production and late formation of tubers which then grow rapidly because of the large photosynthesizing surfaces of the foliage. Under short daylight (about 12 hr.) the foliage is smaller and short-lived, with early formation of tubers, which then grow more slowly owing to the lesser photosynthesis of the smaller foliage. Varieties differ in the length of daylight at which they strike the best compromise between these opposing effects and give maximum yield. Potato production is mainly in areas with 15–17 hr. of daylight during the growing season, and most commercial varieties have been selected to give maximum yields under these conditions.

A fully exposed potato leaf photosynthesizes carbon dioxide at a rate dependent upon the light intensity, rising from zero at dawn to 20–25 milligrams (mg.) per square decimetre (dm.) of exposed leaf surface per hour for some hours in the middle of a clear day and falling to zero again at dusk. Shading of one leaf by another reduces the maximum rate, averaged over the whole foliage, to about 15 mg. per dm.² per hr. On a cloudy, though bright, day it is further reduced to about 10 mg. and on a very dull day to about 1 mg. If the crop is irrigated, the yield is greater, depending upon light intensity, because of enhanced photosynthesis; but in the absence of irrigation, the positive effect of light on yield may be obscured by the negative effect of water shortage, which often accompanies prolonged clear weather.

Water.—Normally 3–5 mm. of rain or irrigation water are required to replace the water removed from moist soil by potato plants and lost to the atmosphere through evapotranspiration. Replacement by rain involves overcast or cloudy periods, during which photosynthesis and tuber growth are slow. But without regular rain or irrigation the soil dries out, leading to incipient wilting and closing of the pores of the leaves; absorption of carbon dioxide ceases, causing lack of growth. If rain is the only water supply, about 10 mm. per week provides the best compromise between these opposed effects. Supplemental irrigation twice a week to bring the daily average of water to 3–5 mm. gives better yields. Supplemental irrigation is preferable to an excess of rain weather. (See also IRRIGATION: Supplemental Irrigation.)

Temperature.—Temperatures fluctuating between 20° C (68° F) during the day and 14° C (about 57° F) during the night are best. Yield may be negligible at mean temperatures as high as 24° C, although short daylight hours partly counteract this effect. Daylight hours as long as those within the Arctic Circle necessitate low temperatures if any potato crop is to be obtained.

Soil.—The soil should be friable and uniform, without root formations and stones, for these obstruct root and stolon growth and cause formation of uneven tubers and difficulties in cultivation and harvesting. Water retention should be good; hence sands and soils with sand or gravel subsoil, are not among the most suitable. Rich silts are best.

2. Fertilizer and Manuring.—Every metric ton of potatoes harvested removes from the soil about 4 kg. of nitrogen and potassium, 0.4 kg. of phosphorus, and smaller quantities of many other elements, some essential to growth. A good crop removes far more than can be replaced naturally; and if the plants (as in the wild state) are not manured, the weight of tubers produced is small, and adequate only for the natural function of vegetative reproduction. Such a crop is useless commercially; manuring may increase it more than tenfold.

Elements are leached out of or fixed by soil in different proportions varying with the soil and the locality. The best proportions in which to add elements vary, therefore; but on most types of soil they are about 1 part of nitrogen, 0.4 of phosphorus, and 0.8–1.6 of potassium. On heavy fen or marsh soils the proportion of phosphorus should be increased to 0.9–1.3. Some soils in the western United States need no added potassium, and some muck soils no nitrogen. Broadly speaking, applications of fertilizer may be calculated from the above proportions, taking nitrogen as 190 kg. per ha. on good potato soils and as 125 kg. per ha. on soils that are poor for reasons other than lack of nutrients (e.g., because of scanty water supply) and on which, therefore, heavy fertilizer applications are wasted.

The elements are added in forms such as the following: ammonium sulfate (20–21% nitrogen); crude potassium sulfate (c. 40% potassium) or chloride (muriate of potash; 50% potassium); superphosphate (8%–9% phosphorus); and dung (0.6% nitrogen and potassium, 0.15% phosphorus—but only a fraction of each of these is available in the first year after application). Manure, though an inefficient source of the major nutrients, has beneficial effects on soil texture and on water retention; when used, 25–50 metric tons of it should be applied per hectare, supplemented by chemical fertilizers. Where agriculture is mechanized and stock-farming unimportant, applications of manure are often reduced or omitted. Compost, a plowed-in green crop (or, in coastal areas, seaweed) sometimes replace it. Manure is plowed in, either in the fall, or (where the annual rainfall exceeds 75 cm.) preferably in the spring. Chemical fertilizers may be broadcast and worked into the soil during spring cultivations before planting; but the preferred method is to place them in bands beside and beneath the seed-pieces at the time of planting. In many countries, compound potato fertilizers are available, providing nitrogen, potassium, and phosphorus in proportions best suited to the local soil. Many other elements are required in smaller quantities; they are usually present in the crudely purified chemical fertilizers, in manure, or as the produce of soil weathering; but any deficiency in them will have adverse effects on yield. Calcium (which may be deficient on acid soils, particularly if rainfall is high and application of potassium is lavish) is artificially added as lime; but this should not be done immediately before the potato crop is grown as it increases infection by scab. Magnesium deficiency in acid peat and sandy soils can be cured by applying magnesian limestone. Calcareous soils with free drainage may exhibit iron deficiency, which is treated by spraying the foliage with 0.2–1% ferrous sulfate. Deficiency in manganese and boron sometimes occurs in soils low in clay; the manganese deficiency can be rectified by spraying the foliage with 1% manganese sulfate, and the boron deficiency by plowing in borax in a proportion of about 20 kg. per ha.

In view of the frequent presence of chlorides in fertilizers, it is of interest that every 100 kg. of chloride added per hectare may reduce yield by nearly 450 kg. per ha.

(See also FERTILIZERS AND MANURES.)

3. Planting, Cultivation, and Harvesting.—Seed-tubers of about 50–60 g. weight are best for planting; but larger tubers cut into seed-pieces may be used. Planting is done as soon as conditions are suitable. Maximum yield from each individual plant would be obtained by spacing at a minimum of about 0.7 m. apart; but this would result in insufficient plants for best use of the land. In practice, the ground is cultivated and drawn into furrows, spaced, according to soil, climate and local custom, at 60 to 100 cm. apart. In these the seed-pieces are placed 15 to 60 cm. apart, according to the characteristics of the seed and the type of crop

desired; and the ridge is split over them. Usually, the larger the seed-piece the more tubers it will produce; and, if these tubers are to grow to marketable size, the plants must be spaced farther apart. If the crop is being grown for seed, however, close spacing is employed to give the maximum yield of suitably small tubers. Varieties differ in the number of stems and tubers produced from a seed-piece of given size—though this characteristic may be modified by adjusting the storage conditions of the seed. Optimum spacing therefore also differs according to the variety. Depth of planting varies from 5 to 10 cm., the former being usual if rapid emergence is desired.

In some regions, planting is done by hand; in others, plowing, placement of the fertilizer, planting, and covering of the seed are all done by one machine (see PLANTING MACHINERY).

Cultivation after planting to control weeds is held to a minimum to avoid damaging the plants. It is possible to control weed growth by preemergence herbicides, and cultivation is then unnecessary (see also WEED). In that case the ridges are sometimes harrowed down before the plants emerge and the crop is grown "on the flat." This has the advantage of hastening emergence and, on dry soils, of conserving moisture.

In regions where infection or damage is likely, the crop is sprayed or dusted against blight, and against pests such as aphids and Colorado beetle. If the foliage is diseased or likely to interfere with harvesting, it is destroyed, either mechanically or by spraying with a herbicide before harvest is begun.

Harvesting methods vary from digging by hand (in peasant communities); through plowing up, followed by lifting of the tubers by hand; to mechanized harvesting (in which the tubers, separated from soil, are delivered into a trailer). Even complete harvesting machines, however, need a crew to remove diseased and damaged tubers, stones, and clods of earth.

In regions where the climate permits, two crops of potatoes may be grown in one year.

(See also FARM MACHINERY; HARVESTING MACHINERY; TILLAGE MACHINERY; SPRAYS AND DUSTS IN AGRICULTURE.)

4. Diseases and Pests.—Most diseases exist in several strains, to each of which potatoes may be susceptible in differing degrees. Resistance to disease may take the form of hypersensitivity of the potato, which removes foci of infection by rapid death; or of biochemical depression by the potato of the growth and reproduction of the causative agent. The seriousness of diseases and pests varies in different regions and in different years according to the prevailing weather.

Foliage Destruction.—Late blight (*Phytophthora infestans*), the most widespread and destructive disease, may rapidly destroy the whole foliage when the weather is humid and daytime temperatures fluctuate between 10° and 25° C (about 50° and 78° F). Early blight (*Alternaria solani*) may be equally destructive under hot, dry conditions—the optimum temperature for it is about 27° C—but at lower temperatures it usually only produces brown "target spots" on the leaves. The progress of both diseases may be delayed by frequently spraying or dusting the foliage with copper sulfate or various dithiocarbamates; preferably the latter. Many countries operate a local radio warning service, based on weather reports, in order that spraying against late blight may be started in time. (See also PLANT DISEASES; FUNGI.)

Insect pests may eat the foliage, the seriousness of this varying with both pest and weather conditions. The potato flea beetle (*Epitrix cucumeris*), for instance, may eat holes in the leaves, giving a shot-hole appearance; but the Colorado potato beetle (*Leptinotarsa decemlineata*) will, if uncontrolled, eat the whole foliage except the stems (see POTATO BUG). Tuberworms (the larvae of a moth, *Gnorimoscheca operculella*), burrow in the stems and leaf midribs. Leafhoppers (*Empoasca fabae*), in feeding on the leaves, introduce toxins which cause necrosis (hopper burn) at the tips and margins of the leaflets: in hot dry weather the whole plant may be destroyed. Insect pests are controllable by, for example, DDT-containing sprays.

Stunting of the Plant or Shortening of Its Life.—Stunting, often accompanied by crinkling and yellowing of the leaflets, is a symptom of secondary virus infection, i.e., it is the result of growing

crops from tubers from infected plants. There are several causative viruses (designated as A, X, Y, leaf-roll virus, etc.), disseminated, with one main exception (X, which may spread by contact), by insects feeding first on diseased and then on healthy plants; the chief insects are aphids, flea beetles, and leafhoppers. It is therefore wisest to produce seed-tubers in localities where sources of infection, or the insect vectors, are not prevalent; and this is a major feature in seed certification schemes. Widespread infection of seed stocks, with consequently stunted plants and negligible yields, has caused "degeneration" of varieties. Recognition of this cause in the second decade of the 20th century, and the subsequent introduction of seed certification, were major factors in its eradication.

Stunting and premature death also result if the root system or conducting strands are attacked, with resultant obstruction of water and nutrient supply. Examples are infection by the fungi *Pellicularia filamentosa* (which normally may only produce black scurf on the tubers), *Sclerotinia sclerotiorum*, *Verticillium albo-atrum*, *Fusarium oxysporum* and *F. solani* var. *eumartii*; infection by the bacteria *Pectobacterium carotovorum* var. *atrosepticum* (blackleg), *Pseudomonas solanacearum* (brown rot) and *Corynebacterium sepe-donicum* (ring rot); and attack by the eelworms *Heterodera rostochiensis* and (less frequently) *Ditylenchus dipsaci*.

Biochemical Interference with Photosynthesis or Conduction.—Photosynthesis may be reduced by lack of chlorophyll, as in several secondary virus infections; and by lack of carbon dioxide in plants that have wilted because of interference with water supply (as mentioned above). Failure of the synthesis of sucrose, in which form carbohydrates are translocated from leaves to tubers, is a symptom of primary leaf roll infection.

Interference with Channels of Conduction to the Tuber.—This obviously leads to loss of yield, and may result in the formation of aerial tubers from carbohydrates that accumulate above ground. Infection by the fungus *Pellicularia filamentosa* may give this result.

Destruction of the tuber is caused by the fungi *Synchytrium endobioticum* (wart, or black wart), *Phytophthora infestans* (late blight), several species of *Fusarium* (dry rot), *Phoma foveata*; and by the bacteria *Pectobacterium carotovorum*, *Pseudomonas speurepsens*, *Pseudomonas solanacearum*, and *Corynebacterium sepe-donicum*.

Damage to the tuber is caused by slugs, potato tuberworm, wireworm (*q.v.*), the fungi *Streptomyces scabies* (common scab) and *Spongospora subterranea* (powdery scab); and by mild attacks from the destructive organisms mentioned above.

(See also PLANT DISEASES; PLANT QUARANTINE.)

5. Quality and Use.—In countries where an appreciable quantity of potatoes is grown, annual consumption per head varies from 27 kg. (Bulgaria) to 240 kg. (Poland). Annual consumption in the United States is 47 kg. and in the United Kingdom 88 kg.; in these two countries, most potatoes are grown for eating. In the chief producing regions of Europe, however, a large proportion of the crop is grown for stock feed and for industrial use.

One hundred grams of cooked potato, without addition of fat, provide about 70 calories (an equal quantity of bread gives about 200 calories); and about 10–30 mg. of ascorbic acid, depending upon how long the potatoes had been stored. This, in view of the large quantities regularly eaten, makes the potato an important source of vitamin C; and outbreaks of scurvy followed shortages of potatoes in Ireland in 1847, in Norway in 1904 and 1912, and in the United States in 1916. Hydrolysis of potato protein yields all the amino acids essential for nutrition, though the content of protein is variable. On the average, nitrogen equilibrium could be attained by the daily consumption of about 3 kg. potatoes (which, incidentally, would provide the total requirements of thiamin and nicotinic acid).

The cooking quality can be judged largely from the texture and colour of the cooked flesh. Mealiness is directly correlated with the percentage of dry matter, and so is partly dependent on the variety, as is the yellowness or otherwise of the flesh and any proneness to graying after cooking. The colour of fried potatoes

depends mainly upon the content of reducing sugars, which are caramelized during frying. A low content of these sugars, i.e., about 0.2% fresh weight, gives the usually desired pale colour.

Inferior potatoes are often used as stock feed; but potatoes are often grown especially for this and for industrial use. For both purposes they are inefficient, because of their low dry matter content; but the yield of dry matter per unit area of ground is greater than that of most crops. When this is more important than industrial efficiency, potatoes are used as a source of starch, and hence also of dextrins, alcohol, and other derivatives.

6. Storage.—Potatoes may be stored simply by piling them in the field in a long heap about 1 m. high, and by covering them with straw, 15 cm. thick, laid vertically from ground to ridge. This covering is capped with straw bent over it, and with a layer of soil 15–30 cm. thick. In cold climates the cover may be duplicated. A storage cellar is commonly used for home storage.

Where potatoes are grown commercially, it is more usual to store the crop in buildings. These should be weatherproof, insulated to prevent frost penetration and to enable the potatoes to be held at the desired temperature. Storage may be in one large mass 3 m. or more high (1 metric ton of potatoes occupies about 1.6 m³ in 50–100-ton bins; or in crates holding 1 ton or less. Ventilation ducts are frequently placed under the potatoes, often with provision for forced ventilation, with outside air, air recirculated in the building, or a combination of both. Refrigeration is sometimes necessary in hot countries. (See also FARM BUILDINGS; Crop Storage.)

At storage temperatures below 4° C (about 40° F), rotting and sprouting are negligible, but marked sweetening occurs. At temperatures of 8–15° C, which retains the sugar at a desirable level, both rotting and sprout growth present problems. For the latter chemical suppression may be used; by previously spraying the growing crop; by dusting the harvested tubers; or by ventilating them with the vapours of suppressants. Prevention of rotting takes precedence over other storage requirements, and, if disease is present, may require much more forced ventilation, and a lower temperature, than would be used if the tubers were healthy.

Potatoes, being alive, respire, producing about 10 kilocalories of heat per metric ton per hour—more when freshly harvested, immature, sprouted, or diseased—and this, if they are heaped together, raises the temperature of the mass. This in turn causes convective air exchange between the stack and the surrounding air, which removes heat, and, with healthy mature potatoes a balance is eventually struck in which the heat is removed by the convection as fast as it is produced. At this stage, the maximum temperature, and the convection activated by it, are dependent upon the height of the potato stack. (If the height is *h* metres the maximum potato temperature is about 1.5 h° C above the 24-hr. average temperature of the surrounding air.) The minimum temperature is about 1° C above average ambient temperature. With forced ventilation, the temperature range in the stack is much reduced, temperatures throughout being held within about 1° C of that of the surrounding air.

Weight is lost, otherwise than through rotting, mainly by evaporation of water, which is highest just after harvest, and when sprouting has occurred. With storage in bulk without forced ventilation, loss is restricted while with forced ventilation, the loss is increased. If the potatoes are in crates, air exchange is so free that temperatures are uniform and not much above that of the surrounding air; but weight losses are equal to the losses with continuous forced ventilation.

POTATO BUG, an agricultural pest (*Leptinotarsa decemlineata*), also known as the Colorado potato beetle, which attacks the leaves of potato plants. This leaf beetle (family Chrysomelidae), native to the western United States, originally fed upon a wild plant of the potato family, *Solanum rostratum*, abounding in the Rocky mountain region. With the westward movement, the cultivation of potatoes was brought to the beetle's

LYNWOOD H. CHACE

COLORADO POTATO BEETLE (LEPTINOTARSA DECEMLINEATA)

neighbourhood, and the insect at once took to the cultivated plant and began an eastward spread. By 1864 or 1865 it had crossed the Mississippi river into Illinois, and in 1874 it reached the Atlantic seaboard. As it progressed, certain predatory insects and various birds became accustomed to it, and as early as 1869 the insecticide paris green was used against it; so that by the time the beetle reached the Atlantic, potato growers in the midwest were able to control it. From 1945 the annual loss caused by the Colorado potato beetle has ranged about \$40,000,000.

Upon the advance of this pest great alarm was expressed in Europe. The German government early in 1875 issued a decree against the importation of U.S. potatoes. Similar action was taken the same year by Belgium, Spain, France, Russia, Italy, Hungary and Austria, and by Portugal and Sweden the following year. In spite of the German decree, the beetle was discovered in a potato field near Hamburg, but was exterminated by radical measures.

In 1922 the beetle was found to have been introduced near Bordeaux, France, in a region where there had been large numbers of American troops. From that region it has since spread, rather slowly, and infestation by the Colorado potato beetle is now general in France, the Netherlands, Luxembourg, Germany and Spain. It also occurs in much of Portugal and Switzerland and in parts of Austria, Yugoslavia, Czechoslovakia and Poland. It has been found sporadically in England, but repressive measures are believed to have exterminated the species.

The adults are oval shaped, about $\frac{3}{8}$ in. long, and are orange coloured with black stripes running lengthwise along the wing covers. Both the adult beetles and the larvae feed upon potato leaves. The extensive work of the insect on the foliage may often affect the quality of the tuber, and at one time it was difficult to obtain potatoes that were not watery when cooked. The adult beetles pass the winter underground, and in the spring emerge about the time that potato plants come through the ground. Females lay from 300 to 500 eggs over a five-week period on the undersides of leaves; there are one to three generations per year, depending on the latitude.

The leaf-feeding larvae always descend to the ground to turn into pupae. The insect feeds on nearly all plants of the potato family, including eggplant, tomato and tobacco. The tender-leaved varieties of potato are most affected however.

Many chemical mixtures such as DDT or arsenical compounds control the adults and larvae. Some growers apply DDT in combination with the recommended fungicide for their area. Resistance of the beetle to DDT has been reported in some localities.

Information may be obtained from the U.S. department of agriculture or agricultural experiment stations in affected areas.

POTATO WAR: see BAVARIAN SUCCESSION, WAR OF THE. **POTAWATOMI**, an Algonkian tribe of North American Indians whose name connotes firemakers (with flints or a one-stringed bow). Their culture, language, and particular traditions

unite them to prehistoric Ojibwa (*q.v.*) and Ottawa of the eastern woodlands, as is affirmed by 17th-century Jesuit accounts. Like other Algonkians, the Potawatomi migrated west from the Atlantic seaboard, partly under Iroquois pressure (see ALGONKIAN TRIBES). Observed in 1670 on islands around Green Bay, Wis., they spread south into lands that became Michigan, Wisconsin, Illinois, and Indiana. In the 1700s the tribe joined the French against the Iroquois and was allied with Pontiac (*q.v.*) in his uprising; it aided British forces in the American Revolution and opposed England in the War of 1812. Crowded by settlers, the so-called Potawatomi Nation moved west of the Mississippi River; some in Indiana escaped from the U.S. military into Canada. In 1846 most Potawatomi were removed by U.S. soldiers to a Kansas reservation where they became known as the Prairie Band of their tribe. During the westerly trek, they borrowed such alien Plains lifeways as communal bison hunts (replacing pursuit of woodlands game and fish), associated camp organizations, and the intertribal sign language that was generally understood throughout the Plains area (see PLAINS INDIANS).

In 1861 most of the Kansas band decided to take and sell their lands in severalty; after disputes, many moved (1868) to Oklahoma Indian Territory and were called Citizen Potawatomi. Despite the schism and the Citizens' assimilation to the dominant U.S. life, the two groups have maintained contact with each other, with the impoverished Forest (or "Stray") Potawatomi who fled to Wisconsin, and with the Huron Potawatomi who went to Michigan (1830s). Separation favoured social and linguistic differences among the bands, though many Citizens returned to the Kansas reservation. The Prairie Band cherishes its reservation as a home for aboriginal culture, which actively blends crafts and values with aspects of colonial and contemporary white culture. A resurgence of traditional religion and magic (dating from the 1930s) and a general acculturation were proceeding vigorously during the 1960s. At that time the U.S. government reported Potawatomi reservation population as follows: Kansas 830, Oklahoma 277, Wisconsin 246, and Michigan 134. (R. LA.)

POTEMKIN, GRIGORI ALEKSANDROVICH, PRINCE (1739–1791), Russian army officer and statesman, for two years the lover of the empress Catherine II and for 17 years the most powerful man in the empire, was born at Chizevo in Belorussia, on Sept. 24 (new style; 13, old style), 1739, the son of a nobleman of Polish descent (Potemski was the original family name). Educated at Moscow University, he entered the horseguards in 1755. He took part in the *coup d'état* of 1762, which brought Catherine II to power as empress; and Catherine made him a *Kammerjunker* and gave him a small estate. He distinguished himself in the Turkish War of 1768–74, and in March 1774 he became Catherine's fifth favourite. She bestowed on him the highest honours, including the post of commander in chief and governor-general of "New Russia" (Ukraine). In 1776 he was superseded in the empress's amorous graces by Zavadovski; but relations between her and Potemkin continued friendly, and his influence was never seriously disturbed by any of her later favourites.

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

GRIGORI POTEMKIN, ENGRAVING DATED 1789

Potemkin was deeply interested in the question of Russia's southern boundaries and so in the fate of the Turkish Empire. In 1776 he sketched the plan for the conquest of the Crimea, which was subsequently realized; and he was busy with the so-called Greek project, which aimed at restoring the Byzantine Empire under one of Catherine's grandsons. In many of the Balkan lands he had well-informed agents. After he

became field marshal, in 1784, he introduced many reforms into the army and built a fleet in the Black Sea, which, though constructed of bad materials, did excellent service in Catherine's second Turkish War (1787–92). His stupendous activity had admirable results: the arsenal of Kherson, begun in 1778, the harbour of Sevastopol, built in 1784, and the new fleet of 15 ships of the line and 25 smaller vessels, were monuments of his genius. But there was exaggeration in all his enterprises. He spared neither men, money, nor himself in attempting to carry out a gigantic scheme for the colonization of the Ukrainian steppes; but he never calculated the cost, and most of the design had to be abandoned when but half finished. Even so, Catherine's tour of the south in 1787 was a triumph for Potemkin, for he disguised all the weak points of his administration (hence the apocryphal tale of his erecting artificial villages to be seen by the empress in passing). On this occasion he received the title of prince of Tauris.

When the second Turkish War began, the founder of New Russia acted as commander in chief. But the army was ill-equipped and unprepared, and Potemkin, in a hysterical fit of depression, would have resigned but for the steady encouragement of the empress. Only after A. V. Suvorov had valiantly defended Kinburn did he take heart again and besiege and capture Ochakov and Bender. In 1790 he conducted the military operations on the Dniester and held his court at Iasi with more than Asiatic pomp. In 1791 he returned to Saint Petersburg, where, along with his friend A. A. Bezborodko, he made vain efforts to overthrow the new and last favourite, Platon Zubov. The empress grew impatient and compelled him (1791) to return to Iasi to conduct the peace negotiations as chief Russian plenipotentiary. He died on Oct. 16 (N.S.; 5, O.S.), while on his way to Nikolayev.

Potemkin was indubitably the most extraordinary of all Catherine's favourites. He was an able administrator, licentious, extravagant, loyal, generous, and magnanimous. Nearly all the anecdotes related of him by the Saxon diplomat G. A. W. von Helbig and freely utilized by later biographers are worthless.

See Theresia Adamczyk, *Fürst G. A. Potemkin* (1936); G. Solov'yichik, *Potemkin*, 2nd ed. (1949). (R. N. B.; X.)

POTENTILLA, the generic name for the cinquefoils, plants of the rose family (Rosaceae, *q.v.*), comprising more than 300 species, mostly herbs, widespread in North Temperate and Arctic regions, many being cultivated as border and rock garden plants. Various species bear brilliant flowers in white, yellow, or red, and graceful foliage. A good loamy soil, enriched with rotted manure, is most suitable.

Cinquefoils are easily propagated by seed or by division of the rootstocks; rootstocks, separated in early autumn or early spring, will generally produce blooms the succeeding growing season. Some perennial species are used in the garden border—*P. argrophylla*, with whitish hairs on the underside of the leaves; *P. grandiflora*, with large, showy, golden yellow flowers; *P. tormentilliformosa*, a much cultivated hybrid, with trailing stems and yellow flowers with a red centre—while others are good in the rock garden—*P. nitida*, a mat-forming species barely two inches high, with pink or white flowers one inch across; *P. multifida*, a spreading type up to four inches high, with small yellow flowers, two or three in a cluster. The shrubby cinquefoils, *P. fruticosa* and its varieties, provide a number of attractive flowering small shrubs for the garden.

POTENZA, chief town of the province of the same name in the region of Basilicata, south Italy, and an episcopal see. It stands 2,700 ft. above sea level in the Apennines near the upper Basento River, 56 mi. (90 km.) E of Salerno. Pop. (1961) 44,063

(commune). Notable churches are the cathedral (rebuilt 1799); the Romanesque S. Michele (11th–12th century); S. Francesco (1274), with Gothic apse and priceless carved wooden doors; and the small 15th–16th-century church of S. Rocco. The town has several times been rebuilt after earthquakes. The Museo Provinciale Lucano has an important archaeological collection. Potenza is a railway junction on the Salerno–Taranto line. The inhabitants are mostly engaged in agriculture and much of the abundant market gardening and orchard produce is exported.

Roman Potentia (founded c. 2nd century B.C.), which stood on a lower site than the modern town, was an important road junction and became a flourishing imperial *municipium*. In the 6th century it passed to the dukes of Benevento and thereafter to a succession of feudal owners. In 1806 the French made Potenza capital of Basilicata. In 1860 it was the first south Italian town to drive out the Bourbons. (See also BASILICATA; LUCANIA.)

POTENZA PROVINCE is watered by the upper courses of the Agri, Basento, Bradano, and Sinni rivers, and is traversed by the Apennines. Area 2,527 sq. mi. (6,545 sq. km.). Pop. (1961) 414,968. Agricultural products include cereals, fruit, olives, and grapes; and there is stock raising (sheep and goats). The province has many mineral springs and lignite and marble deposits. It was, until 1927 when Matera Province was detached, coextensive with Basilicata. (M. T. A. N.)

POTGIETER, ANDRIES HENDRIK (1792–1852), a Boer leader in the Great Trek, best known for his part in establishing Boer settlement in the Transvaal, was born in the eastern Cape Colony on Dec. 19, 1792, and with his trekker party left the colony late in 1835. Joined by other trekkers, they halted near Winburg, north of the Orange River (February 1836). As commandant and leader, Potgieter treated with local Bantu tribes to establish Boer title to the land. He clashed with the hostile Matabele (1836–37) and won the battle at the Marico River (November 1837), which opened the high veld interior to the Boers. After the massacre of Piet Retief (February 1838), he joined an unsuccessful expedition in Natal against the Zulu king Dingaan, but returned to Winburg in May 1838, convinced that the destiny of the trekkers lay northward. His ideal was an anterior republic, remote from British influence, but linked commercially with the Portuguese at Delagoa Bay. He founded three settlements in the Transvaal: Potchefstroom (1838) in the southwest, Andries Ohrigstad (1845) in the northeast, and one in the Zoutpansberg (1848), the northernmost region colonized in the Great Trek. Partly through his efforts, Boer republicanism enjoyed a continuous history in the Transvaal during this period, in contrast to its fate in Natal and the future Orange Free State. As a leader Potgieter exercised authority along local, military, and patriarchal lines. In the conflicts within the Transvaal trekker community (see TRANSVAAL: History), as head commandant he supported the military party against the *volksraad* (elected council) and favoured local autonomy rather than the establishment of a centralized state. When Great Britain recognized the independence of the Transvaal Boers in the Sand River Convention (Jan. 17, 1852), he held aloof from the negotiations, which were conducted on the Boer side by his rival Andries Pretorius, but in March he ratified the Convention. He died in the Zoutpansberg on Dec. 16, 1852.

POTGIETER, EVERHARDUS JOHANNES (1808–1875), Dutch prose writer and poet, who tried to set new standards and encourage national consciousness in his journal *De Gids* (founded 1837), and anticipated the literary revival of the 1880s. He was born at Zwolle on June 27, 1808. His initial optimism is evident in *Jan, Jannetje en hun jongste kind* (1842), an allegory satirizing the people's mental inertia; in *Het Rijksmuseum* (1842), a homage to 17th-century Holland and to the prose style of P. C. Hooft (*q.v.*) which it follows; and in *Liedekens van Bontekamp* (1840), songs in the 17th-century manner.

The resignation of the historian Bakhuizen van den Brink from the editorial board of *De Gids* in 1843 left Potgieter with a sense

J. MORACE MCFARLAND CO.

PURDOM BUSH CINQUEFOIL (POTENTILLA PURDOMI)

of frustration and gloom until his confidence in the possibility of a literary revival was restored by the critic Conrad Busken Huet (q.v.). His subsequent work includes *Onder weg in den regen* (1864), the best of many subtle and often humorous sketches and short stories; *Florence* (1868), a long poem in tercets written after a visit to the city for the Dante centenary; and *De Naiantschap van de Landjonker* (1875), a poem cycle by a fictitious aristocrat which amply justifies the trouble required to master his highly individual style. He died on Feb. 3, 1875.

(P. K. K.)

POTHIER, DOM JOSEPH (1835–1923), French monk and scholar who, together with his contemporaries, reconstituted the Gregorian chant (see PLAINSONG). Born at Bouzemon, near Saint-Dié, on Dec. 7, 1835, he took vows as a Benedictine monk at Solesmes in 1860. He was prior of Ligugé in 1893 and in 1898 was appointed abbot of Saint-Wandrille. Soon after he entered Solesmes he collaborated with Dom Paul Jausions on a new edition of the choir books based on manuscripts of the Gregorian chant. Dom Jausions died in 1870 but his contribution was acknowledged in the preface to Dom Pothier's publication *Les Mélodies grégoriennes d'après la tradition* (1880), which became the standard work on the subject. In 1883 he published the *Liber gradualis*, which also included research earlier undertaken by Dom Jausions and which, with the *Mélodies grégoriennes*, marked the beginning of a reform in liturgical chant. In 1889 he was associated with his disciple Dom André Mocquereau (1849–1930) in the foundation of the publication *Paléographie musicale* for the dissemination of medieval liturgical manuscripts. In 1904 Pope Pius X appointed him chairman of a commission for the reconstitution of the music of the Roman Catholic Mass. Many of the controversial theories regarding the intervention of Gregorian chant were published in the *Revue du chant grégorien* (1892–1914), of which Dom Pothier was editor. He died at Conques, Belg., on Dec. 8, 1923.

See M. Cocheril, "Dom Joseph Pothier," *Encyclopédie de la musique*, ed. by F. Michel, vol. iii (1961); Abbé M. Blanc, *L'Enseignement musical de Solesmes et la prière chrétienne* (1953).

POTI, a town and port of the Georgian Soviet Socialist Republic, U.S.S.R., stands on the Black Sea at the mouth of the Rioni River, on the site of the ancient Greek colony of Phasis. Pop. (1959) 42,068. The modern town developed only in the 19th century, when in the 1880s an artificial harbour and a rail link to the main Trans-Caucasus Railway at Mikha Tskhakaya were built. Its chief exports are manganese from Chiatura, cotton, and citrus fruits; coal, grain, sugar, and fertilizers are the main imports. There is a fishing fleet and fish-processing works. Dredgers are built at Poti, and there is a flour mill, a meat packing plant, and a refrigeration plant.

(R. A. F.)

POTLATCH, meaning giveaway in Chinook (q.v.) trade jargon, the public distribution of property as uniquely and elaborately institutionalized among American Indians of the North Pacific Coast. The potlatch existed in the following cultures, reading from southern Alaska to northern Oregon: Tlingit, Tsimshian, Haida, Bella Coola (qq.v.), Northern and Southern Kwakiutl, Nootka, Coast Salish, and Lower Chinook. Although each group had its characteristic version, the potlatch had certain general features. Ceremonial formalities were observed in inviting guests, in speechmaking, and in the distribution of goods by the donor according to the social rank of the recipients. The size of the gatherings reflected the rank of the donor; often large, they tended to include guests from a wide territory. Great feasts and generous hospitality accompanied the potlatching, and the efforts of the kin group of the host were exerted to maximize the liberality. The proceedings gave wide publicity to the social status of donor and recipients since there were many witnesses.

Nonutilitarian prestige property was most appropriate for such distributions; useful goods were given in quantities far beyond normal needs. A potlatch was given by an heir or successor to

assert and validate his newly assumed social position. Important steps such as marriage were frequent occasions for potlatches, but just as often such trivial events as the first time a baby's hair was singed served equally well. The main purpose was the validation of any and all claims to social rank. Among the Tlingit the potlatch centred around mourning the death of an important chief; among the Tsimshian and Haida the potlatch memorialized a chief and established his successor. The Kwakiutl and Nootka potlatched for these and other reasons, most frequently to affirm and reaffirm social rank. They also had the face-saving potlatch to wipe out such losses of dignity as falling into the water in public view, and the competitive potlatch in which two rivals in social rank vied even to the point of destroying property. Coast Salish potlatches were usually given by established village leaders as reconfirmation of their worth.

The potlatch reached its most elaborate development among the Southern Kwakiutl from 1849 to 1925. The whole culture focused on the institution; their potlatches were the most frequent, distributed the greatest amount of property, and were the most complex financially. Interest-bearing loans, and coppers (shield-shaped pieces of copper) serving as negotiable checks for credit and property, were native inventions supporting the potlatch.

The recipient had to return greater value when it came his turn to potlatch; in their expanding economy these prosperous people distributed extraordinary amounts of property. In ceremonies lasting days, thousands of blankets and other European goods including motorboats, sewing machines, enamelware, clothing, flour, and sugar were distributed along with such native goods as masks and canoes. The donor of such a potlatch required several years to prepare, earning Canadian money (usually in commercial salmon-fishing), and making loans to fellow Kwakiutl probably for their own potlatching. Considering the lengths to which they went to make potlatching their most absorbing institution, the Southern Kwakiutl burlesque through a play potlatch is remarkable. By the 1960s traditional potlatching had virtually ceased, even where enthusiasm for it had run highest. Economic factors were more to blame than were interests working for Indian assimilation.

(HE. C.)

POTOCKI, the name of a Polish aristocratic family known in southern Poland since the 13th century. Its seat was Potok, near Jędrzejów. The founders of the family's power were the sons of MIKOLAJ (1517–1572), namely JAN (1555–1611), ANDRZEJ (d. 1609), JAKUB (1554–1613), and STEFAN (d. 1631), who distinguished themselves in wars against the Tatars. During the Zebrzydowski insurrection (1606–07; see POLAND: History) they fought at the side of King Sigismund III.

MIKOLAJ (d. 1651), son of Jakub and hetman of the crown, was in command of the Polish forces at the victorious Battle of Beresteczko (1651; see UKRAINIAN SOVIET SOCIALIST REPUBLIC: History). STANISLAW (1579–1667), son of Andrzej, was also hetman of the crown, and took part in battles against Wallachians, Muscovites, Cossacks, Turks, and Swedes. In 1660 he defeated the Muscovites at Cudnow; and in 1662 he founded the city of Stanislawow (Ivano-Frankovsk). His sons ANDRZEJ (d. 1692) and FELIKS KAZIMIERZ (d. 1702), both hetmans, took part in the Turkish wars of King John III Sobieski.

In the 18th century the Potockis were among the most prominent "republicans" opposing Kings Augustus II and Augustus III and the Familia (party of the Czartoryskis and the Poniatowskis). JOZEF (d. 1751), son of the hetman Andrzej, was a partisan of Stanislaw Leszczyński during the Northern War (q.v.) and was made hetman by him. Since his baton was taken away during the restoration of Augustus II, he again supported Leszczyński during

the interregnum of 1733. Having formally reconciled himself with Augustus III, he became again hetman in 1735. Leader of the "republicans," he sought French, Turkish, and Prussian support against the Saxon dynasty. In this he had the help of his distant cousin TEODOR (1664–1738), primate of Poland from 1722, who as *interrex* in 1733 had procured Leszczyński's election as king.

FRANCISZEK SALEZY (d. 1772), grandson of Feliks Kazimierz, palatine of Kiev from 1756 and the richest magnate of his times, became reconciled with the court after the break between Augustus III and the Familia; but under King Stanisław II Poniatowski the Potockis were again in opposition.

The firmest supporter of the "republican" tradition was STANISŁAW SZCZESNY or FELIKS (1752–1805), the son of Franciszek Salezy and heir to immense estates in Ukraine. He dreamed of transforming Poland into a federal republic (without a king), following the example of the United States of America. He was palatine of Ruthenia and later general of the crown artillery. In 1785–89 he was grand master of Polish freemasonry. In favour of friendly relations with Russia, he opposed the alliance with Prussia (1790) and the monarchical constitution of May 3, 1791. Head of the Confederation of Targowica, which was formed with the Russian military aid in 1792 to annul the enactments of the "Four Years' sejm," he did not foresee the second partition of Poland (1793). Disillusioned and branded as a traitor, he retired to his Tulczyn estates.

IGNACY (1751–1809), great-grandson of Feliks Kazimierz, was prominent in the Commission of National Education from 1773 and grand master of Polish freemasonry from 1781 to 1784. He advocated a reform to subordinate the government to a sovereign *sejm*. During the "Four Years' sejm," from 1788, he was a leader of the patriotic faction and promoted the alliance with Prussia and the constitution of May 3, 1791. After the Confederation of Targowica he emigrated to Dresden (1792–94) and helped to prepare Tadeusz Kościuszko's insurrection (1794). Having directed the foreign policy of the insurrectionary government, he surrendered to the Russians after the fall of Warsaw and was sent to St. Petersburg. On his return to Poland (1796) he settled at Klimontow and devoted himself to political writing. He died in Vienna in 1809, having gone there to present to Napoleon I a petition for the incorporation of Galicia in the Duchy of Warsaw.

STANISŁAW KOSTKA (1755–1821), many times deputy to the *sejm* and an outstanding orator, followed the politics of his elder brother Ignacy. After creation of the Duchy of Warsaw (1807) he was president of the council of state. Between 1812 and 1821 he was grand master of Polish freemasonry. In the Polish kingdom created by the Congress of Vienna he served as minister of education and church affairs (1815–20). He wrote many literary and political works, the most famous being the anticlerical *Podróż do Ciemnorodu* ("Journey to Backwash Towns"; 1820), for which he was dismissed from office.

JAN (1761–1815), explorer in Asia and Africa, archaeologist, historian, novelist, and journalist, first appeared as a deputy to the "Four Years' sejm." He wrote some notable historical works and travel books in French and also a fantastic novel, *Manuscrit trouvé à Saragosse* (new edition 1958).

ALFRED (1817–1889), a member of the Łańcut-Antoniny branch of the Potockis (made counts by Austria in 1768), served as Austrian prime minister in 1870–71 and as governor of Galicia in 1875–83. ADAM (1812–1872), deputy to the Vienna Parliament, became the leader of the Polish Conservative Party in Galicia, loyal to Austria. His son ANDRZEJ (1861–1908) was governor of Galicia from 1903 till a Ukrainian nationalist student shot him. The younger ALFRED (1886–1957), son of Roman and grandson of the Austrian prime minister Alfred Potocki, took over the *majorat* of Łańcut and left memoirs published as *Master of Łańcut* (1959). His brother JERZY (1889–1961) served as Polish ambassador to Turkey (1933–35) and to the United States (1936–40). Their uncle JOZEF (1862–1922), Roman's brother, administered the estates of Antoniny in the Ukraine; his title of count was confirmed by Russia in 1890. His son JOZEF (1895–), a member of the Polish diplomatic service from 1919, was ambassador to Spain in World War II. (E.M.R.)

POTOMAC, a river in the east central United States, rises in the Appalachian mountains of West Virginia and flows south-eastward into Chesapeake bay, draining an area of approximately 14,500 sq.mi. Its two headwaters, the north and the south branch, join about 15 mi. below Cumberland, Md. From there to the bay it is 287 mi. long, 117 of which are tidal. At Harpers Ferry it receives the Shenandoah river from the Appalachian valley to the south and after traversing the easternmost mountain chains through a series of spectacular watergaps it is joined by the Monocacy river in the Piedmont region and by the Anacostia or east branch at Washington, D.C. Together with its north branch, it forms the boundary between Maryland and West Virginia from its source to Harpers Ferry, and from there to its mouth it is the boundary between Maryland and Virginia. The District of Co-

COURSE OF THE POTOMAC RIVER

lumbia lies on its left bank at the head of tidewater. Navigability of the tidal portion is assured by channels dredged to a depth of 18 and 21 ft. at Washington and of 24 ft. through all the shoals. Washington and Alexandria (Va.) possess minor port facilities. The lower Anacostia is navigable to Bladensburg, Md., for small craft. For a stretch of about 12 mi. upstream from Washington the Potomac descends from the Piedmont to the coastal plain in a series of rapids and falls, of which Great Falls contains a cataract about 35 ft. high. The Chesapeake and Ohio canal, paralleling the Potomac, was completed in 1850 from Georgetown to Cumberland; traffic ceased at the beginning of the 20th century but the canal remains a scenic and recreational asset.

(F. O. A.)
POTOSÍ, a department of Bolivia, bounded north by Oruro and Cochabamba, east by Chuquisaca and Tarija, west by Chile and south by Argentina. Pop. (1961 est.) 608,000. Area 45,644 sq.mi. Situated in the southwest of the country, it ranks second in population and fourth in territorial area among Bolivia's departments. Potosí (q.v.) is capital of the department and of the province of Cercado. Indians, mestizos and people of European descent make up the population.

The department is noted for its great mineral wealth and its high physical altitude. The surface is extremely rugged, being traversed by the eastern branch of the Andes, and the climate is rigorous. Elevations range from about 6,000 ft. to more than 20,000 ft. above sea level. The capital city stands at an altitude of over 13,700 ft., and the temperature there seldom exceeds 59° F. Livestock grazing and agriculture are carried on, chiefly at lower elevations owing to the harsh natural environment of the Altiplano. Vegetation is scarce and there is little water for irrigation. The region is drained mainly by the affluents of the Pilcomayo. The department is also deficient in fuels, a significant obstacle to industrial development.

The Spanish mining industry in Bolivia began in 1540 with the operation of the silver mines of Porco (now the province of Quijarro) by Gonzalo Pizarro and Diego Centeno. The discovery in 1545 of Cerro Potosí, a conical mountain rising 15,680 ft. above sea level, established Potosí as the foremost silver producing region in the world. It is estimated that the region subsequently produced \$1,000,000,000 worth of silver. The Cerro is composed of one of the richest ore bodies yet discovered, an ore containing tin, bismuth and tungsten in addition to silver.

Potosí declined in importance as a mining area as a result of the diminution of the more readily available ores and of progress in technology which made feasible the use of lower quality ores in more accessible locations. The exploitation of Bolivia's tin ores which began shortly before the end of the 19th century restored mining activity in the department. The construction of a railway from Antofagasta to the centre of the plateau in 1892 made it possible to ship out ores of lesser value than those of silver; newly discovered uses for tin created an expanding market for that metal. Lead, zinc, antimony, copper, bismuth, sulfur, gold, silver and wolfram, are also worked in the region. Among the 13 provinces of the department, those notable for minerals comprise Sud Chichas (regarded as the richest), Cercado, Chayanta, Bustillo, Charcas, Linares, Alonso de Ibañez, Nor and Sud Lipez and Nor Chicas. Extensive deposits of solid salt, the Salar de Uyuni (3,500 sq.mi.) and Copaisa, Chiguana and Empexa, south of Lake Poopó, are also exploited.

Air, railroad and highway facilities are available within the department. A branch line of the Antofagasta-La Paz railway extends to the city of Potosí from the junction at Río Mulato. This line (15,705 ft. above sea level at Condor) is one of the highest railways in the world. (J. L. Tr.)

POTOSÍ, a city in Bolivia, capital of the department of Potosí, is located on a cold and barren plateau 275 mi. S of La Paz. Pop. (1961 est.) 54,374. One of the highest cities of the world (altitude over 13,700 ft.), it stands in the shadow of the fabulous Cerro Potosí and its 5,000 mines. The temperature seldom exceeds 59° F. Legend attributes the name to "potojchi," Quechua word meaning "thunder," on account of rumblings inside the mountain. The city came into existence after the discovery of silver in the cerro by the Indian Gualpa, whose master Juan de Villaroel registered the first claim April 21, 1545. Charles V conferred upon it the title Villa Imperial (1547). Philip II chartered the university (1571) and the mint (1572). So great was the wealth of the mines that "as rich as Potosí" became a current expression. About 200 merchants supplied the city with luxuries from all parts of the world. It was a turbulent city full of factions, such as the Vicunas and Vascongados, who waged full-fledged civil war, 1623-26. Population fluctuated with the mineral production. Of the estimated 160,000 residents in 1650 only 8,000 remained when Simón Bolívar liberated the area in the final battle of the Wars for Independence, Oct. 5, 1825. Rich tin deposits replaced the diminishing silver lode and 20th century Potosí became the leading industrial city of Bolivia. Iron, steel, shoes, soft drinks, beer, furniture, electric products, and mosaics supplemented mining (tin, lead, copper, silver) and refining industries.

Although flood and earthquake have taken their toll, Potosí retains its colonial charm. The city is laid out in squares with narrow, sometimes winding streets originating in the central plaza, around which are grouped the government house, city hall, national college, mint, treasury, and cathedral, dating back to colonial times. Potosí is on a highway, and the Sucre-Potosí Railway connects with the Antofagasta-Bolivia line.

See Lewis Hanke, *The Imperial City of Potosí* (1956). (G. B. Co.)

POTSDAM, a town of East Germany, the headquarters of the Bezirk (district) of the same name, in the German Democratic Republic. It is situated on the Havel, divided there into lakes, and is adjacent to the southwest boundary of Berlin. Pop. (1962 est.) 115,257. It was first mentioned in the 10th century as a Slav settlement and received its municipal charter in the 14th century. Under the Great Elector, Frederick William, it became a garrison town in 1640, and from the time of Frederick the

FRITZ ESCHEN

SOUTH FACADE OF SANSSOUCI PALACE

Great, to whom it owes many of its fine buildings, it was the summer residence of the Hohenzollerns. The Stadtschloss (reconstructed 1745-51, with splendid rococo interiors) and the nearby Garrison Church (1731-35) as well as most of the town centre were severely damaged by bombing attacks during World War II but restoration was later undertaken. The Brandenburg Gate (1770) stands near the entrance to the Sanssouci Park in which is the Sanssouci Palace (1745-47), the one-storied summer residence of Frederick the Great, a masterpiece of German rococo. The Neues Palais (1763-69) is now a teachers' training college. Other buildings of interest are Babelsberg Castle, built 1834-49 in the English Tudor style, the Friedenskirche (Church of Peace), erected in 1845-49 in the style of an early Christian basilica, and the Nikolai Church (1830-37).

Potsdam is an industrial town with scientific institutes, including the German academy of political science and law, the college of finance, the German academy of film art, and institutes connected mainly with agriculture and medicine. There are also the Einstein Observatory, a meteorological observatory, and a theatre. In Babelsberg (an incorporated suburb) are film studios, and the town has important industry including locomotive works, textile mills, and pharmaceutical factories.

For the Potsdam Conference (July 17-Aug. 2, 1945) see WORLD WAR II CONFERENCES, ALLIED.

POTTER, ALONZO (1800-1865), U.S. Protestant Episcopal bishop and educator, who by writing and lecturing did much to extend and improve public school education, was born at Beekman (now La Grange), N.Y., July 6, 1800. He graduated in 1818 at Union College, where he became tutor and then professor of mathematics after a brief period spent in studying theology at Philadelphia. He was a rector of St. Paul's, Boston, from 1826 to 1831, when he returned to Union as professor of philosophy and political economy, becoming vice-president of the college in 1838. He was consecrated bishop of Pennsylvania on Sept. 23, 1845. Potter died on board ship in San Francisco Bay on July 4, 1865.

Potter's chief work (with G. B. Emerson) was *The School and the Schoolmaster* (1842). He was particularly interested in work for young men and in temperance reform. As a legislator in the church he was wise and progressive. He established the Philadelphia Divinity School (1863) and laboured for the hospital of the Protestant Episcopal Church in Philadelphia.

See M. A. De Wolfe Howe, *Memoirs of the Life and Services of the Rt. Rev. Alonzo Potter, D. D.* (1870).

POTTER, (HELEN) BEATRIX (1866-1943), English writer and illustrator of books for young children, the creator of "Peter Rabbit," "Benjamin Bunny," "Jemima Puddle-Duck," "Mrs. Tiggy-Winkle," and other famous animal characters, was born in South Kensington, London, on July 6, 1866. Her father, a barrister, had never practised; both parents came of hard-headed Lancashire stock and had inherited cotton fortunes. Even by mid-

Victorian standards they were conventional and authoritarian, and Beatrix, their only daughter, spent a lonely and repressed childhood, enlivened only by annual holidays in Scotland or the Lake District. These gave her her first experience of the country and developed her artist-naturalist talent for drawing hedgerow animals, which she kept as pets and used as models for both naturalistic and imaginative watercolour drawings.

When she was 27, still living at home, she began sending illustrated letters to the sick child of a former governess, telling him stories about Peter Rabbit, Benjamin Bunny, and her tame hedgehog, Mrs. Tiggy-Winkle. These letters gave such pleasure that she decided to make Peter Rabbit into a book. *The Tale of Peter Rabbit* (1900) was privately published, as was *The Tailor of Gloucester* (1902). She eventually found a publisher, Frederick Warne & Co., who in the next 30 years brought out 23 of the little books which made her famous.

Despite strong parental opposition, in 1905 she became engaged to Norman Warne, the son of her publisher, and after his sudden death a few months later spent much of her time alone at Hill Top, a small farm in the village of Sawrey in Lancashire, bought with the proceeds of a legacy and the royalties from her books. In 1913 she married William Heelis, a solicitor from Ambleside, Westmorland, and spent the last 30 years of her life extending her farm property and breeding Herdwick sheep. She bequeathed her land to the National Trust, which maintains her original farmhouse as it was when she lived in it. She died at Sawrey on Dec. 22, 1943. After her death the Tate Gallery, London, acquired her watercolour illustrations to *The Tailor of Gloucester*. The only known portrait of her is in the National Portrait Gallery.

Beatrix Potter's books have been loved by generations of children and have been widely translated. They combine a deceptively simple prose, concealing a dry north-country humour, with illustrations in the best English watercolour tradition. In old age, as her sight deteriorated, she lost much of her freshness of vision, and her last few stories, written for publication in the United States, were poor both in style and draftsmanship. The best of these later works, *The Fairy Caravan*, was published in New York in 1929 and in London in 1952; it does not in any sense compare with her earlier masterpieces. In these, her animal characters are described with shrewd economy, and their homes and backgrounds—hedgerows, gardens, cabbage-patches, farmhouse kitchens—in the precise and homely detail that children love. There is nothing sentimental about her themes; there is even a macabre strain occasionally, for she is not squeamish and her eye is faithful to nature. Though her rabbits may wear shoes and jackets and her hedgehog a mobcap and pinafore, they are fundamentally true to their animal nature. Poetic vision and a robust regard for truth go hand in hand.

See M. Lane, *The Tale of Beatrix Potter* (1946); L. Linder and W. A. Herring, *The Art of Beatrix Potter* (1955). (M. L.A.)

POTTER, PAUL (PAULUS) (1625–1654), Dutch painter and etcher, celebrated chiefly as an animal painter, son of the painter Pieter Potter, was born at Enkhuizen in 1625. He entered the Guild of St. Luke at Delft in 1646. In 1649 he moved to The Hague, where in the following year he married Adriana, daughter of the architect Claes van Balkeneynde. In 1652 he settled in Amsterdam, where he died on Jan. 15, 1654. Potter probably received his early training from his father, but his style shows little dependence upon that of earlier masters. Animals appear prominently in all of Potter's characteristic works, sometimes singly (the "Grey Horse," dated 1653, Hamburg), more usually in small groups silhouetted against the sky, or in greater numbers with peasant figures and rustic buildings in an extensive landscape. So lifelike is his portrayal of cows, horses and other domestic animals that many critics tend to regard this as his only talent, and to treat him as one of the minor Dutch masters—charming, but limited in range. This is an undervaluation of Potter's genius. His range of subject matter is limited by his own choice, but within that range he displays powers far above many contemporaries who are usually judged to be more eminent. No Dutch painter of his time was more sensitive to the passing moods of nature, or to the countryside's timeless harmony of beast, landscape

BY COURTESY OF THE SALZBURGER RESIDENZGALERIE

"EARLY MORNING" BY PAUL POTTER, 1647

and weather, and none gives the impression of having observed the landscape of his country with deeper love or understanding. In addition, Potter possessed a remarkably developed feeling for design, expressed in the grouping of his forms and in his use of eloquent silhouette, dark on light or light on dark. All of these qualities can be admired in the superb "Early Morning" (1647, Salzburg museum), which is possibly his most perfect masterpiece. This is a fine, open composition, painted with a small, but firm and lively touch; the light of early morning—and of early spring—is deliciously rendered, and there is a keen understanding of both animal and human behaviour. Like most of his really successful pictures it is on a small scale, and painted on panel.

In so tragically short a career there was naturally little development in style between the earlier and the later works, but 1647 seems to mark a peak in his achievement, for many of the finest paintings bear this date. Characteristic works are: "Cattle in a Stormy Landscape" (1647; National gallery, London); "Horse Tethered at a Cottage Door" (1647 or 1649; Louvre, Paris); "Peasant With Cattle" (1648; Cassel) and "Cattle Reflected in Water" (1648; Mauritshuis, The Hague). Among works which depart from his normal scale or style, the huge "Young Bull" (1647; The Hague), which is on the scale of life, is his most celebrated though surely not his finest work, while "Orpheus Charming the Beasts" (1650; Rijksmuseum, Amsterdam), is an untypical excursion into a poetic world reminiscent of Roland Savery. Potter's etchings of animals show all the skill and sympathy of his paintings.

See T. van Westrheene, *Paulus Potter, Sa vie et ses oeuvres* (1807); C. H. de Groot, *Catalogue of ... Dutch Painters, etc.*, vol. iv (1912). (R. E. W. J.)

POTTERIES, THE, a name applied to a district of north Staffordshire, the principal seat of the china and earthenware industry in England. It lies in the upper part of the Trent basin. For a distance of 9 mi. from southeast to northwest and about 3 mi. from northeast to southwest, the district resembles one great town, but the chief centres are Burslem, Hanley, Longton, Stoke-on-Trent, Fenton and Tunstall (except Fenton, the "Five Towns" of Arnold Bennett's novels). These towns were amalgamated in 1910 as one municipal borough under the name of Stoke-on-Trent (*q.v.*), which was made a city in 1925. Newcastle-under-Lyme, though not sharing in the staple industry, may also be reckoned in the district. In 1769 Josiah Wedgwood founded potteries at Etruria, by the Trent and Mersey canal; they are now at Barlaston. Wedgwood and Minton are the two most famous family names connected with the china industry of the district. Coal from the north Staffordshire coal field, and coarse clay are the only local natural products used in the industry, the finer clay and other ingredients being brought from elsewhere.

POTTER'S CLAY: see KAOLIN.

POTTERY AND PORCELAIN. Pottery in its widest sense includes all objects made from clay and hardened by fire; the term porcelain applies only to certain kinds of pottery. The following article outlines the history of the art and manufacture of the principal types of pottery and porcelain throughout the world and is arranged as follows:

I. Introduction

1. Types of Earthenware
2. Types of Stoneware
3. Types of Porcelain
4. Methods of Fashioning Ceramics
5. Ceramic Figures
6. Decoration
7. Ceramic Marks
8. Forgeries
9. Scientific Analysis
10. Collections

II. History of Ceramics

I. INTRODUCTION

"Pottery" and "porcelain" are technical terms referring to the composition and method of manufacture of the material in question. Both terms require some explanation. Clay, the basic material of both pottery and porcelain, has two distinctive characteristics: it is plastic (*i.e.*, it can be molded and will retain the shape imposed upon it); and it hardens on firing to form a brittle, but otherwise virtually indestructible, material which is not attacked by any of the agents that corrode metals or organic materials. Also if a sun-dried clay vessel is filled with water it absorbs the liquid, becomes very soft, and eventually collapses, but if it is heated chemical changes that begin to take place at about 500° C preclude a return to the plastic state no matter how much water is later in contact with it. At extremely high temperatures, which are difficult to achieve in any kiln, the clay will eventually "vitrify," or fuse to form a glassy, nonporous substance. If, however, the clay is mixed with suitable proportions of more easily fusible material, the vitrification temperature can be lowered to around 1,200° C. The fusible material melts and seals the pores of the unfused clay which retains the original shape of the vessel. (For this reason the Chinese refer to the clay as "the bones" of the vessel, and to the vitrifying substance as "the flesh.") At temperatures between 1,250° and 1,450° C the vitrified substance becomes translucent.

The terms describing the end products of firing are sometimes used very loosely. In this article, all objects that are made from clay and hardened by fire are termed "ceramics," a word derived from the Greek *keramos* ("potter's earth"). This meaning corresponds with the French *céramique* and the German *Keramik*. "Pottery" is used synonymously with "earthenware" to denote all ceramic substances which are not vitrified. These are, in consequence, slightly porous and are coarser than vitrified materials, which may belong to one of two classes, "stoneware" or "porcelain." The line of demarcation between the last two is extremely vague. In Europe porcelain is usually defined as a translucent substance—when held to the light most porcelain will be found to have this property—and stoneware is regarded as partially vitrified material which is not translucent. The Chinese, on the other hand, define porcelain as any ceramic material which will give a ringing tone when tapped. None of these definitions is completely satisfactory: for instance, some thinly potted stonewares are slightly translucent if they have been fired at a high temperature, whereas some heavily potted porcelains are opaque. Therefore the application of the terms is often a matter of personal preference and they should be regarded as descriptive without being definite.

Earthenware, stoneware, and porcelain are all found in glazed and unglazed forms and, in the case of the first two, the type of glaze is often used as the basis for further classification within each category.

1. Types of Earthenware.—Primitive races made vessels of sun-dried clay which could be used only for storing cereals and similar dry materials. Early fired vessels held water, but, because they were still slightly porous, the liquid percolated slowly to the outside where it evaporated, cooling the contents of the vessel. Thus the porosity of earthenware was, and still is, sometimes an advantage in hot countries and the principle is utilized in the 20th century in the construction of domestic milk and butter coolers and some food-storage cupboards.

Porosity, however, had many disadvantages—*e.g.*, the vessels could not be used for storing wine or milk—and a remedy eventually was devised. This consisted of covering the surface with a thin layer of glass, termed a "glaze." The art of glazing for

decorative as well as practical purposes followed speedily upon its introduction (see *Primitive Pottery*, below).

There are two main types of glazed earthenware: the one is covered with a transparent glaze, and the other with an opaque white glaze.

Apart from some glazes made from feldspar which are, in effect, natural glasses, glazes in normal use are indistinguishable from manufactured glass. Some of the earliest glazes fall into much the same divisions as old glass (*i.e.*, soda glass or potash glass) but the introduction of lead as a flux, probably in the 1st century B.C., gave a glaze more suitable for soft earthenware because it fused at a much lower temperature. Lead glazes were employed in the 18th century in soft porcelain manufacture. Modern technology has produced new glazes which fall into none of these categories while remaining a type of glass.

Opaque white glazes are made by adding stannic oxide, one of the oxides of tin, to the glaze material. Wares thus decorated are often referred to as "tin enameled" or "stanniferous." Other terms in common use are "majolica" (Italian, *maiolica*), "faience," and "delft." These, again, are used by various authorities with different meanings and the position needs clarification. The art of tin enameling was discovered by the Assyrians who used it to cover courses of decorated brickwork. It was revived in Mesopotamia about the 9th century A.D. and spread to Moorish Spain, whence it was conveyed to Italy by way of the island of Majorca or Maiolica. In Italy tin-enameled earthenware was called *maiolica* after the place where it was mistakenly thought to have originated. The wares of Italy, particularly those of Faenza, were much prized abroad and early in the 16th century the technique was imitated in southern France. The term "faience," which is applied to French tin-enameled ware, is undoubtedly derived from "Faenza." Wares made in Germany, Spain, and Scandinavia are known by the same name. Early in the 17th century a flourishing industry for the manufacture of tin-enameled ware was established at the town of Delft, Holland, and Dutch potters brought the art of tin enameling to England together with the name of delft, which now applies to wares manufactured in the Netherlands and England. Some misleading uses of these terms include that of applying "*maiolica*" to wares made outside Italy but in the Italian style, and "faience" to Egyptian blue-glazed ware and certain kinds of Near Eastern earthenware. *Fayence-Porcellaine* was a term sometimes used in 18th-century Germany to describe faience decorated with enamel colours applied over the glaze, as on porcelain.

Tin enamel was undoubtedly devised in the first place to hide faults of colour in the body, for most clays contain a variable amount of iron which colours the body from buff to dark red. Tin-enameled wares look somewhat as though they have been covered with thick white paint. They sometimes received the addition of a lead glaze, known in Italy as *coperta* and in the Netherlands as *kwaart*.

Defects of body colour also suggested the use of slip, a mixture of clay and water with a creamlike consistency which is washed over the vessel before firing. Slips may be either white or coloured. A common mode of decoration is to incise a pattern through the slip revealing the body colour beneath, a technique which has received the generic term of *sgraffito* ("scratched") ware. Slip, too, is sometimes dotted and trailed in much the same way as a confectioner decorates a cake with icing sugar; the English slipwares of the 17th and 18th centuries are typical of this kind of work. Earthenware washed over with a white slip and covered with a colourless glaze is sometimes difficult to distinguish from lead-glazed tin enamel. In consequence it has sometimes been wrongly called faience. The term for French earthenware decorated in this way (in imitation of Wedgwood's creamware, is *faience fine* and in Germany it is called *Steingut*. *Messa-Maiolica* (Italy) and *Halb-Fayence* (Germany) refer to similar white earthenware with incised decoration.

2. Types of Stoneware.—Although glazed stoneware does not fall into such definite categories as glazed earthenware, to some extent it can be classified according to the kind of glaze used. The fine Chinese stonewares of the Sung dynasty (A.D. 960–1279)

were covered with a glaze made from feldspar, the same vitrifiable material as was later used in both the body and glaze of porcelain. Stoneware covered with a lead glaze is not uncommon, but perhaps the majority of extant glazed wares are salt glazed. In this process a shovelful of common salt (sodium chloride) is thrown into the kiln when the temperature reaches its highest. The salt splits into its components, the sodium combining with the silica in the clay to form a "smear" glaze of sodium silicate, the chlorine escaping through the kiln chimney. Salt glazes have a pitted appearance similar to that of orange peel. A little red lead is sometimes added to the salt, which gives the surface an appearance of being glazed by the more usual means.

A fine white stoneware, conventionally glazed, was made in Staffordshire, Eng., during the early years of the 19th century, and was termed "Ironstone China."

Of the unglazed stonewares, the most familiar are the Chinese teapots and similar wares from I-hsing in Kiangsu Province, the red stoneware body made at Meissen in Saxony during the first three decades of the 18th century and revived in modern times, and the ornamental basaltes and jaspers made by Josiah Wedgwood and Sons since the 18th century.

In the mid-20th century stoneware was used mostly for utility articles such as drainpipes and laboratory ware, and also by artist-potters such as Bernard Leach and his followers.

3. Types of Porcelain.—Porcelain is classified not by the type of glaze used, as is the case with earthenware and stoneware, but by the composition of the body. It was first made in a primitive form in China during the T'ang dynasty (A.D. 618–906). The kind most familiar in the West was not manufactured until the Yüan dynasty (A.D. 1280–1368). It was made from kaolin (white china clay) and petuntse (a feldspathic rock), the latter being ground to powder and mixed with the clay. During the firing, which took place at a temperature of about 1,450° C, the petuntse vitrified, while the refractory clay ensured that the vessel retained its shape. It was extremely difficult to attain an even distribution of heat throughout the kiln, and in some parts the temperature rose to a point where even the clay vitrified. The vessels that warped or melted to shapeless lumps are known as "wasters." All old pottery and porcelain factories accumulated "wasters," many of which have been subsequently excavated. They provide the most reliable evidence of the types of ware made and the position of sherds in the heap enables a system of sequence dating to be established.

In medieval times isolated specimens of Chinese porcelain found their way to Europe where they were much prized, principally because of their translucency. European potters made numerous attempts to imitate them and, since at that time there was no exact body of chemical and physical knowledge whereby the porcelain could be analyzed and then synthesized, experiments proceeded strictly by analogy. The only manufactured translucent substance then known was glass, and it was perhaps inevitable that glass made opaque with tin oxide (the German *milch-glas*, for example) should have been used as a substitute for porcelain. The nature of glass, however, made it impossible to shape it by any of the means used by the potter, and a mixture of clay and ground glass was eventually tried. Porcelain made in this way resembles that of the Chinese only superficially and is always termed "soft" or "artificial" porcelain. The date and place of the first attempt to make soft porcelain is debatable, but some Middle Eastern pottery of the 12th century was made from glaze material mixed with clay and is occasionally translucent (see *Islamic Pottery: Egypt*, below). Much the same formula was employed with a measure of success at Florence about 1575 at workshops under the patronage of Duke Francesco de' Medici. Specimens of this "Medici" porcelain are now very rare. No further attempts of any kind appear to have been made until the mid-17th century, when Claude and François Révérend, Paris importers of Dutch pottery, were granted a monopoly of porcelain manufacture in France. It is not known whether they succeeded in making it or not, but certainly by the end of the 17th century porcelain was being made in quantity, this time by a factory at Saint-Cloud, near Paris.

Spouted jar in the polychrome minoan style. Middle Minoan II, about 1850-1700 B.C. Height: 11 in.

Three-handled amphora (storage jar) in the palace style, decorated with stylized lilies. Late Minoan II, about 1450-1400 B.C. Height: 27½ in.

AEGEAN AND EGYPTIAN POTTERY

The jars at top are from the palace workshops at Knossos, where floral and marine motifs were effectively exploited. The flowers on the jar above are arranged into a symmetrical pattern in which it is hard to see where nature ends and abstraction begins. Closer to nature are the formally arranged lilies of the amphora at right. The aryballos (centre) is a miniature masterpiece of the orientalizing period: the lion's head follows a neo-Hittite model, while the battle scene reflects the early diffusion of epic poetry. The black-figure technique, already attempted on the aryballos, reaches perfection in the amphora below by Exekias, who endowed his figures with mood and emotion. The psykter shows the wider variety of pose and greater freedom of drawing made possible by the red-figure technique.

Aryballos (scent bottle) with mouth in the form of a lion's head. The three zones contain a hoplite battle, a horse race, and a hare hunt. Proto-Corinthian, about 650 B.C. Height: 2½ in. In the British Museum

Amphora in the black-figure style, signed by Exekias, showing Achilles slaying Penthesilea. Attic, about 530 B.C. Height: 16¼ in. In the British Museum

Psykter (wine cooler) in the red-figure style, signed by Douris, showing reveling satyrs. Attic, about 480 B.C. Height: 11¼ in. In the British Museum

Painted urn of red polished pottery with geometric decoration, from the Pan-shan cemetery, Kansu Province; about 2000 B.C. Height: 15 1/4 in. In the Victoria and Albert Museum

CHINESE POTTERY AND PORCELAIN

These two plates give a brief survey of Chinese ceramic art from Neolithic times to the 18th century. A period of 400 years stretched between the making of the Han censer (top right) and the T'ang figure (right). These four centuries—turbulent, characterized by western-nomad raids and the rise of Buddhism—were not favourable to ceramic art. Only during the T'ang dynasty were the nomads beaten back; the empire expanded greatly and contacts with the West resumed. The Sung dynasty, though another turbulent era, was the classic period of Chinese art. Sung pottery (bottom right) emphasized form and employed coloured glazes of great beauty and variety. Invading Mongols overthrew the Sungs and established the Yüan dynasty; the traditional Chinese white translucent porcelain decorated in underglaze blue, first produced under this dynasty, reached its peak under the Mings (below)

"Hill" jar, or censer, with a cover representing the Taoist "Isles of the Blest"; Han dynasty (202 B.C. - A.D. 221). Height: 9 1/2 in. In the Victoria and Albert Museum

Tomb figure decorated in characteristic coloured glazes; T'ang dynasty (A.D. 618-906). Height: about 2 ft., 4 in. In the Victoria and Albert Museum

Flask decorated with a dragon and wave scrolls in underglaze blue; Ming dynasty (1368-1644), 14th century. Height: 14 1/2 in. In the Victoria and Albert Museum

Dish of Lung Ch'üan celadon with incised decoration and four fish left unglazed; Sung dynasty (A.D. 960-1279). Length: 12 3/8 in. In the Victoria and Albert Museum

Pear-shaped bottle with long neck, painted in underglaze blue and overglaze enamels; Ming dynasty (1368-1644), signed with six-character mark of Wan Li (1572). Height: 21 in.

Vase of the *famille noire* painted with flowers of the seasons; reign of K'ang-hsi (1661-1722), Ch'ing dynasty (1644-1912), with mark of Ming emperor Ch'eng Hua (1464-87). Height: 18¼ in. In the Victoria and Albert Museum

Trumpet-shaped vase with floral decoration on background of green enamel, *famille verte*; reign of K'ang-hsi, Ch'ing dynasty. Height: 29 in. In the Victoria and Albert Museum

CHINESE PORCELAIN

If the Sung dynasty is regarded as China's classic period, then the Ming dynasty might be termed its baroque phase. The technical advances in production and decoration, the more extensive use of painting, and the great diversity of forms that characterized Ming ceramics may be seen in the exceptional example at top left. The Manchu Ch'ing emperors of the middle 17th and 18th centuries fostered the art of porcelain making and encouraged experimentation. This patronage led to such ambitious schemes of decoration as the *famille noire* (above), the better-known *famille verte* (top right) and the *famille rose* (left), the pigment for which was introduced from Europe and generally used to decorate wares made for export. The practice of painting on biscuit (right) was a development of the Ming *san ts'ai* wares which were still being produced during the Ch'ing period

Buddhist figure painted with *famille rose* enamels; reign of Ch'ien-lung (1736-96), Ch'ing dynasty. Height: 17 in. In the Victoria and Albert Museum

Vase of lobed form painted on biscuit with a yellow ground; reign of K'ang-hsi, Ch'ing dynasty. Height: 12¼ in. In the Victoria and Albert Museum

Japanese lobed dish with a bouquet of chrysanthemums in a paper holder; Kakiemon ware from Arita, about 1700. Diameter: 7 in.

Bottle of Japanese white porcelain decorated with enamel colours at Delft, the Netherlands; about 1730. Height: 30 in.

Pear-shaped bottle of Japanese Kutani porcelain decorated in characteristic enamel colours; about 1685. Height: 16 in.

JAPANESE AND KOREAN PORCELAIN

Japanese ceramics were strongly influenced by those of Korea and China. An exception was Kakiemon ware, originating in the 17th century, which made innovations in design and, in turn, influenced 18th-century porcelain makers in Europe. Kakiemon ware (top left) is noted for its white porcelain surface which enhances the asymmetrically placed painting. Much Japanese white porcelain (top right) was exported to Europe where it was decorated in enamelling studios. Kutani porcelain (above), seldom seen in European collections, is rich in colour, bold in design. The Korean bottle (right) exemplifies the rare and uniquely Korean technique of *mishima*, inlaying decoration under glaze.

Korean bottle with a celadon glaze and *mishima*, or inlaid decoration; Koryŏ dynasty, 13th century. Height: 13½ in. In the Victoria and Albert Museum.

Turkish jug characteristic of the decorated with a scale pattern, tin enamel glaze; Iznik (Anatolia), about 1575. Height: 11 in. In the Victoria and Albert Museum

Two examples of Persian pottery. (Left) Bowl painted in black and cobalt over a white slip; from Kashan, Iran; about A.D. 1200. Diameter: 7 $\frac{3}{4}$ in. (Right) Blue-glazed Seljuk bowl with carved decoration; about A.D. 1150. Diameter: 7 $\frac{1}{4}$ in. In the Victoria and Albert Museum

Persian jar with fish painted in black under a turquoise glaze; Sultanabad. Height: 11 $\frac{1}{4}$ in. In the Victoria and Albert Museum

Persian bowl painted with overglaze colours (*minai* technique); late 12th century. Diameter: 8 $\frac{3}{8}$ in. In the Victoria and Albert Museum

ISLAMIC POTTERY

All Islamic pottery is earthenware, usually fired at comparatively low temperatures and therefore extremely fragile. Perfect excavated specimens are very rare; the condition of the plate (top centre) is typical of the state in which most vessels are recovered. Abstract patterns and designs based on Kufic inscriptions are common decorative motifs; naturalistic representations of human beings and animals are found in Persian pottery but are rare elsewhere. The rediscovery of tin enamel (top left), lost since Assyrian times, was the major Islamic contribution to ceramic history and inspired the development of the European faience industry. Enameling on glaze, *minai* (above), was also an Islamic discovery, later copied in China during the Sung dynasty

Large Italian *maiolica* dish decorated with hunting scenes; signed by the potter and painter, dated 1594. From the Modena workshop. Diameter: 30 in. In the Hastings Museum

French dish painted in the *istoriato* style; Lyons, about 1575. Diameter: 15 in. In the Victoria and Albert Museum

EUROPEAN POTTERY TO THE END OF THE 18TH CENTURY

Italian *maiolica* or tin-enamel ware (left), noted for its technically brilliant painted decoration, was the distinctive pottery of the Renaissance. Influenced directly by the developing art of easel painting and by rediscovered classical motifs, *maiolica* set a fashion copied elsewhere in Europe, as in the French dish above, which was inspired by the *istoriato* style of pottery from Urbino. Seventeenth-century stoneware of the Rhineland (left), made to endure use in tavern and inn, was principally Late Gothic in style. English pottery figures owed little to continental sources. Lively and amusing figures such as the one below, are typical of English preindustrial work

Gray stoneware jug decorated with cobalt and salt glaze; from the Westerwald region, Germany. Early 17th century, English silver mounts dated 1652. Height: 9½ in.

An Astbury figure of a mounted dragoon; Staffordshire, Eng., about 1740. Height: 7⅞ in. In the Victoria and Albert Museum

Teapot with decoration in overglaze blue; Saint-Cloud, France, about 1720. Height: 5½ in. In the Museum of Fine Arts, Boston

Porcelain plaque with portrait of Empress Maria Theresa; Doccia, Italy, about 1750. Height: 12½ in. In the Victoria and Albert Museum

EUROPEAN PORCELAIN IN THE 18TH CENTURY

The development of artificial or soft-paste porcelain was primarily French and began in 1664 with the granting of a royal privilege for its manufacture to the Révérend brothers. Soon porcelain factories in several cities were producing distinguished works. Notable were the wares from the factory of the widow Chicaneau at Saint-Cloud (above). The early porcelain of Chantilly (right) imitated the Japanese *kakiemon* style but also introduced an important innovation, the use of tin-enamel glaze over a ceramic body. The royal factory at Sèvres made porcelain of great fineness and subtlety of colour (bottom right), well suited to the luxurious court life of the time. The French royal family, which owned the Sèvres factory, tried to maintain its monopoly by royal decree. It did not succeed entirely, as evidenced by the rare jug below, made at Mennecey, an unauthorized factory

Cachepot with flower painting in the *kakiemon* style of Arita, Japan; Chantilly, France, about 1740. Contemporary mounts. Height 9¾ in. In the Victoria and Albert Museum

Covered jug painted in enamel colours and mounted in ormolu (simulated gold); Mennecey, France, about 1760. Height: 9½ in. In the Victoria and Albert Museum

Vase and cover decorated in reserved panels by Morin; Sèvres, France, 1780. Made for presentation to King Gustavus III of Sweden. Height: 19½ in. In the Victoria and Albert Museum

Harlequin, from the *commedia dell'arte*, modeled by Johann Joachim Kändler; Meissen, Ger., about 1738. Height: 6½ in. In the Victoria and Albert Museum

Wine cooler with floral decoration; factory of Claudius, Vincennes, France, about 1740. Height: 6½ in. In the Victoria and Albert Museum

EUROPEAN PORCELAIN OF THE 18TH CENTURY

Eighteenth-century German and Austrian porcelain reflected both Baroque and Rococo influences. The vigorously modeled Harlequin (left) and the delicately painted wine cooler (above) are both masterpieces in the Baroque tradition. The Columbine (bottom centre) is an excellent example of the grace and charm characteristic of the period as well as an asymmetrical scrollwork base of unusual delicacy. While notable Rococo porcelain was made in England (bottom left and right), the Rococo style was not as fashionable there as it was in France, where it became fashionable as it conflicted with the stronger influences of the classical tradition and of the

English vase in the French Rococo style of Sèvres with mazarine blue ground and painted in reserved panels by John Donaldson; Chelsea, about 1760. Height: about 20 in. In the Victoria and Albert Museum

Columbine, from the *commedia dell'arte*, modeled by Franz Anton Bustelli; Nymphenburg, Ger., about 1760. Height: 7¾ in. In the Victoria and Albert Museum

"The Dancing Lesson," after a design by François Boucher; a superb example of the work of the period of the gold anchor at Chelsea, about 1763. Height: 18 in. In the London Museum

Pre-Columbian stirrup vase in the form of a portrait head; Mochloa culture, Peru. Height: 8½ in. In the British Museum

Mexican falena (tin-enamelled) jar in the style of the Spanish potters of Talavera de la Reina, New Castile; about 1775-1800. Height: 10¾ in. In the Metropolitan Museum of Art

POTTERY AND PORCELAIN OF THE AMERICAS

Pre-Columbian pottery (above) developed independently of outside influence, achieving a high level of quality. It declined with the coming of the Spanish in the 16th century. The first notable pottery to show European influence, Mexican falena (right), appeared about 1650. European immigrants, like the German settlers in Pennsylvania, used their own techniques and materials as much like those used in Europe as they could find (bottom right). Apart from a few attempts in the 18th century, American porcelain manufacture began with the fine wares of William Tucker (below)

Porcelain pitcher by William E. Tucker; Philadelphia, about 1830. Height: 9½ in. In the Brooklyn Museum

Red earthenware pie plate with sgraffito decoration, the design scratched through the slip; Pennsylvania-German style, early 19th century. Signed by David Spinner. Diameter: 11½ in. In the Brooklyn Museum

"Virginian Cardinal and Orange Blossom," from a series of American birds by Dorothy Doughty; Worcester Royal Porcelain Co., Worcester, Eng., 1938. Height: 11½ in.

Porcelain service plate decorated by Scottie Wilson; Worcester Royal Porcelain Co., 1965. Diameter: 10 in.

20TH-CENTURY POTTERY AND PORCELAIN

In Europe the art of porcelain making declined after the 18th century, largely because it was unsuited to the Neoclassical style then in fashion. In the ensuing years, Wedgwood's creamware and stoneware (below left) grew in popularity and gained an important position in the ceramic market. The renaissance of porcelain did not become apparent until after World War II, but its origin may be traced back to the 1930s when Dorothy Doughty designed a series of American birds (above). Some indication of the wide variety of styles that characterized post-World War II porcelain may be seen in the service ware (top right) decorated by the primitive painter Scottie Wilson, and the seal (right) from the Royal Copenhagen Porcelain factory

Modern coffee pot of traditional stoneware; Josiah Wedgwood & Sons, 1964. Height: 10½ in.

Porcelain plate and pitcher from the Sèvres coffee service designed by Frank G. Holmes, 1913. Lenox, Inc. Size, plate: 8¾ in. sq.; height, pitcher: 5½ in.

Seal; Royal Copenhagen Porcelain Co., 1906. Height: 11½ in.

The secret of "true," or "hard," porcelain similar to that of China was not discovered until about 1707 in Saxony when Ehrenfried Walter von Tschirnhaus, assisted by an alchemist called Johann Friedrich Böttger, substituted ground feldspathic rock for the ground glass in the soft porcelain formula. Since its discovery hard porcelain has been the body preferred on the European continent.

The terms "soft" and "hard" porcelain refer to the "soft" firing (about 1,150° C) necessary for the first, and the "hard" firing (about 1,450° C) necessary for the second. By coincidence they apply also to the physical properties of the two substances: for example, soft porcelain can be cut with a file, whereas hard porcelain cannot. This is sometimes used as a test for the nature of the body.

In the course of experiments in England during the 18th century a type of soft porcelain was made in which bone ash was added to the ground glass. Josiah Spode the Second later added this bone ash to the true, hard porcelain formula and the resulting body, known as bone china, has since become the standard English porcelain. Soft porcelain, always regarded as a substitute for hard porcelain, was discontinued because it was uneconomic; kiln wastage was excessive, occasionally rising to nine-tenths of the total. Hard porcelain is strong, but its vitreous nature causes it to chip fairly easily and, unless specially treated, is usually tinged slightly with blue or grey. Bone china is slightly easier to manufacture than hard porcelain. It is strong, does not chip easily, and the bone ash confers an ivory-white appearance widely regarded as desirable. Generally, bone china is most popular for table-services in England and the United States, although connoisseurs of the finer qualities of old porcelain usually prefer the hard variety.

4. Methods of Fashioning Ceramics.—The earliest vessels were modeled by hand. Almost as early, pots were made by smearing clay round the inside of a basket or coarsely woven sack. The

introduction of the "kick" wheel, rotated by foot, which became the potter's principal tool. The potter now centred the clay on a rapidly rotating disc and shaped his pot by manipulating it with both hands. This is a considerable feat of manual dexterity which led to much greater exactness and symmetry of form. Perhaps the most skilful of all potters have been the Chinese. Excellent examples of their virtuosity are the "double gourd" vases, made from the 16th century onward, which were turned in separate sections and afterward joined together. By the 18th century the wheel was no longer turned by the potter's foot but by small boys, and since the 19th century the motive power has been mechanical.

The use of molds is very ancient. The basketwork pottery described above is molding of a kind. A more advanced method, used by the Greeks and others, is to press the pottery body into molds of fired clay. Though the early molds were comparatively simple, they later became more complex, a tendency best seen in those molds used for the manufacture of pottery figures. The unglazed earthenware figures of Tanagra (Boeotia, central Greece) were first modeled by hand, then molds of whole figures were used, and finally the components—arms, legs, heads, and torsos—were all molded separately. The parts were often regarded as interchangeable, so that a variety of models could be constructed from a limited number of components. It is interesting to note that no improvement on this method of manufacture had been devised by the 18th century: the European porcelain factories made their figures in precisely the same way.

Plaster of paris molds were introduced into Staffordshire about 1745. They enabled vessels to be cast in slip, for when the slip was poured into the mold the plaster absorbed the water from it and thus deposited a layer of clay on the surface of the mold. When this layer had reached a sufficient strength and thickness, the surplus slip was poured off, the cast was removed and fired, and the mold was used again. This method is still in common use in the mid-20th century.

More recent methods of large-scale production are discussed in the section *Modern Manufacturing Techniques*, below.

5. Ceramic Figures.—Figures were made in ancient times, the most notable being those of Tanagra, mentioned above, and those of the T'ang dynasty of China. For the most part they were intended for religious purposes, particularly for placing in tombs as a substitute for the servants and cattle which earlier burial customs had demanded. In the 18th century A.D. figures became important again though this time they were used for purely ornamental purposes. The first serious attempt at modeling is a series of large animals from Meissen made for the Japanische Palais of Augustus the Strong. Small figures came into vogue as a result of the fashion for elaborate table decoration, which had hitherto been supplied by confectioners who worked in sugar. The most eminent of the modelers, and the man who secured for porcelain figures a popularity they have never lost, was J. J. Kändler of Meissen. Toward the mid-century all kinds of decorative ware were made in the form of figures and even practical articles such as candlesticks and vases were thus embellished. Today, such figures are sought by collectors as the chef-d'oeuvre of the factories responsible for them.

6. Decoration.—Even the earliest pottery is usually embellished in one way or another. The most primitive kind of decoration is that which is scratched into the raw clay with a pointed stick, chevrons being a particularly common motif. Finger marks are sometimes used, as well as impressions from rope, or from a "beater" bound with straw. The beater was used to shape the pot in conjunction with a pad held inside it. Basket and textile motifs have been mentioned above. Decoration which has been engraved after firing is much less usual, but the skilful and accomplished engraving on one fine Egyptian pot of the predynastic period (i.e., before c. 3100 B.C.) suggests that the practice may have been more frequent than was previously suspected.

The addition of separately modeled ornament, known as "applied" ornament, came somewhat later. The earliest known examples are found on Mediterranean pottery made at the beginning of the 1st millennium.

Painted designs are an early development, some remarkably fine

HAND-MODELED VESSELS

(Left) Polished red-ware, black-topped vase; Egypt, about 4000 B.C. Height: 21 in. (Above) Gray earthenware bowl; Nihavand, western Iran, about 2500 B.C. Height: 12½ in. In the Victoria and Albert Museum

matrix was consumed during firing, leaving the finished pot. It is not unusual to find imitations of the marks of a basket or textile weave incised as decoration into pottery made by other means.

Coiled pottery was the next development. Long strips of clay were coiled in a circle, layer upon layer, until the approximate shape had been attained and the walls of the vessel were then finished by scraping and smoothing. Some remarkably fine early pots were made in this way.

It is impossible to say when the potter's wheel was introduced. A pot cannot be made by hand modeling or coiling without the potter either turning it or moving round it and, as turning involves the least expenditure of human effort, it would obviously be preferred. The development of the "slow," or hand-turned, wheel as an adjunct to pottery manufacture led eventually to the

work made before 3000 B.C. coming from excavations at Ur and elsewhere in Mesopotamia, as well as urns from Pan-shan in Manchuria which date back to 2000 B.C.

Colour.—The earliest pottery colours appear to have been achieved by using slips stained with various metallic oxides. At first these were undoubtedly oxides which occurred naturally in the clay; later they were added from other sources. From early times right up to the 19th century, when pottery colours began to be manufactured on an industrial scale, the oxides commonly used were those of tin, cobalt, copper, iron, manganese, and antimony. Tin oxide supplied a useful white and was much used in making tin-enamel glaze (see *Types of Earthenware*, above). Cobalt blue is an extremely stable and reliable colour which yields similar results under both high- and low-temperature firings. For this reason it appears on pottery and porcelain alike and was used more than any other colour. Cupric oxide gives a distinctive series of blues, cuprous oxide a series of greens, and, in the presence of an excess of carbon monoxide, which the Chinese achieved by throwing wet wood into the kiln, cupric oxide yields a bluish red. This particular colour is known as "reduced" copper, and the kiln is said to have a "reducing" atmosphere. The colours obtained from ferric iron range from pale yellow to black, the most important being a slightly orange red, referred to as "iron red." Ferrous iron yields a green which can be seen at its best on Chinese celadon wares. Manganese gives colours varying from the bright red purple similar to permanganate of potash to a dark purplish brown which can be almost black. The aubergine purple of the Chinese was derived from this oxide. Antimony provides an excellent yellow.

Ceramic colours are used in two ways—under the glaze or over it. Earthenware and stoneware were usually decorated in underglaze colours. After the body was manipulated into the desired shape it was fired. It was then painted, dipped into, or sprayed with glaze and fired again. The second firing was at a lower temperature than the first, being just sufficient to fuse the glaze, the vitrification point of which may have been further lowered by the addition of certain substances known as fluxes. In the case of tin-enamelled wares the fired object was coated with the tin glaze and then painted, glaze and decoration being subsequently fired together. The painting needed exceptional skill since it was executed on the raw glaze and erasures were impossible. The addition of a lead glaze over the enamel needed a third firing.

The body and glaze of most hard porcelain were fired in one operation since the fusion temperature of body and glaze is roughly the same. Although the Chinese made some use of copper red, un-

derglaze painting is more or less limited to cobalt blue, since only this pigment will bear the full heat of the kiln satisfactorily. On soft porcelain, manganese was sometimes used under glaze, but examples are rare. All other porcelain colours were painted over the fired glaze and fixed by a second firing.

Underglaze pigments and those used with tin enamel are known as high-temperature colours, or colours of the *grand feu*. Similarly overglaze colours are known as low-temperature colours or colours of the *petit feu*. Other terms for overglaze colours are "enamel colours" and "muffle colours," the latter name being derived from the type of kiln, known as a muffle kiln, in which they are fired. Enamel colours consist of pigments mixed with glaze material suspended in a medium such as gum arabic, with an alkaline flux added to lower the melting point below that of the glaze. Enamel colours were used in Persia on pottery (*minai* painting) in the 12th century, and perhaps at the same date on Chinese stoneware made at Tz'u Chou. In the 18th century they were applied to European tin-enamelled wares, for example the *Fayence-Porcelaine* of Germany mentioned above.

A third method of applying colour to ceramics is to add colouring oxides to the glaze itself. Coloured glazes have been widely used on earthenware, stoneware, and porcelain and have led to the development of special techniques in which patterns were incised, or outlined with clay threads, so that differently coloured glazes could be used in the same design without intermingling, for example the *lakabi* wares of the Middle East.

Lustre decoration is carried out by applying a colloidal suspension of finely powdered gold, silver, platinum, or copper to the glazed and fired object. On a further, gentle, firing, gold yields a purplish colour, silver a pale straw colour, platinum retains its natural hue, and copper varies from lemonish yellow to gold and rich brown.

Lastly, ceramics may be gilded or silvered. The earliest gilding was done with gold mixed with an oil base. The use of gold ground in honey may be seen on the finest porcelain from Sévres during the 18th century, as well as on that from Chelsea. Toward the end of the same century gold was applied as an amalgam, the mercury subsequently being volatilized by heating. Silver was used occasionally for the same purposes as gold, but with time has nearly always turned black through oxidation.

7. Ceramic Marks.—Most porcelain and much earthenware bear marks or devices for the purpose of identification. Stonewares, apart from those of Wedgwood, are not so often marked. Ceramic marks are recorded in such standard works as W. Chaffers' *Marks and Monograms on Pottery and Porcelain* (1876, and many later editions) and W. B. Honey's *Dictionary of European Ceramic Art* (1952). Chinese porcelain marks usually record the dynasty and the name of an emperor, but great caution is necessary before accepting them at their face value. The Chinese frequently used the mark of an earlier reign as a sign of veneration for the products of antiquity, and, in recent times, for financial gain. Most books on Oriental porcelain include a list of the commonest marks.

The majority of European factories adopted a device—for example, the well-known crossed swords of Meissen taken from the electoral arms of Saxony, or the royal monogram on Sévres porcelain—but these, also, cannot be regarded as a guarantee of authenticity. Not only are false marks added to contemporary forgeries, but the smaller 18th-century factories often copied the marks of their more august competitors. If 18th-century European porcelain is signed with the artist's name it generally means that the painting was done outside the factory. Permission to sign factory work was rarely given, and usually it indicates a test piece, or something of the sort. Concealed signatures are sometimes to be noted.

On earthenware, a factory mark is much less usual than on porcelain. Workmen's marks of one kind or another are frequently to be seen, but signatures are rare. There are a few on Greek vases.

8. Forgeries.—Fine examples of pottery and porcelain have always commanded high prices in the salesrooms and this, in turn, has encouraged the making of forgeries and reproductions. Most

of these are not close enough to deceive a reasonably expert eye because until recently it has been impossible to procure materials in a pure state and potters used natural deposits whose impurities, for good or ill, often affected the final result. In all but a few isolated instances (some German stoneware reproductions, for example) the forger no longer has access to these original sources, and he has to imitate the effect of the impurities as best he may. Although the best forgeries are remarkably close to the originals, they are few in number, and the best safeguard against them is an acquaintance with genuine examples. Scientific methods of detecting forgeries are discussed in the next section.

9. Scientific Analysis.—Because of forgeries and the absence of documentation, physical and chemical tests are used to reinforce less exact methods of comparison and analogy generally used in assessing the date and provenance of doubtful specimens. Chemical analysis and examination under ultraviolet radiation are the two techniques most commonly employed, but analysis by X-ray spectroscopy, and testing for magnetic polarity, have also been used to a limited extent. Ultraviolet radiation is extremely useful for detecting restorations and repairs and for identifying certain types of wares.

Whether carried out by chemical means or by X-ray spectroscopy, analyses of unknown specimens are helpful only if they can be compared with analyses of objects which can be attributed with certainty. Since factories tended to draw raw materials from a well-tried source and having once evolved a satisfactory formula to go on using it, the compositions of the various types of ware are fairly consistent, although they show some minor variations.

The example which follows is a chemical analysis of early porcelain from Bow, in London: silica 55.1%, alumina 16.5%, quicklime 15.12%, magnesia 0.4%, iron oxide—a trace, phosphoric acid 11.5%, potash (potassium oxide) and soda (sodium oxide) 1.01%. This formula is recognizable immediately as 18th-century English soft porcelain containing bone ash. The bone ash is revealed by the high percentage of phosphoric acid, calcined bones yielding from 65 to 85% of basic calcium phosphate. The silica and alumina are both constituents of clay, about 50% of silica to 33% of alumina being average. Some glass contains silica, potash, and lime, the latter also being present in bone ash, while another variety of glass contains lead but omits the lime. Some early English soft porcelain of the glassy variety contains a considerable proportion of lead, the highest (about 17%) being found in a class which was perhaps made at Chelsea. In the Bow formula both magnesia and iron oxide are present accidentally. In Worcester porcelain, on the other hand, magnesia appears in great quantity (about 12% or more), indicating the presence of soap-rock, a kind of steatite. A true porcelain analysis should read somewhat as follows: silica 72.29%, alumina 19%, lime 0.1%, magnesia 0.53%, alkalis 4.46%, iron oxide 0.62%, 3% lost on ignition. Here the important ingredients are the silica and alumina contained in the clay and the fusible feldspathic rock. The other substances are present in fractional amounts with the exception of the alkalis. These may have been added to assist fusion, or they may have been present in the raw materials.

Examination by ultraviolet radiation ("black light") depends for its effectiveness on the phenomenon of fluorescence. The colour of any light depends upon its wavelength, violet light having the shortest wavelength of any visible light and red the longest. If the waves are extremely short, the light is no longer visible to the human eye, and is called "ultraviolet." Certain substances, however, possess the property of converting the invisible waves into visible light by lengthening the wavelength, and the object is then said to fluoresce. Fluorescence and phosphorescence are the same thing in principle, but the former disappears when the radiation which excited it has been shut off, whereas the latter persists for a while.

The usual source of ultraviolet radiation for ceramic investigations is a quartz tube filled with mercury vapour. This gives an intense visible illumination which is also rich in invisible ultraviolet radiation. The visible illumination is unwanted, and it is therefore screened off as far as possible by the interposition of a filter of suitably dyed glass. A little red and violet light passes

the filter, and the general appearance is of a subdued violet illumination.

It has been found that some specimens of old pottery and porcelain exhibit colours ranging from yellow to deep violet under ultraviolet radiation. Not all the effect is due to fluorescence. Some of it is a reflection of the red and violet light passing the filter, but this reflection also has peculiarities of its own which vary according to the nature of the glaze. In many cases the effect is reasonably characteristic of the material under examination. A certain class of Chelsea porcelain, for instance, invariably shows a distinctive peach colour, while other classes exhibit a violet colour which is mainly a reflection, but is also fairly distinctive. Because so much depends on an individual's reaction to colour the ultraviolet lamp is a very personal tool, and the results need to be interpreted in the light of the operator's experience. Restorations can always be detected immediately. The restored area almost invariably fluoresces with a brilliant yellow which stands out plainly from the unrestored porcelain glaze.

The other techniques mentioned are comparatively new but analysis by X-ray spectroscopy (*q.v.*) may, in time, replace chemical analysis, since the latter always means sacrificing part of what may be a valuable specimen. Some interesting work on Chinese porcelain utilizing X rays has been done in the United States by the Far Eastern Ceramic group. Magnetic polarity tests are applicable only to archaeological specimens.

10. Collections.—In the Far East both pottery and porcelain have always been treasured by collectors. When Chinese porcelain began to be exported in the 14th century, important collections were assembled in the Middle East, and later, from the 15th century onward, in Turkey, where a notable collection from this period still survives in Istanbul. In Europe the collecting of pottery and porcelain has been a pursuit of the leisured and wealthy classes since the early part of the 17th century, and latterly it has become more generally fashionable. Before 1600, although isolated examples of Chinese porcelain were regarded as among the treasures of kings and princes, there was little collecting in the modern sense. The fashion seems to have started with the appearance of Chinese and Japanese porcelain in larger quantities than hitherto. The first shipment of any size was brought into a Dutch port in the "San Jago," captured from the Portuguese, in 1602, and both Henry IV of France and James I of England bought part of the cargo. Soon the Dutch started to trade directly with China and were granted a monopoly of trade with Japan in 1641.

Cardinal Mazarin (1602–61), minister to Louis XIV, had a large collection of Chinese works of art which included porcelain, and Louis himself had a similar collection. Augustus the Strong (1670–1733) of Saxony and Poland spent 100,000 thalers (about £25,000) on porcelain in the first year of his reign alone, and is said to have exchanged a regiment of dragoons with Frederick I of Prussia for a set of Chinese vases. In the late 17th century a collection of Japanese porcelain brought to England by William III and Queen Mary II was lodged at Hampton Court. This made collecting fashionable in English court circles. During the middle years of the 18th century collections of Chinese porcelain and the products of Meissen and the royal factory at Sèvres were the vogue. Both Louis XV and Louis XVI were excellent salesmen of their factory's products, and Mme de Pompadour is reputed to have remarked that not to buy the porcelain of Sèvres was to prove oneself a bad citizen.

Until the French Revolution, however, most art collections were an assemblage of all kinds of rare and valuable objects which were more or less unrelated. A vast collection of this nature, much of it acquired from the sales of the royal French collections during the revolution, was gathered together by the English eccentric William Beckford of Fonthill Abbey near Salisbury. It was dispersed at an enormous sale in 1823.

Modern collectors tend to specialize in the wares of a certain period or country, and most of them do not include wares made later than the 18th century. Modern collecting dates, perhaps, from the days of Charles and Lady Charlotte Schreiber who, in the latter half of the 19th century, made a specialist collection of

English pottery and porcelain which is now in the Victoria and Albert Museum, London. Other important collections made since include Mortimer Schiff's collection of Italian *maiolica*, dispersed at the Parke-Bernet Galleries, New York, in 1946, and that of George Eumorfopoulos, who was mainly responsible for the fashion for early Chinese wares which prevailed in the 1920s. The latter is now in the British Museum, London. The important collection of Chinese porcelain formed by Sir Percival David is now housed in the Percival David Foundation in London. The collection of English porcelain made by Sigmund J. Katz, eventually to be housed in the Boston Museum of Fine Arts, will probably remain unsurpassed for its wealth of early wares, while that of Irwin Untermyer in New York is remarkable for a magnificent display of the finest work of Meissen, Chelsea, and other important factories, and an especially notable collection of German porcelain has been formed by Siegfried Ducret of Zurich. Early Japanese porcelain is probably best represented by the collection belonging to Gerald Reitlinger of Sussex, Eng., which is also rich in Persian pottery. The principle notable public collections include those of the Sèvres Museum on the outskirts of Paris, the Hetjens Museum (Düsseldorf), the Kunsthistorisches Museum (Vienna), the State Hermitage Museum (Leningrad), the Metropolitan Museum of Art (New York), the Smithsonian Institution (Washington, D.C.), Colonial Williamsburg (Va.), and the Victoria and Albert Museum and the British Museum (London).

II. HISTORY OF CERAMICS

A. FOREWORD

The pages which follow are a miniature, and therefore necessarily lacunary, history of the ceramic art of the world. Since every historical work must adopt a frame of reference, the subject is here discussed from the viewpoint of Europe and the United States. The section on the ceramic art of Asia not only provides information on the Far Eastern wares themselves but shows how strong has been the influence of the East on European potters. A preliminary reading of this section, therefore, ought to be undertaken by anyone seeking to understand the development of European wares from the early 17th century onward.

The first section of this history deals with the techniques of primitive pottery, the basis of all subsequent skills, many of which are found all over the world. The next section discusses the very early wares of Anatolia and the Near and Middle East. The first European pottery to be considered is that of the northern Mediterranean. Apart from some indebtedness to Egypt and Mesopotamia during the early part of the 1st millennium B.C., both form and motif are European. Most of the wares show a high degree of artistry and skill. After the decline of the Roman Empire, there was a long period in Europe in which pottery was unfashionable, metal being the preferred medium for table dishes and ornaments. Meanwhile in the Middle East from the 8th century A.D. onward there was a revival of the ceramic art, and it was the Islamic wares which reached Italy from Moorish Spain in the 14th century that eventually reawakened interest in Europe. In spite of this Moorish influence and the fact that the technique for glazing Italian *maiolica* was borrowed from the Middle East via Spain, ceramic styles during the Renaissance remained predominantly European.

From the beginning of the 17th century onward, however, Eastern influences grew progressively stronger. Toward the end of the 18th century, in the Neoclassical period, the styles of Greece and Rome returned to favour but the influence of China remained as firmly entrenched as before, and even today it is often to be noticed in modern commercial decorations. This is not surprising: ceramics have always been regarded as an important art form in most Eastern countries—in China, for example, they have a known and continuous history from about 1500 B.C.—and, until the last century, China has also been ahead of Europe in technical matters.

The pottery and porcelain of the Americas before 1800 is discussed in a separate section, below. American Indian pottery has no obvious relationship with that of any other part of the world and post-Columbian wares are mostly derived from those of Europe, partly because settlers brought with them the styles of

their own country and also because competition with European suppliers from the mid-18th century onward compelled the newly established factories to provide comparable wares. The article concludes with an account of modern manufacturing techniques.

It is possible to draw a fairly clear line between those wares made in the West before 1800 and those made afterward. The work of the 19th and 20th centuries is therefore discussed separately. The old tradition of craftsmanship, already weakened by the Industrial Revolution, hardly survived the Napoleonic Wars, and the growth of the factory system enforced the use of mechanical methods which, for many years, made it doubtful whether ceramics could survive as an art. Later years have seen a revival of the artistic traditions of this ancient craft, for example, by Bernard Leach and others, and the work of the larger factories has shown some improvement.

1. Importance of Ceramics in Historical Studies.—It is often desirable to identify the provenance and the date of manufacture of specimens of pottery and porcelain as closely as possible. Not only does such information add to the interest of the specimen in question and increase understanding of the ceramic art as a whole, but it often throws fresh light on historical questions or the social habits and technical skills of the time it was made. Since ceramics are not affected by any of the agents which attack metal, wood, or textiles, they are often found virtually unchanged after being buried for thousands of years while other artifacts from the same period are partially or completely destroyed. For this reason archaeologists use pottery extensively; for example, to trace contacts between peoples, since vessels were often widely distributed in course of trade, either by the people who made them, or by such maritime nations as the Phoenicians. Scientific methods of investigating ceramics have been discussed above.

2. Decorative Motifs.—The history of the ceramic art is much concerned with the origin of patterns, for decorative motifs from one place were freely adopted by others and once the source of a pattern is known both date and provenance of the copy can often be ascertained. Patterns were borrowed from countries with

which there was a trading connection, and the fact that they were borrowed at all perhaps suggests that those who supplied the inspiration were artistically in advance of those who took it. The copies were often free adaptations to which something of value was added, but many were done without understanding. Typical examples of the latter are the Moorish patterns on late Spanish lustre pottery, forms based on Arabic calligraphy which degenerated in the hands of Spanish workmen who neither spoke nor read Arabic. Much the same fate awaited the Chinese motifs copied by the European potters who transposed them to suit

DISH PAINTED IN BROWNISH LUSTRE PIGMENTS: VALENCIA, SPAIN, ABOUT 1430. DIAMETER: 21 IN. IN THE VICTORIA AND ALBERT MUSEUM

Western tastes and conventions and were ignorant of any symbolic meanings.

3. Provincial Wares.—The often considerable difference between wares made at a centre of manufacture where technical knowledge was advanced and contemporary, but rougher, wares from the provinces frequently tempts one to date the less well-finished specimen to an earlier period. Some of the provincial Chinese porcelain of the 18th century, for example, has been erroneously awarded an early Ming date. When pottery is excavated there are often other factors which enable the date to be estimated fairly closely, but isolated specimens often present difficult problems.

B. PRIMITIVE POTTERY

The methods of pottery making used by primitive peoples are very much alike, and there is little difference between the tech-

niques in use today and those of Neolithic times. However, comparatively little primitive pottery is being made in the mid-20th century, owing to improved communications and the opening up of vast tracts of land in Africa and elsewhere, and the interest of this section tends to be historical.

Pottery making is not universal. It is rarely found among nomadic tribes, since potters must live within reach of their raw materials. It has been absent from large regions of America, and in other parts of the world it is no longer practised. If there are gourds, skins, and similar natural materials which can be made into vessels without trouble, there is no incentive to make pottery.

Clay frequently needs to be "seasoned" before use; this is done by exposing it to the action of the weather. Clays which are excessively plastic crack and become distorted during drying and firing unless they are "opened" by mixing them with sand or some other material. Even chopped grass, animal dung, and cinders are used occasionally for this purpose, the last being found in some early British pottery.

Primitive methods of forming pottery vessels have been discussed in the introductory section *Methods of Fashioning Ceramics*, above. Generally speaking, the method most frequently used is coiling, although among a few primitive peoples baskets are still used as molds and sometimes the belly of the pot is shaped over a ring of vegetable fibre. The Hausa of Nigeria use an old pot as a mold by inverting it and then forming a sheet of clay over it in such a way that the mold can be withdrawn. Two or three sections shaped in this way may be joined to form a simple vessel. The neck and shoulders are then finished by hand. In some areas vessels are hand modeled from a ball of clay, the simplest method. Most primitive peoples can make excellent pots by these various means, and the wheel is rarely used. It is a more difficult tool, and needs long apprenticeship. An example of the achievements of the primitive potter without the wheel can be seen in the Chinese Neolithic urns from the Pan-shan cemetery in Manchuria.

The finished pot is first dried to "leather" hardness and then it is fired. Primitive "beehive" kilns have been observed in the lower Congo, but elsewhere the pots are simply stacked in a shallow depression or a hole in the ground and a pyre of wood is built over them. Charcoal is often used for firing.

Decoration is effected, more often than not, by incising lines into the raw clay with a pointed stick or with the thumbnail. The impression of rope can sometimes be seen; patterns of this kind occur on the Japanese Jōmon ware of the 1st millennium B.C. A more advanced technique was to use wooden stamps to impress the design, and in some places these were developed into rollers similar in principle to the Babylonian cylinder seal. Basketwork patterns are found on pots molded over baskets and are sometimes imitated on pots made by other methods.

Most designs are geometric, the chevron being particularly common, but animal, plant, and human forms appear occasionally on the more sophisticated wares. They are usually drawn in a stylized manner—which might be regarded as inevitable on primitive work were it not for the naturalism of some of the cave paintings executed at much earlier dates. Incised designs on a dark body are sometimes filled with lime which effectively accents the decoration. Examples can be seen in some early work from Cyprus and in some comparatively modern work from primitive tribes.

Applied ornament is unusual. When it does occur it is in the form of knobs, scrolls, or even crudely modeled figures. Raised designs are produced by pressing out the wall of the vessel from inside, a technique which resembles the *repoussé* method adopted by metalworkers.

The colour of the pot is dependent to a great extent on the composition of the body. Iron is almost ubiquitous in clay and under the usual firing conditions it oxydizes, giving a colour ranging from buff to dark red according to the amount present. In a reducing atmosphere (*i.e.*, one where a limited supply of air causes the presence of carbon monoxide) the iron gives a colour varying from grey to black, although a dark colour may also occur as a result of the action of smoke. Both of the colours which result from iron in the clay can be seen in the black-topped vases of predynastic Egypt. Slip was not commonly used among primitive peoples and painted decoration is extremely rare.

Glazing is an advanced technique which is not found in primitive pottery and its introduction is discussed later (see *China: Han Dynasty*, below). However, varnishes of one kind or another are often applied to overcome the porosity of low-fired earthenware. They are made from resins, gums, fat, or gelatinous substances. Varnished pots of this kind were made in Fiji, and specimens are not uncommon. When the clay is exceptionally fine, it is sometimes polished or burnished after firing, as in the case of the Pan-shan urns mentioned above.

Apart from vessels of various sorts—dishes, jars, vases, and the like—figures are made (often for some magical or votive purpose) and also tobacco pipes, drums, and other practical objects.

Primitive pottery making has usually been done by women, and in some cases men have even been prohibited from approaching while the operation was in progress. When the wheel was adopted, however, it became a male prerogative. The making of pots was often limited to certain families or to certain districts. The former practice was noticeable in China and Japan until recent times; the latter was probably due to the geographical location of the raw materials.

C. ANATOLIA, MESOPOTAMIA, AND EGYPT

It used to be thought that the first pottery came from the Middle East. However, in the early 1960s, excavations at a Neolithic settlement at Çatal Hüyük on the Anatolian Plateau of Turkey by James Mellaart revealed a variety of crude, soft earthenware estimated to be approximately 9000 years old. A more advanced variety of handmade pottery, hard-fired and burnished, has proved to be as early as 6500 B.C. The use of a red slip covering and molded ornament came a little later.

Sir Leonard Woolley found handmade pottery at Ur, in Mesopotamia, below the clay which he termed "the Flood deposit." Immediately above the Flood deposit, and therefore dating from a time soon after the Flood (about 3000 B.C.), was wheel-made, decorated pottery of a type usually called Al 'Ubaid after a nearby site which was the first to be cleared. Perhaps the most richly decorated pottery of the Middle East, remarkable for its fine

SUSQUEHANNOCK POTTERY JAR FROM CAYUGA COUNTY, NEW YORK. HEIGHT: 4 3/4 IN. IN THE MUSEUM OF THE AMERICAN INDIAN

painting, comes from Susa (Shushan) in southwest Iran. The motifs are partly geometric, partly stylized but easily recognizable representations of waterfowl and running dogs, usually in friezes. They are generally executed in dark colours on a light ground. Vases, bowls, bowls on feet, and goblets have been found, all dating from about 3200 B.C. By 3000 B.C. pottery is no longer decorated, but earthenware statuettes belong to this period, and a vessel (in the Louvre Museum, Paris) with a long spout based on a copper prototype is the ancestor of many much later variations on the same theme from this region in both pottery and metal. The body of this pottery contains a very large quantity of lime (37%), and it was fired at approximately 1000° C.

Remarkable glazed brick panels have been recovered from the ruins of Khorsabad (Dur-Sharrukin), Nimrud (Kalakh), Susa, and Babylon. They provide the first instance of the use of tin enamel, although the date of its introduction cannot be certainly determined. A well-known fragment from Nimrud in the British Museum belongs to about 890 B.C., and by the 5th century B.C. extremely large friezes, one of them about 11 yd. long, were being erected at Susa. The presence of lead in the blue glazes derived from copper suggests that the lead may have been added deliberately as a flux, and that this glazing technique, like that of tin enameling, was forgotten—to be recovered only at a much later date. In Egypt pottery was made in great variety in the predynastic period (up to c. 3100 B.C.), and a hard-fired ware of good quality was attained. Wares deteriorate in quality during the 1st dynasty (c. 3100–c. 2890 B.C.) but improve again by the 3rd (c. 2686–c. 2613 B.C.). The earliest forms of decoration were geometrical, or stylized, animal or scenic motifs painted in white slip on a red body. Comparatively little variation is to be noticed until the 26th dynasty (c. 664–525 B.C.), when clay was probably imported from Greece. Most artifacts are vessels of one kind or another, although pottery figures of variable quality were made, some of the later examples (after 500 B.C.) showing signs of Greek influence.

The so-called "faience" of Egypt is an unfired ware and thus, strictly speaking, falls outside our definition of pottery. It contained about 94% of sand, 2% of clay, soda and lime in varying proportions, and perhaps also an organic binder such as gum arabic. As early as the 1st dynasty, figures, vases, and tiles of this material were covered with a fired glaze (probably fused from powdered marble, soda, and sand) which was coloured turquoise and green with copper oxide. Later, the colouring materials common to the Egyptian glassmaker, including cobalt and manganese, were added.

D. THE AEGEAN AND GREECE

1. Neolithic Period (c. 6000–3000 B.C.).—The potter's art first reached the Aegean in the New Stone Age. All Neolithic vases are handmade and the best are highly polished: in other respects, the various local schools have little in common, since

communications were severely limited in this remote period. The main centres of ceramic production lay in Thessaly and Crete. Thessalian potters favoured a red monochrome ware but occasionally attempted simple painted decoration consisting of rectilinear patterns, with a vertical or diagonal emphasis. The Neolithic pottery of Crete is remarkable for its finely burnished surface, any decoration being usually incised.

2. Early Bronze Age (c. 3000–2000 B.C.).—On the mainland the ceramic initiative passed from Thessaly to the Peloponnese and Boeotia. The Early Helladic wares from these two areas show how quickly pottery fell under the influence of the new craft of metalworking: the two leading shapes, the "sauceboat" and the high-spouted jug, both have metal prototypes. Painted ornament is rare before the final stage (Early Helladic—usually represented by the initials "EH"—III); in the central phase (EH II) the surface is coated with a dark pigment formed from a solution of the clay. This type of paint, later much improved by the Athenians (see *Attic Black-Figure and Red-Figure*, below), remained the normal medium of decoration on all Aegean pottery until the adoption of a true silicate glaze in Byzantine times.

The contemporary wares of the Cyclades are similar, but more use is made of incised ornament: spirals are common motifs, while some vases bear primitive representations of ships. The pottery of Early Minoan Crete bears simple geometrical patterns, at first in dark paint on a light clay ground (EM I–II), and subsequently in white over a coat of dark paint (EM III). On the ware of Vasiliki in eastern Crete (EM II) a bichrome effect is obtained by placing the fuel up against the vase in the kiln so that the surface assumes a mottled red and black appearance. The commonest Early Minoan shapes are high-spouted jugs, and long-spouted drinking jars resembling teapots.

3. Middle Bronze Age (c. 2000–1580 B.C.).—After the conquest of the mainland by the first Greeks in the Middle Bronze Age the local schools of pottery developed on widely different lines. The Minyan ware introduced by the newcomers (named after the legendary Minyans of Orchomenos, where it was first found) is an unpainted monochrome fabric thrown on a fast wheel and fired in a reducing kiln to a uniform gray colour which penetrates right through the biscuit (the term generally applied to ware fired without a glaze); the surface is then highly polished and feels soapy to the touch. The shapes are all strongly carinated and probably derive from metalwork. The simultaneous appearance of Minyan pottery at Troy VI suggests that the Greek invaders arrived from a northeasterly direction. With them, too, had come the knowledge of the potter's wheel, already used at Troy II (2600–2300 B.C.).

Equally characteristic of this period are the matt-painted wares, which are mainly handmade: here rectilinear patterns are applied in dull black or lilac to a porous white surface. This fabric, although native to the Cyclades, was also widely imitated on the mainland; in the latest stage the ornament falls increasingly under the influence of the polychrome and curvilinear style of Middle Minoan Crete.

By far the most sophisticated pottery of this epoch was made in Crete, contemporarily with the first palaces at Knossos and Phaistos. The finest ware (Middle Minoan II) is confined to these two royal capitals together with the Kamares cave-sanctuary whence the style derives its name. Over a dark lustrous ground the ornament is added in red and white, the carefully composed designs striking a subtle balance between curvilinear abstract patterns and stylized motives derived from plant and marine life. The decoration sometimes takes the form of appliqué molded ornament, or barbotine knobs. By the time of MM II the use of the fast wheel had become general, imparting a new crispness to the profiles. Among the commonest shapes are carinated cups (often of eggshell thinness), small round jars with bridged spouts, and large storage jars (*pithoi*). In the course of MM III the fashion for polychrome schemes gradually died out, but at the very end of the period (MM III B) a new naturalistic style was born, inspired by the floral and marine frescoes on the walls of the second palaces. The wide distribution of MM pottery illustrates the vigour of Cretan commercial enterprise; several Minoan em-

(G. SE.)

poria were founded in the Aegean Islands, while exports also reached Cyprus, Egypt, and the Levant.

4. Late Bronze Age (c. 1580–1100 B.C.).—Aegean civilization now reached new heights of prosperity, displayed in the luxurious life of the Minoan palaces and the splendid treasures of the shaft graves at Mycenae. Potters were much influenced by work in richer and more spectacular media: many of their shapes can be traced to originals in gold and bronze found in Cretan palaces and Mycenaean tombs. Their decoration owes much to contemporary wall painting, although the motifs are always carefully adapted to the shape of the vase.

With the spread of Minoan culture round the shores of the Aegean, Cretan potters exercised a profound influence on the other local schools, and for the first two centuries of this period the vases of the mainland (known as Late Helladic or Mycenaean) are closely related to Minoan models. In the 16th century (LM I A) Cretan potters reversed their colour scheme, and returned to dark-on-light decoration. Their repertoire includes some abstract motifs (e.g., running spirals and vertical ripples) but is mainly derived from nature, a continuation of the figurative style of MM III B: flowers, grasses, and olive sprays are drawn with charm and spontaneity. After 1500 (LM I B) marine creatures are much in evidence, rendered with alarming realism: in a setting of coral and seaweed are often found argonauts, starfish, dolphins, and, above all, the octopus, wrapping his tentacles round the vase. However, on the palace style amphoras of the late 15th century (LM II) there is a reaction against this extreme naturalism: plants and marine life continue but in a more stylized and symmetrical form.

After the fall of Knossos in c. 1400 B.C., the artistic initiative passed to Mycenae and remained with it until the end of the Bronze Age. In the 14th and 13th centuries (LH III A and B) Mycenaean vases were widely exported, not only to Egypt and the Levant, but also as far west as Italy and Sicily. In the interests of commerce pottery was mass-produced, and the Mycenaean colonies on Rhodes and Cyprus were as prolific as the mainland. Some shapes, like the stirrup-vase, were imported for their contents of oil and unguents; others, such as the tall stemmed goblets, were prized for the excellence of their fabric. Yet in spite of their high technical standards, the decoration shows a strange lack of invention. In the absence of any new ideas, the old floral and marine motifs are subjected to an ever-increasing degree of stylization: the flowers degenerate into chevrons and dashes, the octopus into wavy lines. At the same time there is a new tendency to concentrate the decoration into a single focal zone, in anticipation of later Greek pottery. A few large jars bear crude representations of human figures in chariot scenes, probably derived from palace frescoes: no less schematic are the painted female figurines found in tombs and shrines of this period. In the pottery of the 12th century, which saw the collapse of Mycenaean civilization (LH III C), there is an abrupt decline in fabric as well as in artistic imagination.

5. Early Iron Age.—*Geometric Pottery* (c. 1100–c. 725 B.C.).—Pottery was the first art to recover its standards after the Dorian

invasion and the overthrow of Mycenae. Athens escaped these disasters and in the ensuing dark age became the chief source of ceramic ideas. For a short time Mycenaean motifs survived in debased form, but on new shapes. However, this "Submycenaean" ware soon gave place to the style known as Protogeometric (c. 1050–900 B.C.) by a natural process of evolution which converted the decaying Mycenaean ornament into regular geometrical patterns: thus the slovenly spirals were transformed into neat sets of concentric circles, always drawn with a compass fitted with a multiple brush. These circles are the hallmark of Protogeometric decoration which, like the latest Mycenaean, is confined to the handle zone; in the final stage the rest of the surface is covered with a thick black paint remarkable for its high lustre. Many shapes were inherited from Submycenaean, but all were tautened and vastly improved: the drinking vessels rest on high conical feet, while the closed vases have graceful ovoid bodies. After its invention in Attica the Protogeometric style spread to other parts of the Aegean world.

In the early 9th century Athenian potters introduced the full Geometric style by abandoning circular for rectilinear ornament, the key meander assuming the leading role. At first decoration is restricted to a small reserved area surrounded by the lustrous dark paint; later, as the style approaches maturity, more decorated zones are added until the potter achieves a harmonious balance between light and dark. In the 8th century, after nearly 400 years of abstract decoration, living creatures appear once again, although their style is hardly less angular than the geometric ornament that supports them. Geometric pottery reached its fullest development in the gigantic amphoras and kraters that served as grave monuments in the Athenian Dipylon cemetery; here a funerary scene, showing the corpse on the bier surrounded by mourners, occupies the main panel, while other friezes contain chariot processions, battles on land and sea, rows of animals, and linear geometric designs. The creators of these monumental vases established a continuous tradition of figured painting which persisted on Greek pottery until the end of the classical period; the immediate consequence of their innovation was a loss of interest in purely abstract design, which became increasingly perfunctory on the latest Geometric vases.

6. Period of Oriental Influence (c. 725–c. 600 B.C.).—After several centuries of isolation, the renewal of contact with the Near East provided a welcome stimulus to the Greek potter. In art, as well as in commerce, it was Corinth who now led the way. Unlike the Athenians, her potters specialized in small vases and especially in the tiny aryballos, or scent bottle, which found a ready market all round the Mediterranean. Hence arose the miniature style called Proto-Corinthian, which borrowed much of its repertoire from the fauna and flora of Syro-Phoenician art. Processions of animals, both real and legendary, are placed in the main friezes, while lotus flowers and palmettes serve as subsidiary ornament. When human beings appear, mythical scenes can often be recognized, reflecting the early diffusion of Homeric epic poetry. It was on Proto-Corinthian vases that the technique known as "black-figure" was first applied: the figures are first drawn in black silhouette and are then marked with incised detail; further touches are added in purple and white. The pottery of Corinth reached the peak of its excellence in the middle of the 7th century; later, in the course of the Ripe Corinthian style (c. 625–550), quality is sacrificed in the interests of mass production.

Other notable "Orientalizing" styles arose in Attica ("Proto-Attic"), the Cyclades, Laconia, and Rhodes, regional differences in pottery becoming more clearly marked as the Hellenic city-states grew into self-conscious political units. The Athenians still did their best work on large funerary vases. At first they cultivated a wild and grandiose manner in which the figures of men and animals were elaborated in outline; later the idea of incised ornament was introduced from Corinth, and imposed a salutary discipline. Cycladic potters also attempted the grand manner; Laconian work, on the other hand, is confined to a small scale, and owes comparatively little to Oriental influence. The Rhodians rarely progressed beyond animal friezes drawn in outline; their style is known as "wild goat," after their favourite

quadruped. Each of these local schools could match the vitality of Proto-Corinthian drawing, but none could excel its purity of line.

7. Attic Black-Figure and Red-Figure.—Archaic Period (c. 600–c. 480 B.C.).—By c. 550 B.C. Athens had once again become the principal centre of pottery manufacture in Greece, having ousted its Corinthian rivals from the overseas markets. Its success is at least partially due to a sudden improvement in fabric, for its potters had by now learned how to obtain the familiar orange-red surface of their vases by mixing a proportion of ruddle, or red ochre, with their clay. The Corinthians tried to imitate this Attic colour by adding an orange slip to their pale yellow clay, but in vain. As the main medium of decoration, the Athenians perfected a shiny black pigment that was more lustrous than anything that had been achieved hitherto. The nature of this black pigment has been much disputed, and it has been variously described as a "glaze" and as a "varnish." Technically, it is neither. It lacks the glossiness and vitreous nature of a true glaze, while the fact that it was fired makes it unlike a varnish. Research by Theodor Schumann in the 1940s has shown it was achieved by painting the vase with a mixture of an iron-containing clay (such as was commonly found in Attica) and potash. Sour wine or urine was added to the mixture to prevent it from running during firing, and when the pot was fired in a reducing atmosphere a glossy black surface appeared, due to the formation of ferrous oxide.

In these centuries most of the more important vases were painted either in the black-figure, or in the slightly later red-figure technique, so that some explanation of the essential difference is necessary. Perhaps the closest analogy is to say that the two classes resemble a photographic negative and a print, the black-figure style being the negative. Such figures were painted in the glossy black pigment on the orange-red polished surface, appearing in silhouette; details, as mentioned above, were indicated by incised lines, and by the occasional use of white and purple, the female figure, especially, being painted in white. Decoration on the red-figure vases was first outlined in black; the remaining surface was then completely covered by the black pigment, leaving the figures reserved in red. Details were added in black, and in dilutions of the black pigment which appear as brown; purple is occasionally found at first, but dies out in mature red-figure work. The use of white is revived on the gaudier vases of the 4th century, where yellow brown, gold, and even blue, are sometimes used.

The Attic black-figure style was well developed by the beginning of the 6th century. Among the most favoured subjects were the labours of Hercules and Theseus and the revels of Dionysus with his attendant train of satyrs and maenads. The practice of signing vases, already begun in the 7th century, now became more common. The signatures, always in black paint, record either the potter or the painter, or in some cases both. The inscription on the celebrated François vase in the Museo Archeologico in Florence ("Ergotimos made me; Kleitias painted me") supplies our first positive evidence that the two functions had become sepa-

Exekias the possibilities of black-figure were virtually exhausted, and after the invention of red-figure (c. 530 B.C.) it is not surprising that the best artists soon turned to this new technique, which allowed a greater freedom of expression, and a more naturalistic treatment of the human frame. After c. 500 B.C. the only important vases in black-figure are the amphorae presented to victors at the Panathenaic Festival; these have a figure of Athena standing between two pillars, and are usually inscribed "I am one of the prizes from Athens."

The early red-figure artists were not slow to exploit the advantages of the new system. Benefiting from the experience of relief sculptors, they had mastered the problems of foreshortening by the end of the 6th century; but since they still avoided any suggestion of depth in their grouping, they were able to convey the illusion of a third dimension without doing violence to the two-dimensional surface of the vase. The most successful work was done in the final years of the Archaic period (c. 500–c. 480 B.C.) when the style of the figures, with their formal and elaborate patterns of drapery, was still decorative rather than naturalistic. Monotony was avoided

FIG. 1-14.—ATTIC BLACK- AND RED-FIGURE FORMS

(1) *Amphora*: two-handled jar for storing liquids. Those with a pointed base are designed to stand in sand. (2) *Hydria*: three-handled jar for carrying water. (3) *Stamos*: wine jar. (4) *Bell krater*: large bowl for mixing wine and water; the bell krater is confined to red-figure. (5) *Psykter*: wine cooler. (6) *Lebes*: cauldron, sometimes provided with a stand, as here. (7) *Volute krater*: large bowl for mixing wine and water; named for its handles. It is found throughout the black- and red-figure styles. (8) *Lekythos*: oil flask, often used for funerary purposes. (9) *Kantharos*: drinking cup with two high vertical handles. (10) *Skyphos*: drinking bowl with two horizontal handles. (11) *Aryballos*: small unguent bottle. (12) *Kylix*: shallow drinking cup, usually provided with a pedestaled foot. (13) *Oinochoe*: wine jug with a trefoil lip, revived during the Renaissance and in the 18th-century neoclassical period. (14) *Alabastron*: small unguent bottle with rounded base

red-figure, Greek pottery is undistinguished. Painted decoration is virtually limited to festoons of ivy, laurel, and vine in white or yellow over a black ground; the black pigment loses its lustrous sheen, and assumes a dull metallic texture. A class of hemispherical bowls, known as "Megarian," was made in molds, and bears relief decoration in imitation of metal bowls. Altogether more remarkable are the contemporary terra-cotta figurines; among the most accomplished are the draped women from Tanagra in Boeotia, whose artistic value is sometimes marred by excessive sentimentality. (J. N. Co.)

E. ITALY

At the beginning of the Iron Age the pottery of the Villanovan culture was incised with rectilinear patterns somewhat reminiscent of Geometric Greece; the resemblance, however, is fortuitous, since there is no trace of Greek contact with Italy at this time (c. 900 B.C.). The most characteristic vessel is the cremation urn; this is usually biconical in shape, but sometimes takes the form of a primitive hut, decorated with quasi-architectural ornament in relief.

1. Etruria.—The first pottery of importance is the black Etruscan ware called *bucchero* which, like Middle Helladic Minyan (see above), was fired in a reducing

kiln. The earliest examples of the 8th century B.C., for which the wheel was rarely used, were decorated with incised or engraved ornament in the form of geometric patterns. By the 6th century lively and stylized birds and animals were engraved, modeled, or applied, in conjunction with such geometric patterns as reentrant spirals, or in friezes. Later relief ornament was often executed by rolling a cylinder with design recessed in intaglio over the soft clay, the principle being the same as that used to make Babylonian cylinder seals. Vases with covers in the form of a human head, with arms slipped through fixed ring handles, were made for funerary purposes until about the mid-6th century.

In the late Archaic period the Etruscans excelled in life-size terra-cotta sculptures, of which the outstanding examples are the menacing figure of Apollo, from his temple at Veii, and the large sarcophagi from Caere with couples of banqueters reclining on the lid. Some large figures of warriors have since been recognized as forgeries, and at least one forged sarcophagus is in existence. Figures, heads, and busts continued to be made in the Hellenistic period.

2. Greek Influence.—Proto-Corinthian ware was copied with great exactness by Greek colonists as early as 700 B.C. at Cumae, near Naples. The Etruscans soon learned to use the Greek black pigment, and stylized human and animal figures appear in red, black, and white on a light clay or on the *bucchero* surface. Copies of the black-figure vases were soon so accomplished that it is not always easy to tell exactly where a specimen was made. The red-figure class, however, is rarely difficult to separate from Greek work. The decoration is much more flamboyant and elaborate, and the reverse is often carelessly executed. Many Greek vases were imported and used for funerary purposes. These have fre-

through the use of a wide variety of poses and simple devices for rendering character and mood. At the same time the repertoire of subjects was greatly enlarged; besides the old heroic and Dionysiac themes, many scenes from daily life (especially riotous banquets) now took their place.

The Classical Period (c. 480–c. 330 B.C.) saw a progressive decline in Attic vase painting. Owing to the very limitations imposed by the pot surface, the vase painter could no longer keep pace with the rapid advance toward naturalism in the major arts, and the occasional attempts at perspective and depth of grouping simply detracted from the shape of the vessel (a mistake repeated in some painting on Italian *maiolica* in the late 16th century A.D.). Furthermore, much of the later Attic vase painting shows a saccharin sentimentality and triviality of thought in both the choice of subject and its treatment which is much at variance with the earlier wares. But here we must admit a distinguished exception in the funerary *lekythoi* of the late 5th century, decorated in subdued matt colours on a white background. The figures on these vases, isolated and statuesque, share the serenity and restraint of the Parthenon sculptures and allow us to visualize something of the grandeur of classical free painting, nearly all of which is now lost. In the 4th century the figured decoration of pottery had become a degenerate art and it had died out in Attica by c. 320 B.C.

In addition to their black- and red-figure vases, the Athenians manufactured plain black-painted wares in great quantity; these follow the shapes of the figured pottery. There was also a limited vogue for plastic vases, in the shape of human or animal heads, which sometimes bear painted decoration in the style of the period.

3. Hellenistic Period (c. 330–c. 30 B.C.).—After the end of

quently been recovered intact, or almost so, from Etruscan tombs.

Long after the red-figure style had fallen into disuse in Greece it lingered on in Italy, particularly in the south. Those specimens most usually seen came from Lucania, Apulia, Campania, or Paestum. Campanian and Apulian vases are especially apt to be profusely decorated. Black ware decorated in relief, and based on metal vases, was made from about the 3rd century onward.

3. Roman Empire.—The characteristic, and most widely dispersed, type of pottery was the red, polished Arretine ware, so-called because manufacture was at first concentrated at Arretium (modern Arezzo). It is sometimes also misleadingly termed "Samian ware," from a supposed connection with the island of Samos. The body was generally formed in a mold and was frequently decorated with raised designs. These were achieved by using a mold which had itself been impressed with several stamps arranged in the desired pattern. This decorative technique—which gave to the ware yet another name, "*terra sigillata*" ("clay

later European ceramics has been profound.

The earliest Chinese pottery is of the Neolithic period and has been discovered in the provinces of Honan and Kansu; it may not be without significance that Kansu is the traditional overland gateway to China from the west since the decoration especially exhibits affinities with wares found as far west as the "Black Earth" region of the Ukraine. Perhaps the best known of these wares is a series of large urns of red polished pottery with geometric decoration found both in the Pan-shan cemetery and at Ma-ch'ang, both in Kansu Province. These were made by hand, the latest specimens with perhaps some assistance from a "slow" wheel, and are at least as early as 2000 B.C.

1. Shang (or Yin) and Chou Dynasties (c. 1766–256 B.C.).—Fragments of a fine white stoneware dating from about 1400 B.C. have been found at An-yang (Honan). The only known complete specimen—in the Freer Gallery of Art in Washington, D.C.—is decorated with chevrons (linked "V"-shapes) and a key-fret pattern, the shoulder motifs being reminiscent of those to be seen on contemporary bronze vessels. This ware is much better in quality than most other surviving pottery of the Shang period (c. 1766–c. 1123 B.C.) or of the following Chou dynasty (c. 1122–256 B.C.). Much Chou pottery is decorated with rudimentary incised ornament, some of which resembles the impress of coarse textiles and is referred to as "mat markings." The shapes were often inspired by bronze vessels.

The development of glazing in China may have started with the application of glass paste to some of the later Chou wares. Stoneware vessels of about the 3rd century B.C. have a glaze which is little more than a smear, but which has obviously been deliberately applied. This type persisted for several centuries. R. L. Hobson in *Chinese Pottery and Porcelain* (see *Bibliography*) has suggested that glaze may originally have been discovered by accident as a result of wood ash coming into contact with the surface of the pot during firing; the potash in the wood ash would then act as a flux forming a glaze from the silica in the clay. This explanation is likely enough.

2. Han Dynasty (202 B.C.–A.D. 221)—The first pottery to survive in appreciable quantities belongs to the Han dynasty and most of it has been excavated from graves. Perhaps the commonest form is the *hu*, a baluster-shaped vase copied from bronze vessels of the same name, and sometimes decorated with relief ornament in friezes taken directly from a bronze original (see *METALWORK, DECORATIVE*). The "hill" jar, which has a cover molded to represent the Taoist "Isles of the Blest," is another fairly frequent form and many models of servants, domestic animals, buildings, wellheads, dovecots, and the like also have been discovered in graves. Some of this pottery is unglazed, or decorated with cold (i.e., unfired) pigments, but much of it is covered with a glaze which varies from copper green to yellowish brown which has often become iridescent during its long burial. The body is usually a dark red and approaches stoneware in hardness.

Han glaze is more glasslike than that of the Chou period and is of an excellent quality, obviously carefully regulated. It contains lead and was frequently coloured green with copper oxide. It has been suggested that it was introduced from western Asia, and was ultimately derived from the Roman green glazed pottery mentioned in the preceding section; at the time, there were well-established contacts with Rome where Chinese silk, under the name of Coan silk, was especially valued. On the other hand, it is now recognized that glass was made in China much earlier than was once thought—slightly before the Han period in fact—and glazes of this kind may have developed independently.

Celadon.—Yüeh yao ("ware") was first made at Yüeh-chou in Chekiang Province during the Han dynasty, although all surviving specimens are later. These have a stoneware body and an olive or brownish-green glaze and belong to the family of celadons, a term which looms large in any discussion of early Chinese wares. It is applied to glazes ranging from the olive of Yüeh to the deep green seen on later varieties. These colours were due to a wash of slip containing a high proportion of iron which was put over the body before glazing. The iron interacted with the glaze during firing and coloured it.

ITALIAN POTTERY

(Left) Etruscan amphora of bucchero ware decorated with a frieze of horsemen in relief; 6th century B.C. Height: 20½ in. (Above) Roman bowl of Arretine ware with a design of the seasons in relief. Made in the factory of Cn. Ateius in about 10 B.C. Height: 7½ in. In the British Museum

impressed with designs")—was borrowed from metalwork. The patterns also were often influenced by metalwork and include floral and foliate motifs, mythological scenes, and scenes from daily life. The potteries at Arretium, which were organized on factory lines, operated between about 30 B.C. and A.D. 30, their products being highly prized and widely exported. Wares were stamped with the name of the potter and, probably for the first time, the name of his employer. Manufacture in Italy seems to have ceased very suddenly and was taken up, in the 1st century A.D., in southern and then in central Gaul. At first Gaulish pots resemble those of Arretium; later the body becomes rougher, the designs less disciplined, and trailed slip was sometimes added as decoration. From the 2nd to the 6th centuries the ware was also made in the eastern Mediterranean and North Africa.

Lead glazing perhaps originated or was rediscovered (the Assyrians having used it) in Egypt. Certainly it was established in the Near East by the 1st century B.C. The glazes were generally stained with copper to yield a greenish colour, and were used over relief decoration which, like the designs on Arretine ware, betrays the influence of metalwork. The technique had reached Italy and France by the 1st century A.D.

Of the other varieties of Roman pottery, lamps made either in a buff or a dark gray clay are exceptionally common, and usually have an impressed or molded design. A few depicting Christian motifs or gladiatorial combats were prized a little more highly than most specimens, but, generally, they are of little value, monetarily or otherwise. Molded terra-cotta plaques with reliefs of mythological and other subjects borrowed from Greece were often used to decorate buildings.

F. CHINA

Nowhere in the world have pottery and porcelain assumed such importance as in China, and the influence of Chinese porcelain on

CHINESE CERAMICS OF THE HAN AND T'ANG DYNASTIES

(Left) Watchtower with pale green glaze; Han dynasty (202 B.C.—A.D. 221). Height: about 25½ in. (Right) Lady and a phoenix headdress; T'ang dynasty (A.D. 618–906). Height: about 17½ in. In the Museum of Fine Arts, Boston

3. Six Dynasties (A.D. 221–589).—Most Yüeh ware belongs to the Six dynasties, a period of strife about which little is definitely known. To the same period belong some tomb figures, often in a dark grey body with traces of unfired pigment. The Han green glaze was also still in use.

4. T'ang Dynasty (A.D. 618–906).—Chinese ceramics reach an important stage in their development during the T'ang dynasty. Nearly everything which has survived has been excavated from tombs, many of them found accidentally by railway engineers and latterly by more systematic excavations. Perhaps the most important single development was the use of coloured glazes, either as monochromes, or splashed and dappled.

The influence of Persian metalwork of the Sassanid period (3rd–7th centuries) is seen in some of the shapes used and in the occasional use of engraved decoration. Greek influence can also be traced in some examples of T'ang pottery; it reached China by way of the province of Bactria (Balkh) in Afghanistan, and was the delayed result of the conquests of Alexander the Great in the Middle East.

Excavations at Samarra on the Tigris, a pleasure resort built by the caliph al-Mu'tasim (son of Harun al-Rashid) in A.D. 838, have uncovered many fragments of T'ang wares of all kinds. Since Samarra was more or less abandoned in 883, wares found on this site can be dated with a certain amount of confidence. Perhaps the most important finds from a historical viewpoint are the fragments of what is undoubtedly porcelain. An Islamic record of travels in the Far East, written in 851 and attributed to Ibn Wahab, records "vessels of clay as transparent as glass." There can be little doubt, therefore, that translucent porcelain was made in the T'ang period, although it was not until the Yüan dynasty (1280–1368) that it began to resemble the type with which we are now most familiar.

The T'ang wares commonest in Western collections have a highly absorbent, buff, earthenware body, and are covered either with monochrome or dappled glazes. The latter were usually applied with a sponge and include blue, dark blue, green, yellow, orange, straw, and brown colours. These glazes normally exhibit a fine crackle, and often fall short of the base in an uneven wavy line, the unglazed surface area varying from about one-third to two-thirds of the vessel. Dappled glazes are also found on the magnificent series of tomb figures with which this period is particularly associated. Similar figures were made in unglazed earthenware,

and were sometimes decorated with cold pigment.

Although the unglazed specimens, or those covered only with the straw-coloured glaze, are occasionally modeled superbly, many are crude and apparently made for the tombs of the less affluent and influential. Most of the glazed figures are much better in quality, and occasionally reach a large size; figures of the Bactrian camel, for instance, are particularly impressive, some being nearly three feet high. The Bactrian pony, introduced into China about 138 B.C., is to be found in many spirited poses. The fashion for tomb figures fell into disuse at the beginning of the Sung dynasty (A.D. 960–1279), but was revived for a short while during the Ming period (1368–1644) when T'ang influence is noticeable.

"Marbled" wares are seen occasionally. The effect was achieved either by "combing" slips of contrasting colours (*i.e.*, mingling the slips after they had been put on the pot, by means of a comb), or by mingling differently coloured clays. Another type of T'ang ware had a stoneware body with a dark brown glaze streaked by pale blue. It probably came from Honan. A few wares known from literary references, of which Ch'ai yao is an example, still remain unidentified.

Most vessels stand on a flat base and although later T'ang wares sometimes were given a footring, for the most part this can be regarded as evidence in favour of a Sung dating. At this point it is worth remarking that many Chinese ceramics cannot be dated with certainty since there were traditional and persisting types which overlapped and, quite often, these dynastic labels cannot be regarded as more than an indication of the affinities of the object under discussion.

5. Sung Dynasty (A.D. 960–1279).—The wares of the Sung dynasty are those most highly regarded by Chinese and Japanese connoisseurs, and by many in the West. They are particularly noted for brilliant feldspathic glazes over a stoneware body, and their emphasis on beauty of form. Decoration is infrequent but may be incised, molded, impressed, or carved; a certain amount of painted decoration was done at Tz'u Chou in Chihli (now called Hopeh) Province (*see below*). The esteem accorded to the Sung wares accounts for the relatively large number which have survived. Literary references, too, are greater in number and more exact than previously, although the habit of referring to vessels in poetic language sometimes makes identification with existing specimens difficult. The principal varieties are Ju, Kuan, Ko, Ting, Lung Ch'üan, Chün, Chien, Tz'u Chou, and *ying ch'ing*.

Ju yao has a buff stoneware body and is covered with a dense greenish-blue glaze which sometimes has a fine crackle. It was made in Honan at an imperial factory which apparently had a

life of about 20 years, starting in 1107. For years it was known only from literary references, and it was, at one time, tentatively identified with *ying ch'ing* ware (see below). The reader is referred to "A Commentary on Ju Ware" by Sir Percival David in *Transactions of the Oriental Ceramic Society, 1936-1937*.

Kuan is another imperial ware which is also exceedingly scarce. The name means "official." It was probably first made in the north, the kilns being reestablished at Hangchow in Chekiang Province about 1127 when the court fled southward to escape the Chin Tatar invaders. The body is of stoneware washed with brown slip while the glaze varies from pale green to a lavender blue with a wide-meshed crackle emphasized by the application of brown pigment. Chinese references to "a brown mouth and an iron foot" can be identified with the colour of the rim and the footring.

Ko yao is closely related to *Kuan* ware. It has a dark stoneware body and a grayish-white glaze with a well-marked crackle, which was induced deliberately for its decorative effect and is well controlled. *Ko* ware was extensively copied in the 18th century in a porcelain body.

Ting wares are white in colour. Some exhibit an orange translucency, while the coarser varieties are opaque. The finest examples are called *pai Ting* ("white" Ting). On the exterior of bowls and similar vessels *pai Ting* glaze is apt to collect in drops, called "teardrops." Many articles, particularly bowls, were fired mouth downward, leaving an unglazed rim which was afterward bound with a band of copper or silver. (Bands appear occasionally on other Sung wares, notably *ying ch'ing*, and were sometimes used to conceal damage rather than an unglazed rim.) Coarser varieties are known as *fen Ting* ("flour" Ting) and *t'u Ting* ("earthen" Ting), and there are also references to brown, black, and red Ting, although only a few examples of black Ting now survive and the others have not been identified. As in the case of *Kuan yao*, the kilns are said to have been removed southward in 1127, but it has so far proved impossible to differentiate between the northern and southern varieties. Other white wares made elsewhere during the period include those of Tz'u Chou, and a variety covered with a white slip over a grayish body from Chü-lu Hsien, both in Chihli Province.

Lung Ch'üan. The celadons of Lung Ch'üan are, perhaps, the most common of the classic Sung wares. The town is in the province of Chekiang, near the capital of the southern Sung emperors at Hangchow. The kilns probably date back to the 10th century. The glaze, which is superb in quality, is a transparent green in colour. It is thick and viscous, usually with a well-marked crackle. The glaze on early specimens is less transparent and more dense. The body is gray to grayish white, best seen at the rim where the glaze tends to be thin, and unglazed parts burned to a dark brownish red. A bluish-green variety of celadon is sometimes called *kinuta seiji*, a Japanese term meaning "mallet" celadon. It is applied to a favourite shape which resembles a fuller's mallet, the colour of which is much prized in Japan. Another variety, *tobi seiji*, has isolated spots of brown in the green glaze. By far the most frequent surviving examples of Lung Ch'üan celadon are large dishes for which there was a thriving export trade, due in part to the superstition that a celadon dish would break or change colour if poisoned food were put into it. Bowls and large vases, both of which are scarce, were also made with this glaze. Decoration is usually incised but molded decoration is also found. On some pots the molding was left unglazed so that it burned to a dark reddish brown—an effective contrast to the colour of the glaze. The more finely potted wares are the scarcest, and often the oldest. The heavier varieties were intended to withstand the rigours of transport to overseas markets and probably most of them belong to the following Yüan dynasty (1280-1368), when the export trade was considerably extended.

Of the other celadons of the period, it is desirable to mention the northern group. These have an olive-green glaze, and the decoration is carved or molded, usually with foliate motifs. Their relationship to Yüeh yao (see *Han Dynasty*, above) is fairly obvious, but there are a number of differences. Most Yüeh specimens, for instance, show signs of having rested on little piles of sand in the kiln, whereas this feature is absent from northern

celadons. Tung yao, known from Chinese literary sources, may be related to this group.

The kilns of Lung Ch'üan were transferred to Ch'ü-chou not far away at the beginning of the Ming dynasty (1368-1644). The suggestion that an unglazed band inside the footring may be a sign of Ch'ü-chou manufacture is not an entirely trustworthy one.

The celadon glaze was used at Kingtechen (Ching-te-chen), in Kiangsi (Chiang-hsi Sheng) Province, over a white porcelain body from the Ming period onward, and at the kilns in Kwangtung Province over a dark stoneware body during the same period. Figures of Kuanyin (Bodhisattva of Compassion) in a shrine are usually of Kwangtung manufacture.

Chün ware is more popular with Western collectors than it is in China. It comes from the K'ai-feng Fu District of Honan Province, and the body is a grayish-white hard-fired stoneware covered

with a thick, dense, lavender blue glaze which is often suffused with crimson purple. This is the first example of a reduced copper, or *flambé*, glaze (which is also known as a "transmutation" glaze, the more familiar colours derived from copper being blues and greens). Conical bowls are especially numerous, and dishes not unusual, but the finer specimens are usually flowerpots, sometimes said to have been made for Imperial use. Characteristic are barely perceptible channels or tracks caused by the parting of the viscous glaze; these are called "earthworm tracks" by the Chinese. The

DISH OF CHÜN WARE; SUNG DYNASTY (A.D. 960-1279). DIAMETER: 7 3/4 IN. IN THE VICTORIA AND ALBERT MUSEUM

kilns probably continued to produce this ware until the 16th century, and it is difficult to separate some of the later productions from the earlier. Imitations are numerous, some fairly close approximations being made in a white porcelain body in the reign of Yung Cheng (1723-35). The footring was washed over with brown to simulate that of the earlier ware. The impressed seal of the reign was sometimes added, but has frequently been ground out later by someone anxious to pass the vessel off as being made in the Sung period. "Soft Chün" has a dense, opaque, glaze which is markedly turquoise in colour. Most of it belongs to the Ming period, although isolated specimens may be earlier. "Fat-shan" Chün, which is not a particularly good imitation, was made in the Canton area.

Chien-yao is called after the original place of manufacture. Chien-an, in Fukien Province. Manufacture was later moved to Chien-yang nearby, probably during the Yüan period. The glaze is very dark brown, approaching black, over a dark stoneware body, and it usually stops short of the base in a thick treacly roll.

Many variations in the colour of the glaze are to be observed. Streaks in lighter brown are referred to by the Chinese as "hare's fur." Silvery spots on the glaze are called "oil spots." The most usual surviving form is the teabowl; these were much esteemed by the Japanese under the name of *temmoku* and were later used in the Tea Ceremony. The black glaze was imitated in Honan Province where the glazes were used on a variety of wares.

Tz'u Chou. The kilns of Tz'u Chou are now in Hopeh Province, although they were formerly in Honan. The earliest surviving examples are referable to the T'ang dynasty and the kilns were still working in the 1960s. The finer varieties of this ware are sought by Western collectors and have inspired a certain amount of modern English studio pottery but, generally, they have not been esteemed very greatly in China. In the Sung period vases, wine jars, and pillows were the most usual products. The body is usually a hard-fired grayish-white stoneware which was first covered with a wash of white slip and then with a transparent glaze. For the first time painted decoration appears under the glaze, perhaps as a result of influence from the Middle East. Decoration is nearly always in brown or black; the motifs are usually floral and

display a singular freedom of line which is very attractive. (The inclusion of human and animal figures suggests a Yüan or a Ming dating, at the least.) The slip covering was sometimes carved away leaving a pattern in contrasting colour, a technique also used in conjunction with a dark brown glaze. A "hare's fur" glaze, similar to that of Chien wares, was also employed. A blue glaze with painted decoration in black beneath it was obviously inspired by contemporary Persian pottery decorated in the same way. Another innovation, perhaps derived from the same source, is the use of enamel colours applied over the glaze. These are limited to primitive reds and greens and yellows. The dating of Tz'u Chou wares is frequently difficult, and depends principally upon style.

Ying ch'ing. An important and not uncommon ware is *ying ch'ing* ("shadowy blue"). However, little is definitely known about it as there seem to be no contemporary references to it, a strange lacuna considering its wide distribution. It was manufactured both in the south (Kiangsi) and the north (Hopeh). Moreover, it was extensively exported, and has been found as far west as the ruins of Al Fustat (Old Cairo). The body is pale buff in colour, usually translucent, and thinly potted, breaking with a sugary fracture. Most genuine examples seem to belong to the Sung and Yüan periods, but it is probable that, at any rate in the north, manufacture started late in the T'ang dynasty, and lasted well into the Ming period. Bowls of conical form are the commonest survival, and many are decorated with incised floral and foliate motifs. Lightly molded decoration occurs, as well as "combing" of the clay. The *mei p'ing* vase is found with this glaze; it has a tall, rather straight body with a short narrow neck and was intended to hold a single spray of prunus blossom. Stem cups, deep bowls, and ewers have also been noted, though some of the ewers which have appeared in Europe latterly are forgeries. Bowls sometimes have the rim bound with copper.

Identification of Sung Ware.—Because of the many later copies of Sung wares, and in particular those of the Yung Cheng period, it will be profitable at this point to mention the work of Robert T. Paine Jr. and W. J. Young of the Boston Museum of Fine Arts on the "bubble" structure of some of these glazes (Boston Museum of Fine Arts, *Far Eastern Ceramic Bulletin*, vol. v, no. 3 [1953]). From the Sung period the majority, of which *Kuan* is a typical example, contain a large number of bubbles which can be seen under a good magnifying glass. These, together with crystals which form on cooling, made the glaze appear dense, and, in extreme cases, almost opaque. By means of photomicrography Paine and Young have shown that various glazes exhibit a characteristic pat-

tern which, in conjunction with other indications, can be used to determine the date of manufacture with a reasonable degree of accuracy. The bubble structure of northern celadons, for instance, is distinctly different from that of Yüeh ware, and both are distinguishable from Lung Ch'üan glazes. Whatever the surface resemblances between the Sung *Kuan* glaze and that of the 18th-century copy, magnification shows an unmistakable difference.

6. Yüan Dynasty (1280-1368).—The Yüan, or Mongol, dynasty is often regarded as being no more than transitional between the Sung and Ming dynasties. This is not entirely true. Undoubtedly many Sung types were continued, just as T'ang types were continued at the beginning of the Sung dynasty, but there are other wares which are a new departure. The manufacturing centre of Kingtechen increased in importance and first manufactured the white translucent porcelain which was to have a revolutionary effect on Chinese wares. The use of painted decoration, begun during the Sung period at Tz'u Chou, also became much more widespread, and the two techniques were combined in a manner which later affected the course of porcelain manufacture throughout the world.

The *Ko-ku-yao-lan* of 1387 refers to *shu fu* ware, a type of white porcelain which sometimes bears the characters representing *shu fu* ("central palace"), probably because of its imperial associations. This has been identified with existing specimens of white porcelain covered with a fairly dense bluish glaze. It appears to be related to the earlier *ying ch'ing* ware and probably developed from it. The base is unglazed. Decoration in relief, painted in slip or engraved, is to be seen on most surviving examples. Much more unusual is the appearance of a few specimens, almost certainly of Yüan date, which are painted with reduced copper red under the glaze. This technique was certainly not derived from the Middle East, but it is possible that it came originally from Korea. As mentioned above, the potters of Chün Chou had achieved this colour but only in the glaze.

The use of underglaze blue was definitely introduced from the Middle East where it was used at least as early as the 9th century, specimens thus decorated having been recovered at Samarra. The best-known example of Yüan porcelain decorated in this manner, which is usually referred to as blue and white, is a pair of vases in the Percival David collection in London. They bear a date equivalent to 1351. The accomplished handling of the decorative motif implies an advanced technique rather than a recent introduction, and suggestions that blue painting of this kind may have been done during the latter part of the Sung dynasty are therefore easier to accept than formerly. A pair of vases in the collection of Mrs. Alfred Clark have been dated to this earlier period.

As mentioned above the wares of Tz'u Chou are notoriously difficult to date accurately, but many of the brown-glazed wares with carved decoration belong to the Yüan, rather than to the Sung, period. Some of the painted wares, too, have certainly been awarded too early a date. It is almost as difficult to differentiate between late Sung, Yüan, and early Ming celadons. The Mongol conquests led to an opening of trade with many parts of the world to the west of China, and goods of all kinds were freely exported. It must, therefore, be assumed that manufacture of the exportable kinds of pottery was on a much larger scale at this time, and more specimens are likely to have survived from this than from the Sung period. The makers of celadons—one of the principal export wares—were distinctly conservative. However, some variations in form during the Yüan dynasty are noticeable, and the peony scroll, carved or in applied relief, is a typical motif, also appearing on some early blue-and-white wares.

7. Ming Dynasty (1368-1644).—The Mongol emperor Shun Ti was defeated in a popular uprising, and the first Ming emperor, Hung Wu, succeeded him in 1368. When the country had recovered from these internecine struggles the ceramic art took a new lease of life, though under somewhat changed conditions. The Sung monochrome wares, the celadons, Chün wares, etc., went out of favour and the old factories sank into obscurity, while the fame and importance of the great porcelain town of Kingtechen, near the P'o-yang Lake in Kiangsi Province, overshadowed all the rest. The imperial factory there was rebuilt and reorgan-

ized to keep the court supplied with fine white porcelain; Chinese ceramic writers thenceforward speak of Kingtechen and little else.

The neighbourhood of Kingtechen had long been noted for its excellent ceramic wares. All that the industry required in the way of material was lavishly supplied by the neighbouring hills, kaolin (china clay) for the body of the porcelain, petuntse (china stone) to mix with it and to form the glaze, and wood ashes for fluxing purposes. The staple product of Kingtechen is the fine white porcelain which has made "china" a household word throughout the world; and as this ware lent itself peculiarly well to painted decoration, the vogue for painted porcelain rapidly replaced the old Sung taste for monochromes.

Some blue-and-white specimens exist with the four-character mark of Hung Wu, and although R. L. Hobson comments that they seem unduly advanced for the period, the present antedating of the use of underglaze blue makes them much more acceptable. The reign of Yung Lo (1402-24) is remarkable for some extremely thin-walled pieces, referred to as *t'o t'ai*, or "bodiless ware." Engraved examples are known, and the Chinese commentaries refer to specimens decorated in red, agreeing with the mid-20th century attribution of the use of underglaze copper red to the Yüan dynasty. Some white bowls of conical shape are also ascribed to this reign.

After this early period Ming wares, generally, are fairly easily recognizable. Porcelain replaced stoneware as the usual medium, and polychrome decoration became widely employed. The wares lack much of the precision of the porcelain made during the following Ch'ing period (1644-1912), when a kind of factory system grew up which divided the work into a large number of repetitive operations. Little trouble was taken to smooth over imperfections of manufacture and footings are often finished summarily. The glaze, too, frequently has minor defects, and articles such as vases are often slightly distorted and carelessly finished. The shape of many examples can fairly be described as "massive," in spite of the fact that most of them were made for export and the difficulties of transporting them must have been considerable. None of these factors ought to be regarded as evincing a lack of skill, especially as the potters were quite capable of technical virtuosity when they wished to display it—some of the most thinly potted of all Chinese porcelain belongs to this period. It seems that the Ming potters disdained the attitude of mind which treated blemishes as important, and occasional distortions were regarded as lending interest to an object. The Chinese did not carry this aesthetic creed to the same lengths as the Japanese, but the difference seems to be largely one of degree. Ming wares can fairly be described as masculine, in contrast to the more feminine qualities of the later Ch'ing wares.

The largest single group of Ming porcelain is that painted in blue underglaze, and much of the pigment used was imported from Middle Eastern sources. The Chinese sources of cobalt were adulterated with manganese, and the colour was defective. Persian cobalt, on the other hand, was inclined to run, and the best results were obtained from a mixture of the two. Supplies of this so-called "Mohammedan blue" (*hui hui ch'ing*), which came from the Kashan District of Persia, were not always obtainable and were interrupted on more than one occasion. The quality of the blue painted wares, however, remained to a great extent dependent on its use until the end of the 16th century when methods of refining native cobalt were devised.

Reign of Hsüan-te (1425-35).—In this reign the arts were particularly fostered and a high level of achievement attained. The blue painting was blackish in colour, with dark spots at intervals where thick blobs of pigment were deposited by the brush—the "heaped and piled" effect referred to by the 19th-century commentator, Lan Pu (see *Bibliography*). This style was deliberately copied in the 18th century, often with the appropriate reign mark, but its contrived nature is usually apparent. The motifs were floral and foliate, with the occasional use of fish and waterfowl. Sometimes vessels are bordered by a pattern of conventional rocks amid waves—the "Isles of Immortality"—usually referred to as the "Rock of Ages" pattern. This may have been first used during the 14th century, and it appears frequently throughout the Ming period and later. It can also be seen on Persian copies of Ming blue-and-white wares and, in a much debased form, on some pottery from Iznik (Anatolia) during the 16th and 17th centuries. The cobalt pigment said to have been exclusively used during this reign and the preceding reign of Yung Lo was neither from Middle Eastern nor native sources. It was referred to as *su-ni-po*, or *su-ma-ni*, and is discussed in the *Shih-wu Kan-chu* by Huang Yicheng, published in 1591. *Su-ni-po* has tentatively been translated to mean "Sumatra" as it appears that envoys from that country brought tributes of cobalt blue to China from 1426 to 1448. Supplies of cobalt also reached China from East Africa, probably from Zanzibar, and it may well be that "Zanzibar" would be a better reading.

References to underglaze copper red become much more definite in contemporary commentaries. It is often called "sacrificial red" for some reason which cannot be determined. To a great extent sacrificial red was abandoned later in the dynasty in favour of overglaze iron red, although it was used again during the reign of the Ch'ing emperors, K'ang-hsi (1661-1722) and Yung Cheng (1723-35), and appears in a rather primitive form from some provincial kilns. Most existing examples of Hsüan-te types such as the stem cups with three fish in silhouette are 18th-century copies. Both cobalt blue and copper red were used as monochromes, and occasionally together, but since these pigments required a slightly different firing temperature one or the other is usually deficient in quality.

The use of enamel colours was rare and the technique had by no means been fully mastered although some specimens decorated in primitive red, green, and yellow enamels had been made at Tai' Chou as early as the Sung period.

Ch'eng Hua (1464-87).—Records between the time of Hsüan-te and Ch'eng Hua are meagre, and specimens which can be attributed to it with any degree of accuracy are few. Most enameled decoration, however, can be attributed with a reasonable measure of certainty to the reign of Ch'eng Hua, the finest examples being, perhaps, the "chicken" cups, so called because they are decorated with chickens. Their decoration is outlined in underglaze blue and filled in with soft enamels called *tou ts'ai*, or "contrasted colours." These were much imitated later. Ku T'ai in the *Po wu yao lan*, a commentary published in 1627, refers to Ch'eng Hua enamels as being thin, subdued in colour, and pictorial in effect, which accords with the little now known about them. He also mentions that the *su-ni-po* blue was no longer available and that the blue and white was poorer in quality.

The practice of enameling directly on to unglazed porcelain (biscuit) instead of on to a glazed and fired body is sometimes thought to have begun in this reign, though that of Chia Ching (1521-66) is the more likely. Ming specimens are, in any case, extremely rare, and most belong to the reign of K'ang-hsi (1661-1722) in the Ch'ing dynasty. The enamel covers the whole of the biscuit surface, and the difference between the two techniques is marked. The style of decoration, too, is different, although this was sometimes imitated in overglaze enamels.

Like the mark of Hsüan-te, that of Ch'eng Hua has been much copied later, and true examples are exceedingly scarce.

Hung Chih and Cheng Te (1487-1521).—The first use of a coloured overglaze ground can be attributed to the reign of Hung Chih (1487-1505), when a yellow of variable shade first appears. The blue-and-white motifs of the reign of Cheng Te (1505-21)

show the influence of the Muslim palace eunuchs who supervised the imperial kilns. "Mohammedan blue" was again available, and arabesques and Arabic inscriptions appear on some examples of porcelain made at Kingtechen. The "Mohammedan scroll" is composed of somewhat formal flowers joined by S-shaped stems, with scroll-like leaves at intervals along them. The earliest versions of this theme, which seems originally to have come from a textile pattern, are the least stiffly drawn. The linear style of painting previously employed altered to one where outlines were filled in with flat ungraduated washes.

Chia Ch'ing (1521-66).—This reign is notable for a deterioration in the quality of the porcelain body, offset by the use of rich dark blue. The latter may have been due to fresh imports, or to the discovery of native deposits at Jui-chou (Kao-an) in Kiangsi Province. The technique of using this colour had obviously been mastered, because there is no sign of running. Enamelled wares, too, were executed in good colours, with well-marked outlines. A characteristic colour, the opaque tomato-coloured iron red (*fan hung*), was used as a monochrome with gilt traceries over it on bowls which sometimes had interior decoration in underglaze blue. Various wares have decoration in red and green, a scheme which became more familiar later. A yellow glaze is found in conjunction with incised decoration (usually a dragon) in green. Very rarely was a green or blue monochrome used.

Lung Ch'ing and Wan Li (1566-1620).—The styles of Chia Ch'ing were, to some extent, continued in the following reigns of Lung Ch'ing (1566-72) and Wan Li (1572-1620). A palette which contained underglaze blue in conjunction with green, yellow, aubergine purple, and iron red (the precursor of the later Ch'ing *famille verte* palette), was known as *wan li wu ts'ai* or "Wan Li five-colour ware." Continuation of the red and green decoration is also to be seen, and vast quantities of blue-and-white porcelain were produced for export. The body is quite unlike that used earlier in the dynasty, being thin, hard, crisp, and resonant. It is the commonest of all Ming wares in the West.

During this reign much pierced work (*ling lung*) was done. It is sometimes called *kuei kung* ("devil's work") in allusion to the almost supernatural skill needed. Pierced objects range from small brush pots to vases covered with coloured glazes, and their artistic importance is usually in inverse ratio to the amount of time and manual dexterity lavished on them.

The Ming dynasty ended in 1644. The wares of the last three emperors, for the most part, had followed styles already established though perhaps an exception can be made for blue and white, which shows a number of new departures in both form and decoration. Many of the vases are without a footring and stand on a flat base. Forms based on European wares were obviously made for export. A few examples with cyclical dates (*i.e.*, inscriptions referring to one of the 60 year "cycles" rather than to the reign of an emperor) enable these wares to be dated accurately. These transitional wares are discussed in detail by Soame Jenyns in "The Wares of the Transitional Period Between the Ming and the Ch'ing, 1620-1683," *Chinese Art Society of America*, ix (1955).

Provincial and Export Wares.—The wares hitherto discussed were made, for the most part, in the Kingtechen area; it remains to consider the other wares of the period. The export of celadons went on, not only to the countries west of China but also to Japan where they were much esteemed. Vast collections of these and other Ming wares gathered together by the sultans of Turkey are still at Istanbul and have given particularly valuable assistance in dating. Most celadons attributable to the Ming period have incised under the glaze floral and foliate decoration of a kind which also appears on blue painted wares, and the drawing is distinctively Ming in style.

The Tz'u Chou kilns continued working, the traditional nature of their styles once again making it difficult to date wares accurately. The forms of the vessels are probably the safest guide. Many of the pillows (which are more comfortable than they appear) belong to the Yüan and Ming periods. Decoration which includes Taoist figures can probably be placed to the reign of Chia Ch'ing, when Taoism was in the ascendant. It is difficult to sepa-

rate Ting wares made after the Sung dynasty from some of those made earlier. A type known as Kiangnan Ting from Anhwei, which is creamy in colour and sometimes has a brown tinge in the glaze, was made during Ming times and continued into the Ch'ing period. Some of the Chün wares made during Ming times may be wrongfully attributed to Yüan or Sung, and the "soft Chün" types probably belong almost exclusively to the Ming period. *Temmoku* wares were undoubtedly continued.

The fine porcelain of Te-hua in Fukien Province was first made, perhaps, in the early part of the dynasty, although some authorities are inclined to regard it as later. Most of this porcelain was left undecorated, and received the name in Europe of *blanc de chine*. The glaze is exceptionally thick and lustrous, and early examples are often slightly ivory in tone, although this can by no means be relied upon to identify them. Enameling is infrequent; and virtually all enameled specimens, figures or vessels, have been decorated in Europe, usually in the Netherlands. Figures especially were made here, the Buddhist goddess Kuanyin being a favourite subject. Most examples belong to the 17th and 18th centuries, and even later. Detachable hands and heads probably indicate an early date.

The stoneware of I-hsing in Kiangsu Province is extremely important and its teapots were much valued in 17th-century Europe where tea was newly introduced. It was known in the West as

boccario ware and was copied and imitated at Meissen, Ger., in Staffordshire, Eng., and in the Netherlands by Arij de Milde and others. The wares of I-hsing are unglazed, the body varying from red to dark brown. The molding is extremely precise and was often sharpened by grinding on a lapidary's wheel. The body was sometimes polished in the same way. Copies of Chün, Ko, and Kuan glazes were made at the same kilns.

The kilns of Kwangtung also copied some of the Sung glazes, the most notable being the Chün types of which "Fatshan" Chün has already been mentioned (see *Sung*, above). Some celadons

are also reputed to come from this district.

Most of the Ming stoneware ridge tiles and roof finials were made at kilns near Peking. Many of them are decorated in green, yellow, turquoise, and aubergine purple glazes, recalling the wares of the T'ang dynasty. A Ming date is exceedingly optimistic for most of them. To this group belong, perhaps, a few large figures which have sometimes been doubtfully awarded a T'ang date.

The provincial tile kilns also manufactured the so-called *san ts'ai*, or "three-colour wares," perhaps originally a product of the Tz'u Chou kilns. These were decorated with coloured glazes which were often kept from intermingling by threads of clay (the so-called *cloisonné* technique), or were used in conjunction with the *ling lung* technique. Others have engraved designs under the glazes. Most existing specimens are large vases, barrel-shaped garden seats, and the like. The best are extremely handsome and imposing, turquoise and dark-blue glazes being particularly effective. Copies have been made in Japan in modern times.

"Swatow" plates are a provincial type, perhaps made in Fukien for export. They are notable for a poor finish, often with a sandy base, and are decorated with sketchy but vigorous painted designs in underglaze blue, or, less often, in a limited range of enamel colours—usually red and green.

8. Ch'ing Dynasty (1644-1912).—The Ch'ing dynasty marks the beginning of the immense vogue for porcelain in Europe which was to reach its height during the first half of the 18th century. Its wares differ, for the most part, from those of the Ming period in a fairly distinctive manner. Potters now had their medium under almost complete control and their products are much more

precisely finished. Their finesse contrasts sharply with the struggles of potters in Europe where porcelain manufacture did not emerge from the purely empirical stage until the 19th century. Ch'ing wares are treated at somewhat greater length than those of the preceding periods, partly because of their greater diversity, but also because many varieties are fairly common in the West.

Dating is assisted by literary sources such as two letters of 1712 and 1722 written by Père d'Entrecolles, a Jesuit missionary who spent some years at Kingtechen. He not only described the various processes of manufacture in some detail but added many comments of considerable use and interest to the ceramic historian and collector. He records that some pieces were handled by as many as 70 men, each contributing a small part to the total effect, and this must surely be one of the reasons why many Ch'ing wares lack the freshness and spontaneity of Ming decoration. An important early collection was made by Augustus the Strong, elector of Saxony and king of Poland, who patronized the Meissen factory. The collection, much of which was acquired between 1694 and 1705, was at first housed in the specially acquired Japanische Palais, but was later transferred to the Johanneum, both in Dresden. Much of it was returned to Dresden by the government of the U.S.S.R. in 1959, but some had been destroyed by bombardment during World War II.

The most famous contemporary Chinese commentaries are the *T'ao Shuo* ("A Description of Pottery") by Chu Yen, published in 1774, and the *Ching-tê Chên T'ao-Lu* ("The Potteries of Ching-tê Chên") by Lan Pu published in 1815. However, even the best translations (see *Bibliography*) are not easy to read without a considerable fund of practical knowledge, and even this is not sufficient to penetrate the obscurity of some passages.

The 18th Century: Kingtechen.—The imperial kilns of Kingtechen were fortunate in their directors during the reigns of K'ang-hsi (1661–1722), Yung Cheng (1723–35), and Ch'ien-lung (1736–96), and these directors were still more fortunate in the support they received from the palace. K'ang-hsi, in particular, was a patron of the arts on a considerable scale.

Underglaze Blue and Red.—The blue painted porcelain of the Ch'ing dynasty has been somewhat neglected in the 20th century. This is probably due to the ridiculously high value placed on it during the latter years of the 19th century, when it was usually called "Nanking" ware. Even the best, which belongs to the reign of K'ang-hsi, hardly bears comparison with the finer Ming wares though its influence on European porcelain was far-reaching. Blue-and-white porcelain was exported to Europe in vast quantities, and much has survived. Many of the forms were especially made for export; the condiment ledge on plates and dishes, for instance, which had first appeared in the reign of Wan Li had been added for Western customers: the Chinese use the saucer-dish. The blue and white of the K'ang-hsi period has an extremely white body and the blue is exceptionally clear and pure. It is variable in shade and the design is executed in graduated washes within lightly drawn outlines, a point of difference from Ming wares. Many of the designs of the Ming period were still in use and, of the later patterns, those illustrating literary and historical themes, sometimes with an inscription and a cyclical date added, are probably the best.

Ginger jars decorated with prunus blossom reserved in white on an irregular blue ground, intended to represent the cracked ice of spring and sometimes described as "pulsating," were once valued exceptionally highly, although in the mid-20th century a more realistic attitude was taken toward them. During the 18th century, copies were made of the blue-and-white wares of Hsüan-te and Chia Ch'ing (1796–1820); pains were taken to make them as accurate as possible, even to an imitation of the "heaped and piled" effect, and many were marked falsely.

Underglaze copper red was also used during the period under review. Despite statements to the contrary, it is becoming apparent that this pigment was never entirely abandoned, but merely became unpopular. The stem cups of the Yung Cheng period with three fruit or three fish in silhouette, which imitate those of Hsüan-te, are much better known than the wares they copied. Copper red also appears in conjunction with underglaze blue, and a green-

ish-toned glaze is common with pieces thus decorated. The designs are those of the period.

Underglaze blue was sometimes used as a monochrome ground colour. It was blown on to the surface in powder form before glazing, a bamboo tube, closed with gauze at one end, being employed for the purpose. For obvious reasons, it is called powder blue, or, in Chinese, *ch'ui ch'ing* ("blown blue"), and is distinct from the sponged blue grounds of the Ming dynasty. It was later used at several of the porcelain factories in Europe. *Clair de lune* (*yüeh pai*, or "moon white") is a cobalt glaze of the palest blue.

Coloured Glazes.—Copper red appears in monochrome form as

lang yao (the *sang-de-boeuf*, or "oxblood," of the French). *Lang* was probably the name of a potter; *yao*, of course, means ware. This glaze was also known to the Chinese as *ch'ui hung* ("blown red"). It was certainly used as a monochrome in early Ming times and possibly even earlier. It was the direct ancestor of the showy *flambé*, or transmutation, glazes of the Ch'ien-lung period which are referred to as *yao pien* and which are often vividly streaked with unreduced copper blue. These glazes are, of course,

also related technically to the purple-splashed Chün wares of the Sung dynasty, and to some of the glazes used on Kwangtung stoneware.

Another variation, no doubt at first accidental, is the glaze known in the West as "peach bloom," a pinkish red mottled with russet spots and tinged with green. The Chinese have various names for it, of which, perhaps, the commonest is *p'in kuo hung*, or "apple red." It is used on a pure white body. Most objects glazed in this way are small items for the writer's table.

Monochromes of all kinds are a distinct and important section of Ch'ing wares, and many reproductions of Sung monochromes were made. The use of iron as a pigment can be seen in a revival of the celadon glaze. The Kingtechen celadons have, generally, a pale green glaze over white porcelain, the white footring being given a wash of brown to simulate the old ware. Meanwhile, celadons of the Lung Ch'üan type were still being made and Père d'Entrecolles describes their manufacture. It is probable, therefore, that the kilns of Ch'ü Chou were still working in the old tradition. As well as the celadon glaze, iron was used to produce colours varying between café au lait and pale yellow, and also "dead leaf" brown. Sometimes panels were reserved in white and painted in enamel colours. Specimens thus glazed appear in the old Dutch catalogues as "Batavian" ware, because the wares were imported via the Dutch entrepôt at Batavia (modern Jakarta or Djakarta) in Java. They are also related to "mirror black" (*wu chin*), a lustrous colour obtained by the addition of manganese, and sometimes further decorated with gilding or even, as in at least one extant specimen, with both gilding and silvering. "Imperial" yellow, a lead glaze often used over engraved dragons and similar designs, was revived during the 19th century.

Brilliant turquoise glazes derived from copper have been produced up to the mid-20th century although later examples seldom have the quality of the earlier ones. The glaze is usually covered with a network of fine crackle and some examples have engraved decoration under it. Related glazes are the copper greens, for example leaf green and cucumber green, the latter being speckled with a darker colour. Apple green is an enamel colour used as a ground and applied over a cracked gray glaze. Most greens are relatively late.

Purple, or aubergine, glazes derived from manganese are seen occasionally. *Brinjal* bowls, decorated with engraved flowers, have an aubergine ground in conjunction with dappled green and yellow glazes. "Brinjal," in fact, means aubergine (eggplant) which is a favourite food in parts of the East. Bowls with engraved dragons and a combination of only two of these colours are somewhat better in quality.

Enamels.—These were sometimes used as monochromes. The use of iron red (*fan hung*) is an excellent example of the technique. It is sometimes called coral red, and it varies a little in shade. The surface is usually glossy but occasionally matt. The rose colour, discussed below, was certainly used in this way, and as a ground colour.

The wares enameled on biscuit are a much sought-after group. They are a development of the Ming *san ts'ai* wares, which were still being made during the Ch'ing period. The effect of painting directly on to biscuit was to produce a soft and distinctive colouring, which is extremely attractive. The outlines were first painted directly on to the unglazed surface in brownish black; some of the colours were then painted within these outlines and others were washed over them. Red or blue enamels, when they appear, are usually provided with a patch of glaze underneath them. The practice seems hardly to have survived the K'ang-hsi period, except for deliberately made later copies.

During the reign of K'ang-hsi the enameled wares were painted in the *famille verte* palette, usually over a white glaze. The name *famille verte* ("green family") is derived from the dominant distinctive green, but the wares are in fact a development of the Wan Li five-colour ware, the most important difference being the replacement of the earlier underglaze blue by an enamel blue. On most genuine examples it is possible to see a distinct "halo" round the enamel blue, but its absence does not necessarily condemn it as not genuine. The *famille noire* has the *verte* palette in conjunc-

tion with a black ground; the *famille jaune* uses the same colours, but with a yellow ground. In each case the white porcelain disappears under the enameling, and modern taste is inclined to award them a far lower aesthetic position than was once the case.

Toward the close of the reign of K'ang-hsi an opaque *rose* enamel appears. This and its related colours were called *yang ts'ai* or "foreign colours." It was discovered by Andreas Cassius of Leiden, Neth., and introduced about 1685. It is sometimes referred to as the "purple of Cassius," particularly in older works. It soon formed the characteristic colour of a group of wares, referred to as the *famille rose*, which was particularly developed

during the reign of Yung Cheng. It more or less replaced the *verte* palette although combinations of the *verte* and *rose* palettes can sometimes be found. The translucent enamels of the earlier period tend to become opaque, and painting is more feminine in style.

White Wares.—During the 18th century the white wares of Kingtechen were made mostly for the home market although a few were exported. They include examples of the *ts'o ts'ai*, or "bodiless ware," and the *an hua* (literally "secret language"). The latter has designs lightly incised or painted with white slip. The body is white, and the whole is

covered with clear glaze. The decoration can only be seen plainly if light be allowed to shine through it. This style is copied from a traditional Yung Lo (1402-24) type. *Ling lung* (pierced work) was revived in certain rare pieces inspired by jade; the use of piercing filled with glaze is derived from Persian Gombroon ware.

European Influence and the Export Trade.—Before mid-18th century some European wares had found their way to China, as witness certain copies of early Meissen porcelain. The taste of the European trader, though hardly representative of the more cultured section of Western civilization, also began to have considerable influence. Much decoration was done in studios in and around the port of Canton, white porcelain being sent from Kingtechen for the purpose. Enormous quantities of *famille rose* porcelain were painted there, including most of the so-called ruby-backed dishes which are completely covered on the reverse, except for the interior of the footring, with a ground of opaque *rose* enamel. These often have an elaborate arrangement of minutely delineated border patterns round the central subject (usually pretty women) demonstrating the new, and later widespread, idea that the beauty of an object is directly proportional to the amount of decoration on it. This theory was to be one of the causes of the degeneration of later Chinese and Japanese wares; it was, however, by no means confined to the Orient and can be seen in most 19th-century European porcelain. Its probable cause is discussed in the section *19th and 20th Centuries*, below.

The Yung Cheng painters were the first to carry foliate decoration over on to the back of the dish, usually as a prolongation of the stem. This was repeated later during the reign of Tao Kuang (1821-51). The European tendency to draw flowers in a naturalistic manner also appears in China from the Yung Cheng period onward, although it was not carried to the same lengths.

An attempt to imitate the European method of enameling, in which enamels were applied in flat washes which partly sank into soft porcelain glazes, can be seen in the so-called Ku Yüeh Hsüan ("Ancient Moon Pavilion") wares. These sometimes have a European subject, such as a Watteau shepherdess, but Chinese subjects were also used.

Of the wares more directly due to European intervention perhaps the best known is "Oriental Lowestoft," more correctly known as Chinese export porcelain. The first name is due to an

error on the part of William Chaffers, who persisted in attributing these wares to the small English factory at Lowestoft. If this porcelain is important at all, it is as a curiosity; the artistic value is nearly always negligible. The styles are usually based on those of European ceramics or metalwork, or on a combination of Western and Oriental motifs in an unpleasing *mélange confus*. The designs were provided by Western traders and coats of arms are comparatively common. The importance of this kind of decoration is that it enables a piece to be dated and traced to its origin with a measure of certainty. Another variety, known as "Jesuit" porcelain, was painted with crucifixions, nativities, and the like in sepia with a little gilding. Much rarer are specimens painted with secular subjects, which can usually be traced to a contemporary engraving. They are executed in a careful linear style which makes their origin obvious. Such wares are, however, a peculiarly unprofitable bypath in any study of Chinese ceramics.

Other wares connected with the export trade are those decorated with the so-called Mandarin patterns, which came from the Cantonese studios and were introduced toward the end of the 18th century. These have figure subjects in panels, which are surrounded with coloured grounds and an excess of floral and other ornament in unprepossessing combinations of colours.

Some specimens of *ling hung* imitate European pierced work, which was, in turn, copied from contemporary silver. Much white porcelain was sent to Canton to be decorated, but much, too, was shipped to Europe for the same purpose. Many examples were painted by German *Hausmaler* ("home painters") such as Preussler, by Dutch enamelers, and by English "outside decorators" such as James Giles. Decorated wares, usually those sparsely painted in underglaze blue, sometimes have added enamel decoration. Most of these were done by Dutch enamelers, and are usually termed "clobbered"—a word perhaps of Dutch origin. Dutch glass engravers also cut designs into some brown-glazed examples, a technique known as *Schnittdekor*.

Europe, of course, was not the only export market open to the Chinese. Much blue and white was exported to the traditional markets in Persia and the Near East, and Arabic inscriptions can be seen on some specimens. Of the other markets, India, Thailand, Burma, and Tibet deserve mention.

Other Kilns.—The wares discussed so far have been principally those of Kingtechen. Those of Te-hua in Fukien Province, however, are also important. Figures of Kuanyin in particular were exported in enormous quantities, and the *an hua* and pierced decorations often came from here. Vessels such as libation cups with applied prunus sprigs were copied by European factories in the 18th century, notably by those at Meissen (Ger.), Chelsea and Bow (London), and Saint-Cloud (France). The body is usually white, sometimes with an ivory tone, and the glaze is thick, rich, and lustrous. European forms are to be seen occasionally, and most coloured examples have been decorated in the West. The kilns of I-hsing also continued making the traditional wares.

19th and 20th Centuries.—The 19th century has little to offer which is new, or of good quality. Snuff bottles painted with miniature designs were first made toward the end of the 18th century, but most belong to the reign of Chia Ch'ing (1796–1820) and Tao Kuang (1821–51). The former reign can be regarded as an extension of the Ch'ien-lung period, although an increasing degeneration is obvious. Bowls with circular medallions painted in enamel colours with yellow or *rose* grounds are, perhaps, among the finer wares. Also of good quality are bowls covered with an opaque ground, *rose* or yellow, with designs engraved into it. These were first made in the 18th century and extend to the reign of Tao Kuang. The technique is referred to as *graviata*.

Most of the wares of Tao Kuang are poor in quality, although some examples in the style of Yung Cheng are a little better. The glaze has a "musliny" texture similar to that seen on some early Ming wares, and on Japanese porcelain from Arita. Translucent enamels over underglaze blue are a Yung Cheng type revived at this time. The *rose-verte* palette was commonly used.

In 1853 the T'ai P'ing Rebellion led to the destruction of the kilns at Kingtechen, and these were not rebuilt until 1864. The reign of T'ung Chih (1862–75) is principally notable for poor

copies of some of the earlier monochromes, including the "peach bloom" glaze. Nearly all wares from this time onward are slick copies of older work. Criticism is chiefly directed against them on the ground that they are sometimes passed off as genuine, but as decoration they are often much more pleasing than many 20th-century European wares.

9. Marks.—It is difficult to give much practical assistance on the question of Chinese marks. Most of them give the name of the dynasty and that of the emperor, and reference to any of the standard books on the subject will enable the reader to ascertain the meaning. However, many of them have been used so inconsequentially that unless the period can also be assigned with reasonable certainty by other means, it is better to disregard them. The most abused are those of Hsüan-te and Chia Ching. Hardly less abused in the 19th century is the mark of Yung Cheng. Although not unknown, the genuine mark of K'ang-hsi is comparatively rare since it was thought that to put the name of the emperor on something like porcelain, which might be broken, was sacrilege. Reign marks do not often appear before the Ming dynasty, although there are a few earlier examples. Studio marks and devices are seen occasionally, and most of them are given in the better books of marks (see *Bibliography*). Inscriptions were often used as decoration, and sometimes include cyclical dates, which are to be found in some books of marks. There is a distinct difference between Ming and Ch'ing calligraphy which will be apparent to anyone familiar with Chinese ideograms.

10. Symbolism.—Chinese decoration is usually symbolic and often exploits the double meaning of certain words: for instance, the Chinese word for bat, *fu*, also means "happiness." Five bats represent the Five Blessings—longevity, wealth, serenity, virtue, and an easy death. Longevity is symbolized by such things as the stork, the pine, and the tortoise, the *ling chih* fungus, and the bamboo, all reputed to enjoy long life. The character *Shou*, which also denotes longevity, is used in a variety of ornamental

forms. Together the peach and the bat represent *fu shou*, long life and happiness. The "Buddha's hand" citron, a fruit with fingerlike appendages, is a symbol of wealth, and each month and season is represented by a flower or plant. The *Pa Kwo*, consisting of eight sets of three lines, broken and unbroken in different combinations, represents natural forces. They are often seen in conjunction with the *yang-yin* symbol which represents the male-female principle and which has been well described by R. L. Hobson as resembling "two tadpoles interlocked." The dragon is too well known to need description, but generally it is a mild and beneficent creature. It is a symbol of the emperor, just as the *feng-huang* (a phoenix-

like creature) symbolizes the empress.

There are three principal religious systems in China: Confucianism, Taoism, and Buddhism. The Taoist gods, in particular, appear frequently on porcelain as decoration. The most important, Lao Tzu, has a large and protuberant forehead. He is usually accompanied by the Eight Immortals (Hsien) and these are sometimes modeled as sets of figures. The eight horses of the emperor Mu Wang (Chou dynasty) are also frequently represented. The Buddhist goddess, Kuanyin, and the Eighteen Lohan, disciples of Buddha, were also modeled. The Eight Buddhist Emblems appear fairly frequently, as well as the Eight Precious Things, and a collection of instruments and implements used in the arts known as the Hundred Antiques. The Lions of Buddha (often miscalled dogs) are frequently represented, as well as the kyllin (properly the *chi-lin*) which is a composite animal, not unlike a unicorn.

which has a fierce appearance but gentle disposition.

Most of these symbols were not used in ceramic decoration before the Ming dynasty, although both the dragon and the *fêng-huang*, as well as some floral motifs, are earlier. The *lei-wên*, however, which resembles the Greek key fret and is sometimes used on the later ceramic wares, appears on bronzes as early as the Shang and Chou dynasties, where it is called the "cloud and thunder" fret. The *t'ao t'ieh*, a grotesque mask of uncertain origin, also appears on early bronzes, and on later pottery and porcelain. Decorations based on Chinese literary sources are usually extremely difficult to trace to their origin.

G. KOREA

The chronology used in discussing Korean wares is comparatively simple. The early period, the Silla dynasty (57 B.C.-A.D. 935), is roughly contemporary with that period in Chinese history which runs from the Han to the T'ang dynasty. The Koryo dynasty (918-1392) covers approximately the same period of time as the Sung and Yüan dynasties, and the Yi dynasty (1392-1910) almost exactly parallels that of the Ming and Ch'ing. Precise dating of almost all existing specimens, however, is virtually impossible.

Korea lies to the north of China and close to the islands of Japan. It has, therefore, usually formed a cultural link between the two countries. For instance, during the Japanese invasion of 1592 many Korean potters were taken to Japan, where they were set to work making Tea Ceremony wares which had hitherto been imported, and they later helped to found the porcelain industry.

1. Silla Dynasty (57 B.C.-A.D. 935).—It is difficult to distinguish some Korean wares from those made in the northern provinces of China. The wares of the Silla period include some which are reminiscent of those of the Chou dynasty. Specimens of stoneware, obviously based on metalwork, are distantly related to some of the Han bronzes. Patterns on these wares are geometric, and incised into the clay before firing. An olive-green glaze was introduced later in the Silla dynasty, probably about the 9th century, while some unglazed gray vessels with incised or impressed decoration are sometimes said to recall T'ang wares, but the resemblance is extremely slight. Roof tiles and finials have a brown or a green glaze, and may be contemporary with the Han dynasty.

BY COURTESY OF MUSEUM OF FINE ARTS, BOSTON. HOYT COLLECTION

2. Koryo Dynasty (918-1392).—The wares of the Koryo dynasty exhibit a much greater diversity, and fall into rather more clearly defined groups. The attribution of certain black-glazed *temmoku* types is controversial, but it seems that at least some were made in Korea. Many celadons, too, have typical Korean lobed forms, based on the melon or the gourd. These are also to be seen in porcelain, much of which has a bluish-white glaze. Some lobed boxes, usually circular, are decorated with impressed designs and are probably always Korean.

One of the difficulties in the study of Korean pottery is that practically everything has been recovered from tombs; few actual kiln sites have been discovered. Nevertheless, one such excavation at Yuch'on-ri has disclosed sherds of both the celadon glaze and of white porcelain from which it seems evident that white porcelain resembling both the *ying ch'ing* and Ting types was made (see *China: Sung Dynasty*, above). The earliest vessels were probably fairly close copies of Chinese styles, and the distinctive Korean style of many examples followed rather later. A crazing of the glaze and a certain amount of flaking are characteristic. A mere handful of specimens, some fragmentary, of inlaid white porcelain

have survived. They are best represented by a vase in the Prince Yi Museum in Seoul, which has panels of black-and-white inlay beneath a celadon glaze. Decoration on much Korean porcelain of the period is either incised (foliage being a frequent motif), combed, or molded in shallow relief.

Korean celadons are mentioned in Chinese writings of the 12th and 14th centuries. They have a stoneware body covered with a glaze which varies from bluish green to a putty colour, and some are obviously analogous to the celadons of Yüeh-chou discussed in the section *China: Han Dynasty*. Characteristic of Korean pots are the "stilt" or "spur" marks to be seen on the otherwise glazed base; these are the points on which it rested in the kiln. Many of the forms are lobed. Perhaps the most important divergence from the usual Chinese celadon is the presence of inlaid decoration beneath the glaze of many specimens, later examples of which are often referred to as *mishima*. (*Mishima* is a Japanese term, sometimes said to have been borrowed from a Japanese town of the same name whose almanacs bore characters similar to the design on the pots; another, and more likely, explanation is that *Mishima*, or *mitsu-shima*, which means three islands, was a harbour on the sea route between Korea and Japan.) The designs were first incised into the clay, and the incisions were then filled with black-and-white clay in the form of slip. This technique seems to date from the 13th century, and was probably derived originally from attempts to paint in white slip under a celadon glaze; one or two rare examples of Chinese celadons from Lung Ch'üan thus decorated have survived. The inlaid patterns are diverse but most of the subjects are floral; birds are to be seen occasionally. Isolated flowers with symmetrically radiating petals are also found, principally on boxes.

3. Yi Dynasty (1392-1910).—While most Korean wares of this period are distinctly rougher than those of China, the decoration is often magnificent in quality. Most can be clearly distinguished from Chinese wares by their forms, which show distinct differences in almost every case. Lobed forms suggested by the melon are very characteristic, and the pear-shaped bottle differs in its proportions from that of the Chinese. The large rugged jars with high shoulders are not so precisely potted as similar jars from China, often showing a marked degree of asymmetry. "Twisted rope" handles are also peculiar to Korea. Many of the ewers in particular are obvious adaptations from metalwork.

Painting in brownish black beneath a celadon glaze, which had begun in the Koryo dynasty and has an obvious relationship to some of the work or Tz'u Chou, continued in the Yi dynasty. Inlaid decoration was also executed during the early part of this period, the pattern often being engraved by stamps rather than incised freehand. *Sgraffito* decoration, in which patterns were incised through a grayish-white slip, is also seen occasionally.

Some excellent painted designs in an underglaze blue of variable colour, but usually distinctly grayish in tone, were executed on a rough porcelain body which is almost stoneware. They are particularly notable for great economy of brushwork and superb drawing. Their affinities are much more with Japanese pottery than with contemporary Chinese wares. A typical Japanese technique, *hakeme* (from *hake*, "brush"), or brushed slip, is used in conjunction with painted decoration in the early part of the dynasty, but later it is used alone. Korean influence on Japanese pottery was probably at its strongest during the ascendancy of the Japanese warrior Toyotomi Hideyoshi (1536-98) who invaded Korea. Although it is difficult to date Yi wares pre-

cisely, it is unlikely that much important work was done in Korea itself after this invasion.

H. JAPAN

Japanese ceramics have not received such close attention in the West as those of China, and interest has been chiefly centred on its porcelain.

Since Japan is a well-wooded country, wood has always been used for domestic utensils of all kinds, either in a natural state or covered with the sap of the *Rhus vernicifera* tree in the form of lacquer. Until recent times, therefore, pottery and porcelain were not employed extensively for general domestic use, but were reserved for such special purposes as the Tea Ceremony (see below). In pottery the Japanese especially admire accidental effects which resemble natural forms. Objects which appear misshapen and glazes which exhibit what would normally be regarded as serious imperfections in China or the West are admired by the Japanese connoisseur. The Western student has to learn and adopt new criteria of judgment which are, nevertheless, equally valid. The Japanese potter liked his work to reveal the impress of the hand which had made it. Marks such as the ridges left by the fingers in a newly-thrown vessel were frequently accentuated instead of being obliterated, and marks made by tools were often left untouched. Hand modeling was practised long after the wheel was known, and asymmetries and irregularities of form were purposely sought. Similar accidental effects were encouraged in glazing; coloured glazes were allowed to run in streaks and were irregularly applied. They were often thick, with many bubbles, and with a semifluid or treacly appearance. Crackled glazes and those deeply fissured (the latter being termed "dragon skin" or "lizard skin") were deliberately induced. Painted decoration, frequently blue, brown, or iron red, is often summary, and almost calligraphic in its simplicity. The aim was to give an overall effect which resembled natural objects, such as stones, in being totally uncontrived.

From the 15th century onward the art of the potter was also affected by the elaborate Tea Ceremony (*q.v.*). In fact this ceremony (the *cha-no-yu*) assumed such importance that a brief description is necessary. In its original form it was probably introduced from China by Zen priests, but at the court of the Shōgun Yoshimasa (1435–90) in Kyōto it developed into a fixed ceremonial pattern. It is held in a small room or pavilion, usually with a carefully laid out garden surrounding it. When the guests are summoned they enter a sparsely furnished room through a very low doorway. In a recess called the *tokonoma*, a picture mounted on brocade or silk is hung, and the guests bow to this in appreciation. The Tea Master puts a little powdered tea in a bowl and pours on it hot water which has been heated over a charcoal brazier. The tea is whipped to a froth with a bamboo whisk, and then passed from hand to hand. The various utensils (the tea-bowl, tea caddy, water container, boxes, plates, and iron tea kettle) have been carefully selected by the Tea Master and are often of great age. The tea drinking is followed by a discussion and appreciation of their qualities. The bowls are valued for their heat-retaining properties and the way in which they fit the hand as well as for their appearance. Sometimes a newly acquired work of art is produced by the host for the delectation of his guests. Possibly the ceremony was first exploited as a means of settling feudal disputes, and the fact that guests must crawl into the room is thought to have prevented them from concealing a sword under their robes. Since the Tea Masters were the aesthetic arbiters, their influence on Japanese ceramics was profound.

1. Early History.—The early history of Japan is considerably more obscure than that of China. The first Japanese pottery belongs to the Jōmon period (c. 2500–250 B.C.) and has a black body. Decoration is usually an impressed representation of coiled rope or matting, and *jōmon* actually means "coiled." At one time this pottery was thought to have been made by the Ainu people who migrated from Siberia and were the first inhabitants of Japan, but this is now doubtful. Jōmon-*shiki* ("pottery") is widely distributed throughout the islands but complete specimens are very rare. It was followed by Yayoi pottery, so called because the

first specimens were discovered in the Yayoi quarter of Tokyo in 1885. Specimens of this, too, have since been excavated throughout Japan. The body is somewhat finer in quality than Jōmon pottery and is usually red or gray. Decoration is simple, and forms sometimes show the influence of Korean pottery of the period. It ceased to be made about the 6th century A.D. Meanwhile, from about the 3rd to the 6th century A.D. large tombs were constructed in the form of oval or circular tumuli from whose bases have been recovered the so-called *haniwa* (*hani*, "clay"; *wa*, "circle") figures of warriors, women, horses, and so forth. These are hollow and are more primitive than analogous figures from China though they are vigorously modeled.

In the Asuka or Sueki period (A.D. 560–710) which followed wares are much more sophisticated. Unlike the preceding types, they were made with a wheel and firing took place in a rudimentary kiln at a much higher temperature than previously. Widespread manufacture persisted through the Nara period (710–784) and the early part of the following Heian, or Fujiwara, period (784–1185). Some examples have a smear glaze, no doubt at first caused accidentally by wood ashes coming into contact with the surface. Three colours of glaze—green, yellowish brown, and white—were used either alone or in combination and resemble those of T'ang china. Pottery of this kind has been found around Ōsaka and Kyōto. Examples can also be seen in the Shōsō-in, which is a windowless pavilion in the grounds of the Temple of the Great Buddha at Nara. This contains a large collection of various works of art given on the death of the emperor Shomu, in 756—possibly the earliest instance of an art collection being left to posterity and still surviving. The principal pottery productions of the period were vases, dishes, bowls, and bottles of various kinds. The influence of Korea and of T'ang china is noticeable, and many of the objects in the Shōsō-in come from China, and some from much farther west. Toward the end of the Heian period contacts with China were severed, and there was a corresponding decline in the art of pottery; even the traditional Sui-style ware disappeared.

2. Kamakura and Muromachi Periods (1186–1573).—A revival in the Kamakura period (1186–1335) followed the visit of the potter Kato Shirozaemon (Toshiro) to China in 1223, in company with a Zen monk named Doyen. Here Toshiro learned the secrets of pottery making, and he later established himself at Seto, in Owari (now Aichi Prefecture), which speedily became a large centre of manufacture. There were soon about 200 kilns in the vicinity making a variety of wares, some of which were glazed in black in imitation of the so-called *temmoku* wares of China. The early wares were mainly for ritual purposes, but by the beginning of the Muromachi, or Ashikaga, period (1335–1573) teabowls, plates, jars, and saucers of domestic utility were also being made. Wares of the Kamakura period are decorated with incised designs, or with impressed or applied ornament. The Muromachi wares are much plainer, due to the growing influence of the Tea Ceremony, especially the *Wabi* school of the cult which concentrated on rustic simplicity. The latter, too, have a feldspathic glaze which is more even in quality, the earlier glazes tending to run in rivulets. A transitional type has a soft yellowish glaze, and a dark brown glaze is sometimes called Seto *temmoku*.

A large number of kilns were in use, the more important being known as the "six pottery centres of ancient Japan." These were Seto; Tokoname (also in Aichi Prefecture) which may have exceeded Seto in the size of its production; at Bizen (Okayama Prefecture), which has produced an excellent unglazed stoneware from the Heian period to the mid-20th century; at Tamba (Kyōto Prefecture); at Shigaraki (Shiga Prefecture); and at Echizen (Fukui Prefecture). The wares of Seto, especially those made for Buddhist ceremonies, are regarded as the finest, and *seto-mono* is sometimes used as a generic term for pottery and porcelain.

3. Momoyama Period (1574–1603).—*Seto-Mino Wares.*—Production had been interrupted during the civil wars of the 15th and 16th centuries, and toward the end of the latter century the Seto kilns were removed for a time to the Gifu Prefecture. Mino Province where they received the protection of the daimyo of Toki. The Mino pottery was founded by Kato Yosabei Kage-

mitsu, and his sons started other potteries in the vicinity, notably that under the aegis of the Tea Master Furata Oribe Masashige. The later wares of these kilns are much less austere than those attributed to the Muromachi period since the cult of the Tea Ceremony, though now widespread, had lost something of its earlier simplicity. New kilns were also built and pottery, as well as retaining its importance in the Tea Ceremony, became much more widely used for ordinary purposes. The inspiration for most of its shapes and designs came from the Mino region. Characteristic Tea Ceremony wares of the early years of the 17th century are *Shino*, which has a thick, crackled glaze and is sometimes summarily painted in blue or brown; *ki-Seto*, or yellow Seto, whose crackled yellow glaze covers a stoneware body; and, at Narumi in the adjoining Owari region, a ware of the kind associated with Oribe (which had become a generic term for pottery influenced by the Tea Master of that name) which is glazed in white, straw colour, yellowish green, and pinkish red, with sometimes the addition of slight painting in brown. *Shino* traditionally takes its name from the Tea Master, Shino Ienobu, while *ki-Seto* is reputed to have been discovered by a descendant of Kato Shirozaemon.

Toward the end of the 16th century the Tea Ceremony was reformed by Sen-no-Rikyu (1520-91), the Tea Master to Toyotomi Hideyoshi (*q.v.*), who was principally responsible for the replacement of the hitherto much admired *temmoku* bowls from China by others influenced by unsophisticated Korean wares; his influence has persisted to the 20th century. In the 1590s Hideyoshi twice invaded Korea, and as a result of these wars many Korean potters were taken to Japan, where their influence was considerable.

Raku Ware.—A tilemaker named Ameiya, who is said to have been a Korean, introduced a new type of ware which was covered with a lead glaze and fired at a comparatively low temperature. His son Tanaka Chojirō and his family extended this technique to the Tea Ceremony bowl and their wares were brought to the notice of Hideyoshi about 1588, who awarded them a gold seal engraved with the word *raku* ("felicity"). These *raku* made in Kyōto by the Chojirō family are among the most famous of all Japanese wares. The shape of the vessels was extremely simple, a wide straight-sided bowl being set on a narrow base. At first the glaze was dark brown, but a light orange red was developed later, to be followed in the 17th century by a straw colour. Still later green and cream and other colours were introduced. Tea-bowls attributed to the first Chojirō are greatly valued in Japan, and numerous copies exist.

Karatsu Ware.—The kilns of Karatsu and district in the north of Hizen Province may have been established by Korean potters at this time since the influence of Korea is perceptible in some of them. The term Karatsu ware encompasses a great variety of shapes and styles: *muji-garatsu* ("undecorated"), *e-garatsu* ("painted"), *madara-garatsu* ("speckled"), *Chosen-garatsu* ("in the Korean style") which has a thick opaque glaze, and *Seto-garatsu* ("in the style of Seto") which has a white glaze. The earliest Karatsu ware belongs probably to the end of the 16th century, although it is sometimes awarded a still earlier date. Most surviving examples belong to the 17th century. The most valued pieces are those made for the Tea Ceremony.

4. Edo Period (1603-1867).—According to tradition the first Japanese porcelain was made at the beginning of the 16th century after Goradoyu-go Shonzui brought back the secret of its manufacture from Kingtechen. Another account claims that a Korean potter called Risampe, who was brought to Japan by Hideyoshi, discovered porcelain clay in the Izumi mountain, near Arita (Saga Prefecture); this version is feasible since no porcelain made before the end of the 16th century has been identified.

The first Arita manufacture was decorated in blue underglaze, and this is simple and excellent in quality. Specimens soon found their way to Europe in Dutch ships and the Dutch were awarded a trading monopoly in 1641. Some of these early Japanese wares are based on contemporary European metalwork and faience. They have, in the past, frequently been mistaken for Chinese export porcelain of the 17th century, and no doubt many such specimens are still misattributed.

The family of Sakaida is especially connected with the Arita kilns. The first recorded member, born about 1596, worked in underglaze blue until the family learned the secret of using enamel colours. According to tradition it was told to them by a Chinese met by chance in the port of Nagasaki. Sakaida Kakiemon I perfected this overglaze technique at Arita in the Kan'ei era (1624-43). It was continued by his family and, since many of them were also called Kakiemon, the style has become known by that name. The palette is easily recognized—iron red, bluish green, light blue, yellow, and sometimes a little gilding. Many examples have a chocolate-brown rim, and octagonal and square shapes are especially frequent. Themes of decoration are markedly asymmetrical, with much of the white porcelain surface left untouched. This technique and style spread rapidly to other provinces and is of considerable importance in any historical examination of the ceramic art. It is not always realized that its influence on European porcelain manufactured during the first half of the 18th century was at least as great as that of Chinese porcelain. Augustus the Strong of Saxony had a large collection and named the building he acquired to house it the Japanische Palais. The style was much copied at Chantilly, France, where the prince de Condé collected it, and at Chelsea in England. A later Kakiemon development in which *nishikide* ("brocade") patterns in compartments were used at the suggestion of Dutch traders is less pleasing.

These later coloured wares from Arita became known as "Imari," the port from which they were shipped. An interesting development is the practice of shipping white wares to Europe where they were decorated by Dutch and other European enameleurs.

Of considerable importance, but more rarely seen in Europe, was the porcelain called Kutani which was made from clay discovered at Kutanimura (Ishikawa Prefecture) by Gotō Saijirō. The kilns were founded about 1652 and operated for approximately 60 years, being reopened briefly in the 19th century. Old-, or *ko*-Kutani porcelain is greatly valued and can be placed among the finest of the Japanese wares. The body is heavy, approaching stoneware, and the designs were executed boldly and in rich colours. At Okochi, near Arita, a factory was founded about 1660 by the prince Nabeshima with the aid of Korean potters using Arita materials. This ware was rarely exported, and is purely native in style. The Mikawachi kilns under the protection of the princes of Hirado made porcelain principally for his use. The delicate very white body is usually decorated in miniature style with underglaze blue. Kyōto imitated Sung celadons and the Ming green and red wares. Seto made no porcelain until about 1807; the first production was decorated in underglaze blue and enamel decoration dates from about 1835. Outrageously large and hideously decorated vases were made here for export during the 19th century.

The manufacture of pottery was continued during the 17th and 18th centuries and much of it is notable for its decoration. Toward the end of the 17th century Ninsei (Nonomura Seisuke) began work at Kyōto and was responsible for much finely enameled decoration on a cream earthenware body covered with a finely crackled glaze. Also at Kyōto, the work of Kenzan, who used rich and subtly coloured slips often as a background for plant motives, and of the Dohachi family, famous for their enamels, are among the wares which are much sought in Japan, although it is extremely difficult to refer specimens to them with any certainty. Most signed examples can only be said to be in their style.

5. 19th and 20th Centuries.—Japanese productions during the 19th century, in common with those in most other parts of the world, greatly deteriorated in taste. A typical product of the period is the so-called "Satsuma" pottery, most of which was not made at Satsuma, but at Kyōto and was then sent to Tokyo to be decorated especially for export. The designs are overcrowded and debased, and its popularity undoubtedly retarded a true appreciation of work in the Japanese taste among Western students and collectors.

Like Western pottery and porcelain manufacture in the mid-20th century that of Japan is largely industrialized, most products being derivative and likely to appeal only to uninformed taste. However, the Japanese tradition of pottery making in small, and private kilns continues. Japanese potters have gone to England to work and a few Western artist-potters, notably Bernard Leach of St. Ives, Eng., have worked in Japan and have been influenced by Japanese traditions.

The Arita kilns began to revive the old styles after 1830 and modern versions of porcelain in the Kakiemon style have appeared in Europe. Recent work in the manner of Nabeshima—a porcelain always exceedingly rare in the West—has provided material for controversy among collectors. These are all of relatively high quality. A great deal of porcelain decorated in a debased Imari style was exported during the 19th century, but manufacture seems to have been discontinued.

At the former Russian port of Dalny, which is now Dairen in Manchoukuo, a Japanese pottery makes poor copies of Chinese celadons of the 12th century, and much better imitations of the early wares of Tz'u Chou, some of which are marked with an impressed stamp. Imitations of old Chinese porcelain are still coming from the Japanese islands, but the factories cannot be identified.

I. THAILAND AND ANNAM

Pottery was made in the old Siamese capitals of Sukhothai and Sawankhalok. It is also thought that potteries persisted at Ayutthaya until the 18th century. Little is known of the early history

of the region, and definite information on its pottery is almost nonexistent. Dating for the most part has been by analogy with related Chinese wares, which greatly influenced Siamese work. It cannot be doubted that Chinese potters migrated southward, taking their knowledge with them.

Kilns have been excavated on the site of old Sawankhalok, about 200 mi. N of Bangkok. The principal type of ware is a grayish-white stoneware covered with a translucent celadon glaze which is usually grayish green in colour. The glaze is commonly crackled, and this appears to be fortuitous. Little trouble was taken to achieve a precise finish. Decoration is often of roughly scored vertical flutes, with incised circles at the shoulder to accentuate the form. The latter is particularly common. Decoration of a more definite kind is always incised under the glaze and is usually floral. Flowers are stylized, sometimes with combed lines on the petals. Covered bowls, dishes, ewers, and bottles with two small loop handles at the neck are the most usual forms. Another type of ware has a rather treacly-brown glaze, but the forms are similar. Some well-modeled animals are also found with this glaze. Tiles and bricks with crudely modeled figures in relief can also be seen. These objects are analogous in form and technique to Chinese pottery of the Sung dynasty, and they are generally regarded as being contemporary with the Sung or Yuan period. While poor quality porcelain enameled with Siamese subjects was made in China for export, some small covered jars of a gray porcelaneous ware, summarily decorated with stylized floral and foliate patterns, seem to have been made at Sawankhalok and the date is probably equivalent to that of the early Ming period. These wares were widely exported throughout the East, one of the ports from which they were shipped being Martaban in Burma. As a result the term "Martabani" ware was sometimes used synonymously with "celadon" in the East.

Little is known of wares made in Annam, but some brownish celadons are regarded as likely to have been made there, as well as some small covered jars painted in a poor underglaze blue.

J. ISLAMIC POTTERY OF THE NEAR AND MIDDLE EAST

The Islamic pottery of Syria, Egypt, Mesopotamia, Persia, Afghanistan, and Anatolia occupies an important place in the history of ceramic art. In quality it rivals even the wares of the Far East, and its influence on the development of European ceramics was more profound than that of any other region except China. In China, too, Islamic innovations were adopted while the Islamic potter, in his turn, owes an incalculable debt to the Chinese.

Near and Middle Eastern pottery was at its greatest between the 9th and 13th centuries and its history is closely linked to the fortunes of the caliphate. Each dynasty was surrounded in its capital by a wealthy and beauty-loving court which patronized artists and artisans. When one dynasty fell and another established itself elsewhere it seems that the finest potters emigrated to the new capital carrying with them their special, and often secret, skills. At first the principal centres of manufacture were Baghdad, Al Fustat (Old Cairo), and Samarkand; later they shifted to Raqqa on the Euphrates and to Ray (Rhages) and Kashan, both in northern Iran.

Most of the pottery in our possession has been excavated and consequently is fragmentary. Little made before the 14th century has survived above ground, and tombs, often rich depositories of undamaged wares in other regions of the world, are fruitless because Muslims do not bury pottery with their dead. Only one or two discoveries of undamaged wares have been made: for

example, at Gurgan, Iran, which was looted by the Mongols in 1221, entire specimens were found carefully packed in large earthenware jars. They had probably formed part of the stock of merchants, who buried them and fled before the invaders.

Excavated fragments are often pieced together by dealers, and frequently unrelated fragments are married to make a slightly more complete specimen and false inscriptions are added. The ultraviolet lamp is the finest weapon in the collector's armoury against this kind of chicanery, revealing such additions ruthlessly. As complete and undamaged specimens are such rarities, some sort of restoration must obviously be attempted but the only satisfactory method is to set the fragments into a plaster matrix which repeats the original form. The missing decoration can, of course, be lightly indicated if thought desirable.

Until recently properly controlled excavations have been rare and many Persian and Armenian dealers who carried out excavations were anxious, somewhat naturally, to conceal the source of their finds. Therefore, although names such as Ray, Sultanabad, and so forth have been given to specific groups of ware, it is not always certain that they were made at these places. They are, however, convenient labels, and are entitled to remain unless they can be replaced by something better.

The glaze of much Islamic pottery is iridescent owing to deterioration through burial. In this it resembles Roman and Near Eastern glass. The iridescence sometimes obscures decoration but if the glaze is dampened with a little water, the underlying painting often becomes visible temporarily. A smear of Vaseline usually has a more permanent effect of the same kind. In the case of a badly-obscured glaze in conjunction with serious deterioration it is often best to remove the glaze altogether, but the job is one for an expert and needs both care and skill.

1. Early Period.—There is little pottery of merit from the period of the Omayyad caliphate (661–750). At this time the capital was at Damascus and the chief interest of the pottery lies in its mingled Mediterranean and Middle Eastern derivation; for example, attempts were made to synthesize the formal repetitive style derived from the ancient Babylonian and Assyrian civilizations with naturalistic ornament in the Greco-Roman style. When the Abbasids overthrew the Omayyads and moved the capital to Baghdad the European influence on ornament waned although good use continued to be made of Western techniques, particularly of lead glazes which had been employed by Greek and Roman potters since the 3rd century B.C. The advantage of lead glaze is that, unlike the more brilliant alkaline glazes known to the ancient Egyptians and still sometimes used at the time in Egypt and Syria, it will adhere to ordinary potter's clay. Its disadvantage is that it blurs all but a few underglaze pigments when it is fired, and consequently the palette which can be used beneath it is very restricted.

2. 9th and 10th Centuries.—An event which had a profound effect on the development of Middle Eastern pottery was the presentation of a number of T'ang porcelain bowls to the caliph Harun al-Rashid about A.D. 800 (see *China: T'ang Dynasty*, above). Shortly after this the first fine pottery was produced in Baghdad and elsewhere. Thus it seems possible that it was through the example of the Chinese that ceramics came to be regarded as an artistic medium instead of a purely utilitarian one. This supposition is borne out by the fact that T'ang wares were in great demand and were imported in large quantities after this date: they and early Islamic imitations, particularly of the mottled T'ang glazes, have been found in various parts of Mesopotamia and as far apart as Egypt and eastern Persia. However, unlike their contemporaries in China, Islamic potters aimed primarily at richness of colour and decoration rather than beautiful shapes and textures. Nearly all their pottery is glazed and is painted with elegant, rather stylized, motifs. Floral and foliate ornaments predominate although complex geometrical patterns are also characteristic. In theory there was a religious ban, formulated in the Hadith ("Traditions" of the Prophet), on all representations of animal life, which were thought to encourage idolatry. In practice, particularly in Persia, the limitation was often disregarded except in the decoration of mosques. The animal figures on pot-

tery are spirited and rhythmical while the human ones tend to be stiff, resembling those in contemporary miniatures. Arabic script was commonly and effectively used, both the Neskhī, or running script, and the angular Kufic.

The Islamic potters were responsible for a number of important technical innovations, the most influential of which was possibly the rediscovery of tin enamel in the 9th century A.D. Tin enamel is a lead glaze rendered white and opaque by the addition of stannic oxide, one of the oxides of tin. Coloured pigment can be painted onto the unfired glaze and both are then fixed in one firing. Though tin enamel was first used by the Assyrians and according to some authorities was discovered as early as 1100 B.C., it had fallen into disuse. The Abbasid potters first used it in an attempt to imitate the texture of T'ang wares but soon it became the vehicle for characteristically Middle Eastern decoration. From Mesopotamia and Persia the technique was later taken to Moorish Spain and then to Italy and other parts of Europe where it was employed for a number of important wares—*maiolica*, *faience*, and *delft* (see *European Pottery to the End of the 18th Century*, below). The Chinese occasionally used an opaque white enamel in the 18th century but they never adopted tin glaze.

Like that of tin enameling the technique of lustre painting was perfected (and probably invented) by Islamic potters. Again, like tin enameling, it later passed to Muslim Spain but not to the Far East. Its origin is obscure but it may first have been used in Egypt during the 8th or 9th century for painting on glass. The date at which the technique was extended to pottery is also uncertain; the 9th century is likely although the earliest dated example is a bottle from Ray made in 1179 (now in the British Museum, London). Probably lustre on pottery was first used to cover entire vessels and may have been employed to evade the sumptuary laws laid down in the Hadith which, by proscribing the use of gold and silver vessels, sought to preserve the earlier simplicity of Muslim life. The metallic pigments employed in lustre-work painting were probably silver and copper in combination, although an occasional ruby glint suggests that gold may sometimes have been included. After firing, the painting can be dull yellow, golden brown, or olive, tinged with green or red. The colouring is, in fact, extremely variable, indicating that the results were partly a matter of chance because materials with unknown and differing proportions of impurities were employed. The metals were applied in the form of oxides, finely powdered and mixed with sulfur. They were painted on to a glazed and fired vessel and were themselves fixed by a light firing. Kiln wastage was probably high.

Extensive use was always made of slip. Wares such as the early *Gabri* type of the 11th century and later had a reddish body washed over with white slip. Designs were executed by scratching through the slip to the body beneath (*sgraffito*). On some later specimens the background was cut away to leave a raised design in white slip (the *champlevé* technique) or the design was incised through the white slip as before and then was itself painted with green and brown slips. Yellowish or green lead glazes were used. The usual motifs are large floral forms, animals, and bold inscriptions. *Sgraffito* ware became common throughout the Middle East and appears in Egypt and Syria in the 13th century.

The site of Samarra on the Tigris, where the Abbasids built their summer palaces in the 9th century, is of great importance both to the student of Middle Eastern wares and to the Chinese ceramic historian, for many fragments of Chinese pottery and porcelain have been found there (see *China: T'ang Dynasty*, above). Among the native wares are some made in a buff body decorated in relief under a green glaze; others with monochrome green, white and yellow glazes, or with glazes mottled in imitation of a well-known type of T'ang decoration; and others painted with cobalt blue (perhaps the earliest use of underglaze blue) and further embellished with lustre of various colours. The discovery of lustre painting on a 9th-century site helps to fix the date of its introduction.

3. Samanid Pottery.—To the northeast, beyond the Oxus (modern Amu-Darya) River, the Samanid dynasty (874–999) became practically independent of the caliphate at Baghdad and fostered a national artistic and literary revival. Samanid pottery, which has been found chiefly at Samarkand and Nishapur, differs from the pottery of more westerly regions in technique and style. The best pieces have a reddish body covered with a white, vivid red-brown or purplish-black slip which was then painted and fired under a lead glaze. The function of the slip, besides providing colour, was to prevent the pigments of the painting from running when the lead glaze was applied. The colours used in painting were the same as those of the slips with the addition of yellowish green and browns. The designs often consisted of the angular Kufic characters used in a simple and effective manner or of stylized birds and floral motifs. The shapes were plain—usually either plates or rather shallow bowls—and the total effect is both bold and elegant.

4. Egyptian Pottery of the Islamic period was at its best during the Fatimid dynasty (969–1171). Wares were at first coarser than those of Mesopotamia because of the poor quality of local materials, and the shapes were less refined since Chinese influence was absent. Lustre painting was, nevertheless, excellent in quality. The exact date of its introduction cannot be determined but the middle of the 10th century is probable. A typical feature is the painting on the backs of dishes, a practice derived from Baghdad and later copied by the Moorish potters of Spain. Signed specimens of lustre ware and tin-enameled wares are known, the best coming from a potter named Sa'd.

Toward the end of the period a much whiter type of ware, with a compact body which was given a harder firing, came into use and thereafter became common throughout the Middle East. An important group of wares, popular until the 14th century, has decoration carved and incised into the body and covered with transparent glazes. This type, too, was widespread, and patterns suggest the influence of some of the Sung wares of China decorated in a similar technique.

5. 11th to 13th Century in Mesopotamia and Persia.—In the 11th century the Seljuk Turks overran Persia and Mesopotamia, and their ascendancy lasted until the advent of the Mongols during the 13th century. As the Seljuks had no capital the most flourishing cities during this time were those on the trade routes. In the 12th century very fine pottery was made in the new white body recently developed in Egypt; this was decorated with bold carving, occasional piercing and translucent glaze. Most of these wares are said to have been found at Ray near Teheran where many other beautiful wares have been excavated, although the kiln sites have not yet been discovered, if, indeed, they existed. Wares with a sandy body and a clear glaze were

painted with a golden-brown lustre, often in conjunction with blue. These seem not to have been made after the city was sacked by Genghis Khan in 1220. Especially associated with Ray are examples of *minai* painting of uncommon quality. The *minai* technique, a Persian discovery of the 12th century, was a method of decoration in which enamel colours were painted onto a glazed and fired pot and then fixed by refiring the pot at a comparatively low temperature. The advantage of the process was that many colours which would not have withstood the heat of the first firing could now be used. The technique may perhaps have influenced the rare examples of enamel decoration on late Sung or Yuan wares from Tz'u-Chou although it did not come into common use in China until the early part of the 15th century (see *China: Ming Dynasty*, above).

At Ray the glaze is cream or turquoise, and the palette included blue, turquoise, purple, red, green, and white, with the addition of gold leaf. All these colours, except the blue, are matt in appearance, and the style strongly recalls that of the Persian manuscript illuminations of the 13th century.

Another technique employed at Ray was the use of silhouette decoration. The pot was covered with a thick black, or blue and black, slip and the design was carved out with a knife. The glazes were applied without colour or stained with copper to yield a brilliant turquoise.

Raqqaq was a prosperous trading city until it was sacked by the Mongols in 1259. Most of its pottery, which can be dated between the 9th and 14th centuries, is rougher, and the designs bolder than those of Ray. The body is white, inclining to buff, and is covered with a siliceous glaze. Some of the Raqqaq fragments are painted with a brownish lustre. Others have designs in relief, sometimes covered with an opaque turquoise glaze, or with a bluish-green translucent glaze. In the 12th and early 13th centuries bold designs were executed in underglaze black with pale blue glazes and more frequently in blue and black under a clear glaze. Occasionally the glazes were stained purple with manganese. Like the Egyptian wares in the same style, but unlike those of Ray, the slips used were fluid enough to be applied with a brush.

Kashan is chiefly famous for its tiles, in fact the words *kashi* or *kashani* ("of Kashan") are commonly used as a synonym for tile (and have been incorrectly applied to tilework from India). Lustre painted tiles had been made since at least the 9th century and were used mostly on the walls of mosques and public buildings. Those of Kashan, particularly in the 13th and 14th centuries, are distinguished by their fine workmanship, brilliance, and intricacy of design. In shape they are square, rectangular, or interlocking cross or star shapes, each carrying a small part of the total design. The relief inscriptions are frequently picked out with blue pigment.

Also associated with Kashan are the *lakabi* ("painted") wares made in the 12th century. The term, a misnomer, refers to a variation of the *sgraffito* technique mentioned above: an incised design was decorated with different coloured glazes which were kept apart by the intervening threads of clay. The colours used were blue, yellow, purple, and green. Although a number of *lakabi* wares were also made at Raqqaq, the technique was soon abandoned at both places as the glazes always tended to run out of their compartments during firing, giving a smudged effect.

Both the site of Sultanabad and the nature of the wares which may have been made there are extremely uncertain. The modern town is situated on the road between Hamadan and Isfahan. Principally associated with it are wares decorated with relief moulding under a turquoise or dark blue glaze, or painted in black slip under a clear turquoise glaze. They date from the second half of the 13th century onward. Toward the end of the 12th century the glaze material was frequently mixed with the white-burning clay when in use. In the more highly fired specimens the product is not unlike a primitive soft porcelain, and occasional specimens are slightly translucent. Although this was undoubtedly an attempt to reproduce the porcelain of the Chinese, it is doubtful whether the translucency was ever more than the result of accidental aggregations of glassy substances. These wares probably inspired the attempts to make porcelain at Florence (see

European Porcelain, below). Neither stoneware nor true porcelain was ever made in Persia.

6. Later Persian Pottery.—After the Mongol conquests of the 13th century the production of pottery practically ceased except at Kashan. A slow revival began about 1295 and although pottery in the Near and Middle East never again reached its former height, some fine wares were made at Sultanabad in the 14th century. Good use was made of the rich sombre colours beloved by the Mongols, particularly dark blues, grays, and blacks.

Since the whole of Central Asia now lay under the Mongol domination, overland trade with China greatly increased and by the 15th century Chinese influence, particularly that of Ming blue and white, was predominant, and the older styles were tending to die out. A group of blue-and-white wares belonging to the 15th and early 16th century are known as "Kubachi" wares because large numbers of them survived above ground in this town in the Caucasus; their place of manufacture remains uncertain. They have a very soft body, a brilliant crackled glaze, and are notable for the rhythmical and spontaneous qualities of their design. The later "Kubachi" blue and white is closer to the Chinese originals. Polychrome appears about 1550 and the palette includes a red, related to, though lighter than, the Armenian bole introduced about the same time in Turkey (see *Turkish Pottery*, below). The best polychrome painting was done on tiles. Tabriz has been suggested as the real centre of manufacture, but although it seems likely that Tabriz was a manufacturing town, in view of its tiled mosques and the fact that Tabriz potters were famous abroad (and indeed were either invited or carried off to Turkey on two occasions), no kiln sites have been found there.

The location of later kiln sites in Persia is equally uncertain, one of the few known ones being Kerman, which was the leading pottery centre in the 17th century. Its wares are characterized by a very strong bright blue and a wavy, rather bubbly, glaze. Pseudo-Chinese marks were frequently added to the blue and white. The most usual colours on Kerman polychrome wares are blue, green, browns, and a bright red similar to Armenian bole. The quality of production declined considerably during the 18th century.

Lustre painting was revived during the second half of the 17th century and perhaps lasted into the 18th century. Its place of manufacture is not known. Most of the objects decorated in this manner are small bottles or spittoons and their cramped designs are timid and fussy. The lustre is warm brown, often with a strong red tinge, and was sometimes used in conjunction with blue glaze. Another early technique revived at the same time was that of piercing, formerly practised in the Seljuk era. There are a number of delicate pierced white wares covered with a colourless glaze, which were imitated in China during the reign of Ch'ien-lung. Persian pottery of this period was often known in Europe as Gombroon ware, the name of the port (now Bender 'Abbas) from whence it was shipped.

Chinese celadon was imitated, not very successfully, from the 14th century. In the 16th century other monochrome glazes were produced at Kerman and elsewhere. These and the celadon were frequently decorated with painted or incised ornament—a practice quite foreign to the Chinese style.

During the 18th century most of the pottery produced in Persia was inferior blue and white. In the 19th century the standard declined still further with the adoption of the *famille rose* palette, and only a group of wares made at Teheran between 1860 and 1890 can command any respect. Some excellent peasant pottery with a buff body and lead glaze was made in Turkistan.

7. Syrian Pottery.—The potters from Al Fustat and Raqqa may have migrated to Damascus after their potteries were destroyed, for lustre painting continued in Syria throughout the 13th and 14th centuries when it had ceased elsewhere in the Middle East. The lustre ranges in colour from silver to yellow and dull brown and is often used in conjunction with a blue glaze on big, heavy jars and albarelli. Characteristic are gold designs arranged in panels with much use of inscriptions and heraldic devices. The body material is coarse and grayish and the glaze sometimes has a wide crackle. Lustre painting fell into disuse in Syria about 1400 and might have died out altogether had not the secret meantime been carried from Egypt to Spain (see *European Pottery to the End of the 18th Century*, below). The commonest type of Syrian pottery in the 14th century is a blue-and-black style similar in shape and design to the lustre ware. Rather uncertainly drawn animals appear on some of the vessels.

The earliest-known Middle Eastern copies of Chinese blue and white were made in Syria and can be assigned with certainty to the end of the 14th century. (This has helped to date the introduction of blue and white in China.) Blue and white became commoner on both vessels and tiles in the first half of the next century. Later the potteries seem to have fallen into disuse until the new mosque built in Damascus by Suleiman I in the mid-16th century provided a fresh impetus for the industry. The polychrome tiles of the 16th century have at first designs with a hard black outline; later a more flowing foliate style was developed. A soft purple replaces the Armenian bole of Iznik (see *Turkish Pottery*, below). Vessels and tiles, gradually declining in quality, continued to be made in Damascus till the end of the 18th century.

8. Turkish Pottery.—A branch of the Seljuk Turks occupied Anatolia from 1078 to 1300 and was succeeded by the Ottoman Turks who first extended their lands westward, conquering Byzantium in 1453 and in the 16th century became masters of much of southeastern Europe and the lands lying to the east and south of the Mediterranean. The first notable ceramics from Turkish lands were the tiles and bricks covered with coloured glazes made in Anatolia for architectural purposes in the 13th century. Mosques in particular were decorated in this way and Persian influence in decoration suggests the presence of potters from that region. The art of tile mosaic apparently died out after 1300 and was not re-introduced until about 1415 when Persian craftsmen were brought from Tabriz to decorate the mosques at Bursa and Edirne. Apart from tilework, pottery appears to have received little encouragement until the late 15th century by which time the chief centre of production was firmly established at Iznik (earlier called Nicaea). Iznik was selected because of deposits of suitable clay in the neighbourhood, and there may have been potteries here, and at Ismi not far away, as early as the 12th century.

The great era of Turkish pottery (c. 1500–c. 1580) coincides with the expansion of Ottoman power. Decoration was strongly influenced by 15th-century Ming blue-and-white porcelain. The earlier designs were probably taken at second hand from Persian sources, since a distinctly Persian flavour is usually evident. Their intricacy and minuteness, their arrangement in bands, and the shapes of some of the vessels all indicate the influence of metalwork. At one time the wares in this style, which lasted until about 1525, were thought to come from Kutahiya in central Anatolia and are still sometimes known by that name.

At this and later periods the body of Iznik pottery was soft and sandy. It was made from grayish-white clay covered with a thin slip which was usually white, although occasionally red or blue

was used on later wares. Decoration was carried out in high temperature colours under a transparent siliceous glaze. The commonest shapes are flat dishes, but jugs, dishes with a high foot, and bowls are also found. Cylindrical vessels with small rectangular handles set halfway down are flower vases not tankards. A rare form is a pottery version of a mosque lamp. A number of dated pieces exist.

During the next period (c. 1525–50), whose wares have been erroneously attributed to Damascus, Iznik pottery was at its finest. Ming blue and white was now copied directly; for example, the central motif of grapes to be seen on a dish in the Victoria and Albert Museum in an almost exact imitation of a well-known and mid-15th century Chinese motif. (It is interesting to note that somewhat similar patterns of grapes appear on the back of bronze mirrors of the T'ang period, and also on some Roman mirrors in the same material.) On the same dish can be seen a characteristic border pattern which was called the "Ammonite" scroll border since it was thought to resemble the coiled shell of the fossil ammonite but which is certainly a debased version of the Ming "Rock of Ages" pattern. This scroll border appears often; a slightly later version, which incorporates large "S"-shaped scrolls and is sometimes known as the "dollar" pattern, would be difficult to recognize as derived from the "Rock of Ages" border without knowledge of the intervening stage.

The palette was gradually expanded to include turquoise, sage green, olive green, purple, and black. Most of the blue and turquoise specimens are painted with flowers. The Chinese floral motifs tended to be replaced by tulips, poppies, carnations, roses, hyacinths, and cypresses which appeared in the form of fairly symmetrical sprays springing from a single point. The earliest flowers are often rather more stylized than the later, perhaps because the representation of living things was prohibited by Koranic tradition. Even on comparatively late examples, floral designs are sometimes stylized to the point of abstraction, and it is possible that decorators suited their patterns to the religious susceptibilities of their customers. An effective abstract pattern is formed from a series of overlapping scales which are usually carefully drawn. The same ground was later imitated in Italy on *maiolica*, and may have indirectly inspired the series of wares with scale grounds made at Worcester, Eng. The latter factory probably took the idea from certain Meissen and Berlin *mosaik* patterns, and it is noteworthy that a faience factory in Berlin copied the work of Iznik. This is an excellent example of the transfer of ideas, often by indirect routes, from one place to another. Trading connections with Turkey at the end of the 16th century were well established and we find examples of Iznik pottery with contemporary English silver mounts.

After about 1550 Iznik pottery enters its third stage. The most notable technical innovation is the use of Armenian bole ("sealing-wax" red), a thick pigment which stands out in slight relief from the surface of the vessel.

The other great change is that tiles which had previously

been made in small numbers, became all important until the early 17th century. They were used to provide lavish decoration for the new mosques built at Istanbul by Suleiman I the Magnificent (1520–66). Once again potters were brought from Tabriz to begin the work. Much use is made of copper green and the new red, the colours appearing very brilliant on the glossy white ground. The tiles, usually square, make up flowing repeating patterns or long high pictures with elaborate borders.

On pottery symmetrical sprays of flowers continued to be used as decoration until about 1600. Paintings of animals and birds are found occasionally and were probably executed by Persian workmen since their resemblance to Persian wares is strong. The rare specimens with human figures were probably painted by Greeks or Armenians for export to the West. Turkish sailing vessels sometimes appear and are an effective decorative motif.

In the 17th century the quality of Iznik wares declined and manufacture had ceased by 1800. At Kutahiya pottery making had begun by 1608 and continued into the middle of the 20th century. The wares, though inferior, have some resemblance to those of Iznik with the addition of a yellow pigment.

K. EUROPEAN POTTERY TO THE END OF THE 18TH CENTURY

The wares made in Europe before the 19th century fall into three main categories: lead-glazed earthenware, tin-enameled earthenware, and stoneware.

Lead-glazed earthenware was made from medieval times onward and owes little to outside influences. The body is generally reddish buff in colour and the glazes are coloured yellow and brown from iron compounds, purplish from manganese, or green from copper. The wares are usually vigorous in form but are often crudely finished. Lead-glazed wares fell out of favour when tin glaze became widely known toward the end of the 15th century, but they returned to popularity nearly 300 years later. The body of this later earthenware is white or cream in colour, the glaze is clear and transparent like glass, and the forms are precise.

The first important tin-enameled wares came from Italy during the Renaissance, and these colourful examples of the painter's art exerted a profound influence on later work elsewhere. Manufacture spread rapidly, first to France, then to Germany, Holland, England, and Scandinavia. Under the name of *maiolica*, faience, or delft it enjoyed immense popularity until the advent of Wedgwood's creamware shortly after the middle of the 18th century, after which the fashion for tin-enameled ware declined rapidly.

Stoneware is first to be seen in Germany during the 16th century; its manufacture was developed in England during the 18th century, culminating in the unglazed ornamental jaspers and balsates of Wedgwood.

Two other types of ware, less common than these already discussed, are slipware and lustre ware. Slip was applied both as a covering over an earthenware body and in the form of decorative for example on the *sgraffito* wares of Italy (which owe a good deal to similar wares from Byzantium) and the dotted and trailed slips of 17th- and 18th-century England. Lustre pigments were used in Spain, where they are the principal decoration on the magnificent series of wares referred to as Hispano-Moresque; in Italy, where they supplement other modes of decoration; and much later, in England—although in the last case they are no longer artistically important.

1. Byzantium.—In A.D. 330 Byzantium became the imperial capital of the Roman Empire and was renamed Constantinople. The term Byzantine, however, is applied to the period which ended only in 1453 when Constantinople was captured by the Ottoman Turks (since when the city has been known as Istanbul).

It was not a Christian custom to bury pottery with their dead and in consequence few wares survive and chronology is difficult. Most of the surviving wares fall into two classes: one is a red-bodied type, sometimes with stamped relief decoration under a clear glaze; the other, a *sgraffito* type with human figures, animals, birds, monograms, foliate designs, the Greek cross, and the like engraved through a white slip and covered with yellow and green glazes. The latter is the commonest technique after the 12th century. Both styles were fairly widespread, and have been recovered

in fragmentary form from excavations at Istanbul, and in Greece, Cyprus, and the Crimea.

2. *Spain*.—The wares of Spain can be divided into two classes: lustred pottery and tin-enameled wares.

Lustre Ware.—The lustre technique spread to Moorish Spain by way of Egypt, but it is impossible to say exactly when it arrived.

The body of Hispano-Moresque pottery is usually of fairly coarse clay, which has burned to a pinkish buff, covered with a tin enamel containing lead in varying proportions. The lustre, added overglaze, varies in colour from golden to a pale straw, and a coppery lustre almost invariably indicates at least a 17th-century date. Many dishes were also painted in blue and, less often, with manganese.

Most surviving wares of the early period are dishes of various shapes. Less often seen are *albarelli*, waisted drug jars which were based on a Middle Eastern form. Vases based on the old Iberian *amphora* but with two massive wing handles are very rare; a superb specimen (the Alhambra vase) is in the Museo Español de Antigüedades in Madrid. The decoration is predominantly Moorish on early examples, but specimens of this kind are unlikely to be later than 1525. Subsequently, Spanish artists repeated the Moorish designs but they often degenerate in their hands and the Kufic script, frequently used by Moorish potters, becomes meaningless. The early designs are, for the most part, plant forms and arabesques, both the vine leaf and the bryony leaf being used. A little later we find magnificently drawn animals in heraldic form, principally lions and eagles. The deer and the antelope, which may owe something to Persian sources, are still later. Dishes with coats of arms of noble families surrounded by vine- and bryony-leaf ornament are not only unusually fine but are of some assistance in dating in cases where the arms can be traced. Many of them were made in and around Valencia for Italian families. A feature of many of the dishes is the lustre decoration on the reverse. Although often no more than a series of concentric circles, the superb eagles and other animals occasionally found on dishes from Valencia are even finer than the obverse designs, and are drawn with great economy by a sure hand.

It is not always easy to say where pieces of lustre ware were made. Málaga was probably working until the beginning of the 16th century, but after this the principal centre was Valencia and its suburb of Manises. Valencian pottery was particularly popular in Italy (see below).

In the 17th century much lustred pottery was made for the cheaper markets. The painting is executed in a lustre pigment of deep coppery hue, and while this ware is not important in comparison with the early wares, it is often decorative. It was freely exported to England, and fragments dredged from Bristol docks once caused it to be attributed mistakenly to potteries in that city.

Other Tin-Enameled Ware.—Although the influence of lustre pottery on later Italian *maiolica* is obvious, the wares of Paterna, near Valencia, were hardly less influential in the 14th century. They were decorated in green and manganese, often with motifs taken from Moorish sources, and this combination of colours is to be seen in early Italian pottery from Orvieto and elsewhere.

Much tin-glazed pottery of excellent quality was made at Talavera de la Reina, in New Castile, during the 17th and 18th cen-

turies. The palette is characteristic; green and manganese again play a distinctive part, frequently combined with touches of orange-red and gray. The *istoriato* style of Urbino, discussed in the next section, was copied here, and the Italian painter and engraver Antonio Tempesta (1555–1630) provided a source of inspiration for some of the painting. Alcora, in Valencia, made much faience of excellent quality during the 18th century and used designs after Jean Bérain (1637–1711) in the manner of the French factory at Moustiers (properly Moustiers-Sainte-Marie). Later it produced some cream-coloured earthenware in the style of Wedgwood.

Tilework was particularly common in Spain from the earliest period and, according to one proverb, only a really poor man had "a house without tiles." At first the tiles were made with a typically Persian technique in which thin slabs of tin-glazed pottery were sawed into pieces and embedded in a kind of mortar (tile mosaic). The *cuerda seca* method followed about 1500: outlines were drawn on the tile in manganese mixed with a greasy substance which prevented the coloured glazes used from mingling. Tiles made by the *cuenca* technique had deeply impressed patterns whose compartments were filled up with coloured glazes. Tiles were also decorated with lustre pigments.

3. *Italy*.—The pottery of Italy is extremely important not only in itself but for its subsequent influence on production in other European countries. Indeed, its influence may have spread even farther afield, because a few specimens of Ming porcelain have motifs which may have been inspired by it.

There are two well-defined classes of Italian wares: *maiolica*, or tin-enameled ware, and pottery decorated in the *sgrafitto* technique, sometimes called *mezza-maiolica*.

Maiolica.—Tin enameling was introduced from the Middle East through the Muslim civilization in southern Spain, wares being shipped from there to Italy by Majorcan traders. The term *maiolica* was at first applied to this Hispano-Moresque lustre ware, but in the 16th century it came to denote all tin-enameled ware.

Italian *maiolica* is principally noteworthy for its painted decoration, which excelled in technical competence anything which had been produced in Europe since classical times. It was often called Raffaele ware, a tribute to the influence of the painter Raphael (1483–1520) although he, in fact, never made any designs for pottery. In particular the *maiolica* painters copied his *groteschi* motifs adapted from those on imperial classical ruins (principally the *thermae* ["baths"] of Titus and the Golden House of Nero) and so named because they were first rediscovered in the grottoes there. They are usually fantastic combinations of human, animal, and plant forms.

Much of the technical information about Italian pottery comes from a manuscript written c. 1548 by Cipriano Piccolpasso (1524–79) of Castel Durante, in the province of Pesaro e Urbino; it is entitled *Le tre libri dell'Arte del Vasaio*, and the author discusses such questions as the preparation of the clay, the glazes and the colours, as well as methods of applying the last two. The painting was executed in high-temperature colours on the dry but unfired enamel glaze. Great skill was needed since the surface absorbed the colour like blotting paper absorbs ink and erasures were therefore impossible. The best wares were given a final coating of lead glaze, called *coperta*. The range of colours was comparatively limited: cobalt blue, copper green, manganese purple, antimony yellow, and iron red formed the basic palette, while white was provided by the glaze material. The use of white can be seen in examples painted in this colour on a bluish-white glaze (*bianco sopra bianco*, or "white on white"), or on a light blue ground (*berettino*). A dark blue ground was used in the same way.

Lustre pigments were introduced from Spain and were used for a short time on wares made at Cafaggiolo in Tuscany, and in two Umbrian towns, Gubbio, where the best-known painter was Maestro Giorgio Andreoli (c. 1462–c. 1553), and Deruta. The lustre is often the golden yellow colour derived from silver, but the ruby lustre of Andreoli suggests the use of gold. The silver lustre often developed a nacreous effect known as *madre perle* ("mother-of-pearl").

Forms are few and comparatively simple. For the most part

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

HISPANO-MOESQUE WARE

Spanish *albarello* (drug jar) painted with lustre on a blue ground; Valencia, about 1460. Height: 10½ in. In the British Museum

they were dictated by the necessity for providing a surface on which the painter could exercise his skill and for this reason dishes form the greater part of surviving wares. It is doubtful whether most *maiolica* was ever intended for general use. Dishes, for instance, were displayed on sideboards and buffets far more often than they were placed on the table. Gaily coloured drug jars were a fashionable decoration for pharmacies and include the albarellio shape for dry drugs, copied from Spain, and a spouted jar for wet drugs. Ewers with a trefoil spout, derived from the Greek *oenechoe*, were made as well as massive jars represented by Florentine work of the 15th century.

The earliest *maiolica* is decorated in green and manganese purple in imitation of the Paterna ware mentioned above. Much work of this kind was done at Orvieto, in Umbria, and jugs with a disproportionately large pouring lip are characteristic. "Orvieto" ware has almost become a generic term for anything in this style although similar vessels were made at Florence, Siena, and elsewhere. It was current in the 14th century and continued in the 15th century, when other colours were added to the palette. The decorative motifs are Gothic, with some traces of Eastern influence.

Also from Florence came a series of wares painted in a dark, inky, *impasto* (or "very thick") blue. These, too, have Gothic ornament, particularly oak leaves which came into use sometime before 1450. Heraldic animals also appear on some specimens. This kind of decoration was obviously inspired by Spanish pottery and a few examples are hardly more than copies. Soon after 1500 Florentine production was concentrated in the castle of Cafaggiolo and came under the patronage of the Medici family, whose arms appear frequently. A notable addition to the palette here was a bright red pigment, a most difficult colour to attain and one which was not often used.

Gothic ornament was gradually displaced by classical motifs such as arabesques, trophies, and the like, which themselves gave way to the *istoriato* style. This style, no doubt inspired by the achievements of contemporary painting, imitates the easel picture closely. Its realism, including the use of perspective, is quite unlike any previous ceramic decoration. The subjects were often classical, but biblical subjects, some taken from the woodcuts of Bernard Salomon (c. 1506-61), are frequently represented. The works of Raphael, Dürer, and Andrea Mantegna were also borrowed, often through engravings made by Jacopo Ripanda (Jacopo da Bologna; d. c. 1530) and Marcantonio Raimondi (d. c. 1534); some specimens are almost exact copies, others are freer interpretations. The paintings sometimes occupy the centre of the dish with a border of formal ornament surrounding them but in many instances, notably those from Urbino, they cover the entire surface. It is often impossible to regard the pottery body as anything more than a surface for the painting, its pictorial or narrative subject having been executed with little or no consideration for the nature of the object it decorated. Although ceramic decoration is rarely successful unless it is designed to en-

hance, or at least not to detract from, the shape of the body, an exception must be made for some of these colourful wares: at their best they are highly ornamental.

The *istoriato* style probably developed about 1500 at Faenza (Emilia), one of the earliest and most important centres which had been manufacturing *maiolica* since before 1450. Almost as early are some examples from Cafaggiolo. Castel Durante adopted the same style, where it is particularly associated with the name of Nicola Pellipario (d. c. 1542), the greatest of the *maiolica* painters. He also painted grotesques similar to those of Deruta and elsewhere; these are rather more stylized than the grotesques introduced later in the 16th century at Urbino, which was probably the largest centre for the manufacture of *maiolica* at the time. Many wares from Urbino have survived. The industry there was under the patronage of the Della Rovere family, whose name, meaning "oak tree," led to the adoption of the oak-leaf motif in wreathed form. The later Urbino grotesques are in a humorous vein, and full of movement. They are often used as a surround to an interior medallion in the *istoriato* style.

Among the early factories, that of Deruta is of considerable importance and may have been under the patronage of Cesare Borgia. *Maiolica* has been made there from medieval times and manufacture continues in the mid-20th century. Deruta potters were the first to use lustre pigment, which was of a pale yellow tone, and they also adopted the Spanish practice of painting designs on the reverse of dishes. They covered only the obverse with tin-enamel, and applied a lead glaze to the reverse—again, a typically Spanish practice. The best work was done before 1540.

The use of lustre pigments at Gubbio probably started soon after it began at Deruta, and the quality of the work was such that *maiolica* was sent from Castel Durante, Faenza, and even from Deruta itself for this additional embellishment.

An interesting series of dishes is that painted with the portraits of young women, often with the addition of a terse and appreciative comment, such as "*Bella*."

Maiolica was manufactured in Venice between the 16th and 18th centuries. As might be expected in an important seaport with worldwide trade, its *maiolica* often shows Eastern influence. The designs of Iznik were sometimes copied (as they were, in fact, on other Italian wares of the period) and imitations of Chinese porcelain of the Ming period gave rise to a style known as *alla porcellana* ("in the manner of porcelain").

Of the later potteries, that of Castelli, near Naples, did excellent work from the 16th century onward, although its wares tend to become pedestrian. *Istoriato* painting was revived there in the 17th century in a palette which is paler in tone than that of early work in this style. Much *maiolica* survives from Savona, in Liguria region, a good deal of which is painted in blue in Oriental styles. There were also many small centres during the 16th and 17th centuries whose work can hardly be identified. Many of them copied better-known wares with varying success.

Sgraffito Wares.—These are comparatively rare. The technique was derived from Byzantine sources by way of Cyprus, which was under Venetian rule from 1472 to 1570. Manufacture was confined to northern Italy, the largest centre being at Bologna. The body was covered with a slip of contrasting colour, the decoration then being scratched through to the body beneath and the whole covered with a lead glaze. Often the incised designs were first embellished with high-temperature colours (blue, green, purple, brown, and yellow), which tended to run during firing. The lead glaze has a yellowish tone. The manufacture of these wares died out finally at the end of 18th century, but some important work of the kind was done in the late 15th and 16th centuries.

Later Wares.—A number of factories were founded during the 18th century, but the distinctive style of the earlier wares can no longer be seen. A factory in Turin, for instance, imitated the work of Moustiers, and the Rococo style was generally adopted.

Forgeries.—Forgeries of Italian *maiolica* of the best period are fairly common, and many European factories tried to imitate it during the 19th century when it was especially popular. The work of Urbino, Castel Durante, Faenza, and Gubbio was copied freely, and, to a lesser extent, the wares of Orvieto and Florence received

similar attention. Most are not particularly deceptive to anyone acquainted with genuine examples.

4. **France and Belgium.**—The medieval pottery of France is difficult to date and classify with accuracy, but the lead glaze was in common use by the 13th century at the latest. Some examples, especially those with yellow and green glazes, are reminiscent of English pottery of the same period, and the knowledge of glazing probably reached England from France. Proficient *sgraffito* decoration was done at Beauvaisis (Oise) and at La Chapelle-aux-Pots (Charente-Inferieur).

Lead-Glazed Wares of the 16th Century.—Bernard Palissy (*q.v.*) began to experiment with coloured glazes about 1539 and, after much difficulty, succeeded in producing his "rustic" wares in 1548. For the most part these are large dishes made with wavy centres intended to represent a stream, with realistically modeled lizards, snakes, and insects such as dragonflies grouped thereon. They are decorated on the obverse with blue, green, manganese purple, and brown glazes of excellent quality, while the back is covered with a glaze mottled in brown, blue, and purple. Palissy later turned his attention to classical and biblical subjects which he molded in relief. After his death in 1589, work in his style was continued at the Avon pottery, near Fontainebleau.

Almost contemporary with Palissy's rustic ware is a type of pottery which was made in the style of the metalwork of the period. It was made at Saint-Porchaire and is sometimes called,

16TH-CENTURY FRENCH LEAD GLAZED WARES

(Above) "La Fécondité," dish by Bernard Palissy; about 1580. Length: 19 in. (Right) Candlestick made at Saint-Porchaire, sometimes erroneously called *Henri Deux* ware; about 1540. Height: 13 in. In the Victoria and Albert Museum

erroneously, *Henri Deux* ware, or *faïence d'Oiron*. The body is ivory white, and covered with a thin glaze. Before firing, designs were impressed into the clay with metal stamps like those used by bookbinders, and the impressions were then filled with slips of contrasting colours. This technique resembles the *mishima* mode of decoration in Korea.

Faïence, or Tin-Enamelled, Ware.—This dates from the early part of the 16th century. The art of tin enameling was learned from Italy, the wares of which were much admired. Italian potters were established at Lyons in 1512 and attributions, at one time controversial, were confirmed when a dish inscribed "Lyon 1582," was discovered in 1959 (now in the British Museum, London). By the end of the 16th century, painting in the manner of Urbino was well established there. Faïence, the designs of which were influenced by Italian *maiolica*, was also made at Rouen, probably as early as 1526, and Nevers started work toward the end of the 16th century.

A new factory was established at Rouen about 1656 by Edmé Poterat, probably assisted by workmen from Nevers. Edmé's son, Louis, introduced a decoration of *lambrequins*, ornament with a jagged or scalloped outline based on drapery, scrollwork, lacework ornament, and the like, which was used in much the same way as the German *Laub- und Bandelwerk*. *Lambrequins* were extremely popular and were copied at other porcelain and

dishes decorated with designs after Jean Bérain (1637–1711) whose work greatly influenced French decorative art at the time. These designs usually include grotesques, *baldacchini* ("canopies"), vases of flowers, and the like, linked together by strapwork in a typically Baroque manner.

In 1709, when Louis XIV and his court melted down their silver to help pay for the War of the Spanish Succession, the nobility looked for a less expensive medium to replace it. In consequence faïence gained in popularity and importance. A great deal was manufactured in the region of Marseilles, the factory of the Veuve Perrin being particularly noted for enamel painting in the Rococo style, but perhaps the most influential factory was that of Strasbourg, in Alsace (which had officially become part of France in 1697). The factory here was started by C. F. Hannong in 1709, and the wares painted in blue, in other faïence colours and in enamel colours, were much copied elsewhere. The latter were introduced about 1740, the first recorded use in France of tin-enamelled pottery. Brilliant *indianische Blumen* (flower motifs which were really Chinese in origin but which were thought to be Indian because they were imported by the East India companies) were painted in a palette which included a carmine similar to the "purple of Cassius," the Chinese *rose* enamel. A characteristic copper green was also used. *Deutsche Blumen* ("German flowers") were introduced, perhaps by A. F. von Löwenfinck, about 1750, and inspired similar painting elsewhere. Figures by J. W. Lanz, who also worked in porcelain here and at Frankenthal, are to be seen. Much work was done in the fashionable Rococo style, including objects such as clock cases, wall cisterns, and tureens in the form of fruit and vegetables. Both faïence and porcelain in a variety of decorative forms were used for the banqueting table and, in Germany, it was the custom to serve dessert at a separate table also decorated in this way.

The wares of Niderviller, in Lorraine, were much influenced by those of Strasbourg. The earlier figures are reminiscent of those of Lanz. The later ones were probably modeled by the sculptor Charles Gabriel Sauvage, called Lemire (1741–1827), and were sometimes taken from models by Paul Louis Cyfflé (1724–1806). At Lunéville, not far away, Cyfflé worked in a pleasant but sentimental vein,

faïence factories. The faïence of Nevers, too, is extremely important, and shows the Baroque style at its best. In the second half of the 17th century the porcelain of both China and Japan became increasingly well known in Europe, and many designs were borrowed from Chinese sources by potters at Nevers and elsewhere.

The factory of Moustiers in the Basses-Alpes was founded by Pierre Clérissy in 1679. During the early period frequent use was made of the engravings of Antonio Tempesta (1555–1630) as well as biblical scenes. Later came a series of

dishes decorated with designs after Jean Bérain (1637–1711) whose work greatly influenced French decorative art at the time. These designs usually include grotesques, *baldacchini* ("canopies"), vases of flowers, and the like, linked together by strapwork in a typically Baroque manner.

and used a semiporcelain biscuit body known as *terre-de-Lorraine*, which was intended to resemble the biscuit porcelain of Sévres. He was later copied by modelers in Staffordshire, notably Jean Voyez. The work of both Sauvage and Cyfflé is extremely skilful.

Faïence was made at Tournai (now in Belgium) and at Brussels during the 17th century. Their styles were mainly derivative, but Brussels made some excellent tureens in the form of poultry, vegetables, fruits, and so forth during the Rococo period.

Only some of the more important factories have been mentioned since the number operating during the 18th century was very large. The products of the smaller centres were mostly based on the wares discussed above, and in some cases were merely copies. Porcelain, too, affected the decoration of faïence, not only in the adoption of enamel colours (as at Strasbourg and Marseilles) but much more directly, as in some of the work at Sceaux, which is some 5 mi. S of Paris. Wedgwood's creamware was imitated at many of the French factories toward the end of the 18th century, and Apt, in Vaucluse, made an excellent agateware, as well as lead-glazed pottery modeled on contemporary silver. After 1800 there was a distinct tendency to concentrate on the manufacture of porcelain.

5. Germany and Austria.—While Germany is principally noted for its superb porcelain (described in the section *European Porcelain*, below), the stoneware of the Rhineland is, in its own way, no less noteworthy. A great deal of faïence was also made though this was less important.

Hafner Ware.—The earliest type of ware made in Germany was the *Hafnergeschirr* (*Hafner*, "stovemaker"; *geschirr*, "vessel"). Originally the term referred to tiles, molded in relief and usually covered with a green glaze, which were built up into the large and elaborate stoves needed to make the mid-European winter tolerable. Jugs and other vessels made by these stovemakers, however, came to be called Hafner ware by extension when their manufacture began about the mid-16th century. The work of Paul Preuning of Nürnberg is an example of this kind of ware. He decorated his pottery with coloured glazes kept apart by threads of clay. In Silesian Hafner ware, on the other hand, the design is cut out with a knife and the incisions prevent the coloured glazes from mingling. The earliest German stove tiles date back to about 1350, and are lead glazed. Tin glazes came into use about 1500.

After these beginnings, German pottery developed in two distinct classes: stoneware and tin-enameled earthenware.

Stoneware.—The stoneware (*Steinzeug*) came mainly from the Rhineland, and in particular from Cologne, Westerwald, Siegburg, and Raeren (the latter now in Belgium). Manufacture probably began in Cologne about 1540. The body is extremely hard, and varies from almost white (Siegburg) to bluish gray (Westerwald), while a brown glaze over a drab body is also to be seen (Raeren). The surface was glazed with salt and was no more than a "smear" glaze, pitted slightly like orange peel. A smooth, though still very thin, glaze was achieved by mixing the salt with red lead. Particularly popular at Cologne in the late 16th century was the *Bartmannkrug* ("bearded-man jug"), a round-bellied jug with the mask of a bearded man applied in relief to the neck. This type was sometimes called a "Bellarmine," the mask being regarded as a satire on the hated Cardinal Robert Bellarmine (Bellarmino), but there is no authority for this assumption. In England, where they were imported in large quantities, they were also known as "graybeards." A mottled brown glaze over the grayish body was common and gave rise to a second term, "tigerware."

Some of the earliest German stoneware is notable for its remarkably fine molded decoration in the Gothic style. Oak-leaf and vine-leaf motifs were common, as were coats of arms on medallions. The applied relief and stamped decoration was, at times, most elaborate and the thin glaze lent it additional sharpness and clarity. Reliefs of biblical subjects appear on tall, tapering tankards (*Schnellen*), which were provided with pewter or silver mounts. The *Doppelfrieskrüge* were, as the name implies, jugs with two molded friezes round the middle; they usually portray classical subjects. They and the *Schnellen* were made in Raeren

brownware by Jan Emens, surnamed Mennicken, in the last quarter of the 16th century. Emens also worked in the gray body which was used at Raeren at the turn of the century, in this case employing blue pigment to enhance the decoration. Figures were sometimes set in a frame reminiscent of Gothic architectural arcades, and inscriptions of one kind or another are fairly frequent. A few signed and dated examples are known. At a later date, blue and manganese pigments were used together and this practice continued throughout the 17th century.

The style of the stonewares gradually fell into line with the prevailing Baroque style, particularly toward the end of the 17th century. At Kreussen, in Bavaria, a grayish-red stoneware was covered with a brown glaze and the molded decoration was picked out with opaque overglaze colours which had a tin-enameled base. This was the first time enamel colours had been used on pottery in Europe. The technique, learned from Bohemian glass enameleurs, was to have some influence in France as well as Germany.

German stoneware was extremely popular abroad; during the 17th century, for instance, Siegburg even exported to Japan.

An extremely important type of stoneware was first made shortly before 1710 at Meissen, in Saxony. It was discovered by E. W. von Tschirnhaus (1651–1708) and J. F. Böttger (1682–1719) during their researches into the secret of porcelain manufacture. It usually varies from red to dark brown in colour, due to the presence of iron oxide, and is the hardest substance of its kind known. An almost black variety was termed *Eisenporzellan* ("iron porcelain"), and a black glaze was devised by Böttger to cover specimens of defective colour. Decoration is usually effected by means of applied reliefs, although the black-glazed specimens are sometimes decorated with lacquer colours, probably by Martin Schnell (d. c. 1740), as well as with gold and silver. Silvering was not uncommon, and was also practised in other German centres during the early part of the 18th century on both stoneware and porcelain. It has nearly always oxidized to black, and grave risks attend any attempt to revive the original colour. Böttger obviously intended, at first, to imitate the wares of I-hsing (see *China: Ming Dynasty*, above), and a few surviving examples are direct casts from Chinese originals, but the court goldsmith, J. J. Irmingier (d. c. 1722), soon influenced the style in the direction of contemporary metalwork.

A particular feature of Meissen stoneware is the decoration done by lapidaries. Many specimens were engraved with coats of arms, and grinding into facets (the *Muscheln* pattern) was also practised. The same methods were used to give a plain surface a high polish. Engraved decoration was sometimes executed on stoneware at a later date, usually to increase the value, and considerable knowledge is sometimes needed to detect the fraud.

Metal mounts, common on Rhenish stoneware, also were sometimes accompanied by precious and semiprecious stones set in the stoneware body.

Because of the vogue for porcelain stoneware manufacture declined in the 18th century and it was finally abandoned about 1750. It was copied early in the 18th century at Plaue an der Havel, and a brown-glazed stoneware with decoration in gold and silver from Bayreuth was obviously made with the same end in view. Modern reproductions have also been attempted.

Tin-Enameled Ware.—Faïence factories were so numerous that it is only possible to mention the most important. Perhaps the earliest tin-glazed wares other than stove tiles are the amusing jugs in the form of owls which came from Brixen (Bressanone) in the Tirol. Their detachable heads formed a cup and their shape and style no doubt inspired the later owl and bear jugs made in England during the 18th century which had similarly versatile heads. These *Eulenkrüge* were, at first, used as prizes in archery contests, and were sometimes repeated in Rhenish stoneware. The first manufacture of faïence on a considerable scale, however, took place at Nürnberg, and some dishes in the Italian style still survive. The earliest specimen which can reasonably be attributed to it is dated 1526, and it is possible that Nürnberg actually preceded Brixen in point of time.

Much more is known of the productions of Kreussen. The factory started at the beginning of the 17th century, when it was

under the direction of Lorenz Speckner, and is chiefly of interest for its blue-and-white faience jugs. The outline of flowers painted in blue is almost cross-sectional in style and terminates in a small spiral—hence the name "spiral family."

A factory at Hanau, near Frankfurt am Main, was started in 1661 and remained in operation until about 1806. Many of the early wares were decorated with Chinese motifs. A type of jug with a narrow neck, the *Engelskrug*, was made in Hanau. (Those with a globular body were sometimes copied in China and Japan in blue painted porcelain.) Others have a spirally fluted body and a twisted handle. Pewter or, less often, silver covers were common. The painting includes coats of arms, landscapes, and biblical subjects. Groups of dots amid strewn flowers (*Streublumen*) are characteristic and help to identify some of the faience. Realistically painted German flowers (*deutsche Blumen*) appear shortly before mid-18th century. Most painting is in blue, manganese, and the other high-temperature faience colours. Enamels do not seem to have been used.

A factory in Frankfurt am Main itself was founded in 1666. Imitations of Chinese motifs were very popular, as well as biblical subjects. The blue is brilliant, and the surface usually suggests the use of an overglaze. *Engelskrüge* were commonly made and are sometimes difficult to distinguish from those of Hanau. This centre closed about 1740. At Nürnberg a factory was established about 1712, continuing until about 1840. Most of the subjects used at Frankfurt and Hanau were repeated, as were designs based on the Rococo engravings of J. E. Nilson (1721–88), which were also popular at many of the porcelain factories. The Rococo style, which spread from France to Germany about the second quarter of the 18th century, is reflected both in the forms and the decoration.

The wares of Bayreuth are particularly interesting. Early products were painted with a misty blue, but enamel colours were speedily adopted. *Laub-und-Bandelwerk* was a much used type of motif and excellent work was done by A. F. von Löwenfinck, whose work on porcelain is well known, and J. P. Dannhofer. Perhaps the finest 18th-century faience was made by the factory at Höchst, near Mainz, which also manufactured porcelain. Decoration was usually in enamel colours, and landscapes, figure subjects, *deutsche Blumen*, and *chinoiserie* are of a much higher quality than elsewhere. Faience thus decorated was termed *Fayence-Porcellaine* during the 18th century.

An important aspect of both faience and porcelain decoration in Germany is the work of the *Hausmaler* ("home painters"). These men bought undecorated faience and porcelain from the factories and painted it at home, firing the decoration in small muffle kilns. For this reason, their work was done in enamel

pigments over the glaze. At first they mostly used the *Schwarzlot* technique—decoration in a black, linear style which was nearly always based on line engravings. Faience thus decorated dates from about 1660 and is the work of Johann Schaper (d. 1670) who had been a Nürnberg glass painter, J. L. Faber, and others. Polychrome enamel decoration was developed by another glass painter, Abraham Helmhack (1654–1724), who mastered the technique as early as 1690, many years before it was adopted by the factories. Undoubtedly in Europe the use of enamel colours on faience and porcelain was derived from glass painting. Another illustration of this borrowed technique is the use of enamel colours on Kreussen stoneware mentioned above.

Toward the end of the 18th century a number of German factories, including some already making faience, made lead-glazed earthenware in imitation of Wedgwood, while a factory at Königsberg (now Kaliningrad) imitated Wedgwood's black basalt body.

6. The Netherlands.—Most Dutch pottery is covered with a tin-enamel glaze. Of the medieval lead-glazed wares found in the Netherlands, most are imports from Germany, although there are a few instances of manufacture in the territory itself. During the 17th century red stoneware was made by Arij de Milde of Delft and others in imitation of the wares of I-hsing (see *China: Ming Dynasty*, above). Creamware was manufactured at several places at the end of the 18th century. Enamel decoration was added to porcelain imported from China, Japan, and, occasionally, from Meissen. Salt-glazed wares from Staffordshire, as well as a certain amount of English creamware, were decorated in the same way. Much ware sparsely decorated in blue was also overpainted with enamels, a practice known as "clobbering."

Italian potters had settled in Antwerp by 1525, and surviving examples of tin-enameled ware from this period are in the Italian style. Manufacture was concentrated to a great extent in Delft soon after the beginning of the 17th century. By about 1650 the large brewing industry began to decline, and the old buildings were taken over by potters who retained such names as "The Three Golden Ash-Barrels," "The Four Roman Heroes," and "The Double Jug" for their potteries. The craftworkers of the town were organized into the Guild of St. Luke which exercised a considerable amount of control over apprenticeships and the like and established a school of design.

In the 17th century the Dutch East India Company, chartered in 1602, imported Chinese and Japanese wares in great quantities, and the taste for Eastern decoration rapidly ousted Italian fashions. For the greater part of the 17th century decoration was in blue and Chinese porcelain was closely imitated. In wares of the best quality this imitation is so exact that, without a fairly close inspection, it is possible to mistake them for the originals. Biblical scenes were still extremely common, and landscapes and seascapes are often well painted. These and the many genre scenes are in the same styles as the paintings of the period. Tile-work was frequently undertaken and many individual tiles have survived although the large panels made up of many tiles are very rarely complete. Blue painting was followed by the use

of the usual faience colours, the outline (known as *trek*) being first drawn with blue or manganese and then filled in. Before firing the object was covered with the additional lead glaze known as *kwaart*, which made the surface more brilliant. Red was a difficult colour; often when it was to be used an unpainted space was left during the first firing and it was applied afterward and fired at a lower temperature. Gilding is found on the finer specimens and required a further firing. Enamel colours were introduced by Zacharias Dextra about 1720, and the *famille rose* patterns

BY COURTESY OF VICTORIA AND ALBERT MUSEUM; PHOTOGRAPH, WILFRID WALTER

DELFT TILE DECORATED WITH A LANDSCAPE; ABOUT 1700. SIZE: 10 IN. SQ. IN THE VICTORIA AND ALBERT MUSEUM

were frequently imitated. Among the rarer and more showy examples of Delft may be numbered the *delft dorée* on which gilding is lavish, and the *delft noir* which has a black ground, suggested by Chinese lacquer work, in conjunction with polychrome decoration. Work of this kind is often attributed to Adriaen Pijnacker.

Marks on Dutch delft are extremely unreliable for many later copies were given the earlier marks of important potteries, especially during the 19th century.

7. Britain.—Medieval Pottery.—The medieval pottery of England was affected little by outside influences. Poor communications prevented the industry from concentrating in any one place, and most wares, therefore, are made of local clay by local craftsmen. The potters worked either alone or in extremely small groups and their tools were few and simple. There are almost no records of consequence before the 16th century, and it is therefore impossible to find sufficient information on which to base a systematic classification of the wares in question. The clay used for the body contains iron, and it ranges from buff to red, or, when it was fired in a reducing atmosphere, from gray to almost black. The clay was commonly mixed with sand, and, as in much Japanese pottery, little effort was made to disguise the method by which the vessel was formed, pronounced ridges frequently being visible. Both relief and inlaid decoration is found, especially on tiles, and brushed slip was also used to add simple patterns.

Unglazed ware was common, especially in the early period, but a soft lead glaze came into more general use later, the knowledge probably being derived from France. The glaze varied between yellow and brown according to the iron content of the clay, although a group having a particularly rich brown glaze was made by first washing the pot with slip containing manganese. The use of copper oxide to give a rich green of variable colour dates from the 13th century. The green, buff, and brown glazes were used in conjunction. "Cistercian" wares, made in the monasteries before their dissolution in 1536–39, are more precisely finished. They have a dark brown glaze over a stoneware body and are sometimes decorated with white slip, or incised. By far the greater number of surviving specimens are jugs and vessels for storing liquids, and since they have almost always been excavated, a reasonably perfect specimen is a rarity.

Tin-Enameled Ware.—Lead-glazed wares tended to die out after tin glaze reached England via the Netherlands about 1550. At first it was called "gallyware," but the name was later changed to "delftware" with the rise of the Dutch manufacturing centre at Delft. Its popularity was due to the fact that it could be painted in bright colours. The earliest surviving examples are the Malling jugs, so called because an early specimen of the kind was preserved in the church at West Malling, in Kent. These were almost certainly made in London, and usually have silver or pewter mounts. The colour varies from turquoise to black, while a variety with a blue ground flecked with orange was probably suggested by the "tigerware" from the Rhineland. Similar mounts, often of English manufacture, are to be seen on Rhenish jugs imported into England, and occasionally on Turkish jugs of about the same period.

By 1628 a flourishing factory had been established at Southwark, in London, and dated specimens are known from this time onward. Many are decorated in blue with birds amid floral and foliate motifs based on some blue-and-white porcelain of the reign of Wan Li (1572–1690). Inscriptions with the name of the owner are relatively common, as they are on English wares of all kinds. Almost contemporary are some large dishes painted in polychrome high-temperature colours. The earliest, which is in the London Museum, is dated 1600 and bears the following couplet:

The rose is red and leaves are grene
God save Elizabeth our Queene.

The dish has a border of blue dashes and is a forerunner of the so-called "blue dash" chargers which were popular later in the century and were decorated with biblical scenes (that of Adam and Eve being a special favourite), crude portraits of the kings of England, ships, armorial bearings, and the like. The influence of Italian *maiolica* is also to be seen.

Many wine bottles are extant, often with the name of the wine ("Sack," "Claret," etc.) painted in blue, with the date. Others are more elaborately decorated and a few are in polychrome.

Toward the end of the 17th century painting becomes more colourful and service ware more frequent (although tea ware is now scarce). Blue and white was still made in large quantities but the high-temperature palette is much more in evidence and the influence of Dutch potters is often obvious.

Chinese influence, which had been particularly strong in the early part of the 18th century tended to persist, particularly at Bristol. Rococo decorations were used to a limited extent. Later some not very successful attempts were made to utilize the Neo-classical style. Overglaze enamels appear after the middle of the century but were probably only used at Liverpool. Also from Liverpool are many specimens, including tiles, decorated with transfer printing by John Sadler (c. 1720–89) and Guy Green (retired 1799). They claimed to have evolved this technique independently of John Brooks of London who is generally credited with discovering it about 1753.

The main centres of production were in London (Southwark and Lambeth), Bristol, and Liverpool, although there were smaller potteries elsewhere. Wincanton in Somerset made frequent use of manganese. The tin glaze fell into disuse about the turn of the 18th century, its place having been taken by Wedgwood's creamware. In the mid-20th century manufacture has been successfully revived at Rye, in Sussex.

Slipware.—Wares decorated with dotted and trailed slip were made at Wrotham, in Kent, and in London during the first half of the 17th century. Wrotham is noted principally for drinking mugs with two or more handles, known as *peasant wares*, and London for dishes with pious exhortations obviously inspired by the Puritans, for example "Faste and Pray." In the same century manufacture was started in Staffordshire and many surviving examples were signed by the potter in slip. The work of Thomas Toft is particularly valued although dishes signed by other potters, including another member of the Toft family called Ralph, are known. The best work of this kind was done before the end of the 17th century and although it may fairly be described as "peasant ware" many of the earlier specimens are vigorously decorated and amusing. Manufacture continued until the end of the 18th century.

17th-Century Stoneware.—The popularity of Rhineland stonewares in England, as well as that of the newly imported Chinese teapots from I-hsing kilns led to attempts to imitate both forms of this medium. Patents for making copies of Rhineland stoneware were granted as early as 1626, but the first known to have been exercised was awarded to John Dwight (1640–1703) at Fulham in 1671, both for porcelain and for the so-called "Cologne" ware. As well as "German" stoneware he made a brown-glazed stoneware decorated with stamped ornament which was continued at Fulham after his death and has been extensively reproduced since. He probably never made any porcelain but he mentions "red china," which can only refer to imitations of the I-hsing stoneware. His misuse of the term "china" is probably accounted for by the fact that a few specimens of thinly-potted stoneware are slightly translucent. Some remarkably fine figures in drab-coloured stoneware have survived, reputedly modeled by the sculptor and wood-carver Grinling Gibbons.

The brothers John Philip and David Elers, of German origin, made "brownware" and "red china" at a factory not far from that of Dwight in Fulham. They later moved to Bradwell Wood in Staffordshire where they found a vein of suitable clay and continued to make red stoneware. Their monopoly in Staffordshire

BY COURTESY OF VICTORIA AND ALBERT MUSEUM
ENGLISH SLIPWARE DISH BY THOMAS TOFT; ABOUT 1685. DIAMETER: 17½ IN. IN THE VICTORIA AND ALBERT MUSEUM

was short-lived, and it is difficult to separate their work from that of Dwight, on the one hand, and that of their Staffordshire imitators, on the other. Most wares are decorated with stamped reliefs, the Chinese prunus blossom being comparatively common. The tendency to utilize patterns from silverwork which is apparent on some examples may be connected with the fact that the Elers had been silversmiths. The Elers' migration to Staffordshire perhaps can be regarded as the starting point for the large modern industry which has grown up in that area. Certainly from this time onward Staffordshire wares tend to lose their "peasant" character and to approach a factory-made precision which was to be general by the end of the 18th century.

The earlier red- and brown-glazed stonewares were replaced about 1690 by a salt-glazed stoneware which was regarded as an acceptable substitute for porcelain. This varies in colour from drab to off-white, the glaze on later specimens often having a richer, more glassy appearance due to the addition of red lead. One of the earliest varieties is decorated with stamped reliefs on pads of clay which were applied to the surface.

18th-Century Developments.—The "scratched blue" class of white stoneware dates from about 1730, and is decorated with incised (or scratched) patterns usually touched with blue. Decoration is floral, and inscriptions and dates are fairly frequent. Its manufacture survived until about 1775.

From the 1730s molded patterns in relief were popular, the clay being pressed into molds of metal, wood, or fired clay. The introduction of plaster of Paris molds (see *Introduction: Methods of Fashioning Ceramics*, above) devised by Ralph Daniel of Cobridge about 1745 gave much greater scope and led to the development of intricate shapes in the finer varieties of white stoneware. The patterns greatly increased in sharpness and complexity; silver patterns especially were copied and elaborate piercing is to be seen.

As mentioned above, transfer printing was first used about 1755. The earliest enameled painting belongs to the same period—previously white wares had been sent to Holland for decoration. The man who first mastered the technique was William Duesbury. He was established as a decorator in London by 1751 and, while he concentrated on painting porcelain (see further *European Porcelain: Britain*, below), it appears from his surviving account books that he also enameled stoneware from Staffordshire. Some extant brilliantly enameled figures are probably from his studio, in some cases copies of contemporary models from Meissen. A little earlier than Duesbury's enameled figures are the "Pew" groups which consist of two or three figures seated on a high-backed settle or pew, modeled in a primitive and amusing fashion.

Enameling in Staffordshire is thought to have been introduced by two Dutchmen who were at Hot Lane, Cobridge, about 1755: however, little is known of them and the name of Willem Horologius, sometimes associated with them, is apocryphal. A rich blue ground is often called Littler's blue after William Littler, the man who is thought to have invented it. He was one of the partners at Longton Hall where a porcelain factory, which also made salt-glazed stoneware, was established in 1751 and made much use of the blue. The attribution has been confirmed from fragments and "wasters" discovered on the site of the old factory by Bernard Watney in 1955.

John Astbury is particularly associated with a type of brown-glazed ware decorated with stamped pads of white clay. A surviving example depicting the victory of Admiral Vernon at Porto Bello is dated 1739 (Victoria and Albert Museum, London). Some of the earliest Staffordshire figures in brown and white clay covered with a lead glaze have been attributed to Astbury. It is probable that his son Thomas experimented with the lead-glazed earthenware which was later to be known as creamware and, improved by Wedgwood, eventually renamed Queen's ware. It was developed from the earlier white stoneware body and covered with a lead glaze.

Thomas Whieldon (1719–95) of Fenton Low, Staffordshire, manufactured "agateware"—that is, ware made by combining differently coloured clays or by combing together different colours of slip. In the former method the clays were usually laid in slabs,

one on the other, and beaten out to form a homogeneous mass in which the colours were inextricably mingled. Agatewares seem to have been made between 1725 and 1750, the earlier specimens being salt-glazed while the later ones were covered with a colourless lead glaze. Whieldon is most famous for his use of coloured glazes which were mingled to give a clouded or tortoiseshell effect and were used on an earthenware body, sometimes over molded decoration. A few naively modeled figures with this type of glaze are attributed to him. From 1754 to 1759 he was in partnership with Josiah Wedgwood, who developed the fine green and yellow glazes to decorate molded wares in the form of pineapples, cauliflowers, and the like. A rich black glaze, sometimes decorated with gilding, was made by Whieldon and at Jackfield, in Shropshire.

Coloured glazes were also used by Ralph Wood (1715–72) of Burslem, Staffordshire, for decorating an excellently modeled

series of figures in a creamware body, the finest being perhaps a mounted Hudibras in the Victoria and Albert Museum. Many of these figures are attributed to the modeler Jean Voyez, who was much influenced by the work of P. L. Cyfflé at Lunéville (see *France*, above). Enoch Wood, another member of the family, started work on his own account in 1783 as Enoch Wood & Co. He made most of the wares current in Staffordshire at the time, as well as some excellent figures decorated with overglaze colours.

series of figures in a creamware body, the most famous of all the Staffordshire potters, is chiefly celebrated for his fine jasper and black basaltes stonewares but his creamware was undoubtedly the more influential. It was well finished and clean in appearance with simple decoration in good taste, often in the popular Neoclassical style. His wares appealed particularly to the rising bourgeois class, both in England and abroad, and porcelain and faience factories suffered severely from competition with him. Surviving factories switched to the manufacture of creamware (*faience fine* or *faience anglaise*) and the use of tin enamel died out. Even Sèvres and Meissen found themselves in difficulties financially. Wedgwood's jasper wares were imitated in biscuit porcelain at Sèvres, and Meissen produced a glazed version which they called *Wedgwood-arbeit*.

Wedgwood secured the patronage of Queen Charlotte for his creamware in 1765, and renamed it Queen's ware. Much of it was transfer printed by Sadler and Green at Liverpool. Evidence of its popularity and importance is provided by the enormous service of 952 pieces made for Catherine the Great's palace of La Grenouillère in St. Petersburg.

The basaltes ware, also called black porcelain or Egyptian ware, was a type of stoneware introduced about 1768. Like the jasper which followed, it was used almost entirely for ornamental work; vases, ewers, candlesticks, plaques, medallions, and tea and coffee ware were made. Some of it was painted in what Wedgwood called "encaustic" enamel, but most of the decoration was either molded and applied, or incised by turning on a lathe.

Jasper was introduced about 1775. It is a fine-grained white unglazed stoneware, which is slightly translucent when thinly potted. Undoubtedly it was inspired by the biscuit porcelain of Sèvres. Its name derives from the fact that it resembles the natural stone in hardness. At first the body was stained blue with applied decoration in white. Other colours followed speedily. Like basaltes, jasper was used mainly for ornamental wares, but perhaps the most interesting products are the portrait medallions of contemporary notabilities. Vases do not appear to have been made until after 1780, and in 1790 Wedgwood produced the first

copies of the Portland vase, a magnificent Roman vase of dark blue glass decorated with white figures, at that time owned by the duke of Portland but now in the British Museum (see GLASS). The vase was extensively copied in later years, particularly in Victorian times. Toward the end of the 18th century Sèvres began to copy Wedgwood's reliefs on vases and plaques for furniture decoration. Less influential were the red stoneware (*rosso antico*), which sometimes had an enameled decoration of classical subjects, and caneware, a buff stoneware, old specimens of which are fairly common.

Wedgwood's productions were extensively copied by William Turner, William Adams, Enoch Wood, and others, and forgeries of one kind or another are numerous.

Lustre Pigments, introduced into England toward the end of the 18th century, are used in a manner quite different from the earlier styles of other countries. To simulate silverwork wares were completely covered with platinum lustre which remains unchanged in colour after firing (silver itself yields a pale straw colour), the amount of metal used, of course, being extremely small. Such wares were known as "poor man's silver." Wares were also painted or stenciled with lustre patterns. The most valuable type commercially are the "resist" lustres which have a lustred background and the pattern reserved in white. They were made by painting or stenciling the pattern on the glaze with shellac which "resisted" the subsequent application of the metallic pigment. Silver lustre was rarely used but gold lustre, which gives variable colours from pink to purple, was fairly common. Copper, whose colour remains more or less unchanged in its lustre form, was used throughout the 19th century for common wares.

Scotland.—There were three pottery-making centres of minor importance in Scotland. A factory for the manufacture of tin enamel was established in Glasgow in 1748, but only one specimen can now be identified with certainty. In the 19th century the principal factory belonged to J. & M. P. Bell and was noted for blue painted earthenware and Parian statuettes of good quality. Pottery was made at Prestonpans in the 17th century, and in the 18th century figures, punch bowls, and similar items were produced by Watson's factory. Ornamental pottery of all kinds was produced at Porto Bello from about 1786 onward. In 1810 a Staffordshire potter became a partner, after which the factory's work begins to resemble that of Staffordshire; its wares were copied by a factory at Tunstall, Staffordshire, in the 1820s.

8. Scandinavia.—The faience industry spread to Scandinavia mainly because of migratory workmen from Germany. There were a number of factories located in Denmark, Norway, and Sweden during the 18th century which made faience, and creamware in the English manner. Bowls in the shape of a mitre were made for a kind of punch called "bishop," and these are a distinctive Scandinavian production. The most important factories are those of Rörstrand and Marieberg (Koja) in Sweden. A Rörstrand workman later at Marieberg, Anders Stenman, is reputed to have discovered the art of transfer printing independently, and the manager of the Marieberg factory, Pierre Berthevin, later went to Frankenthal, where he experimented with this form of decoration. Berthevin was, at one time, at the French factory at Mennecy, and the influence of Mennecy can be seen in the wares of Marieberg.

WEDGWOOD JASPER WARE

Blue and white jasper ware vase by Josiah Wedgwood; Staffordshire, England, about 1785. Height: 18 in. In the Victoria and Albert Museum

A typical Rococo concept to come from Marieberg is the "terrace" vase. This has a vase standing at the top of a winding flight of steps, often with a rabbit or some other animal at the bottom.

A factory at Kiel, Ger., under the direction of J. S. F. Tännich, formerly of Strasbourg, did excellent work. There were two factories operating in Copenhagen, and one at Herrebøe, in Norway. Ulfsunda, in Sweden, made many close copies of Wedgwood's basalt ware and the *rosso antico*.

L. EUROPEAN PORCELAIN TO THE END OF THE 18TH CENTURY

1. General Outline.—*Soft Porcelain.*—The manufacture of soft porcelain was essayed in Italy under the patronage of Francesco de' Medici. Similar attempts were made elsewhere in Italy about the same time, and manufacture is supposed to have been continued at Pisa, and at Candiana, near Padua. However, no specimens from these factories are known, and the first production of soft porcelain on a considerable scale did not take place until toward the end of the 17th century in France.

Hard Porcelain.—In Saxony about 1675 Ehrenfried Walter von Tschirnhaus started experiments to make porcelain from clay mixed with fusible rock. Almost certainly he had made hard porcelain by the end of the century but manufacture did not become a practical commercial proposition until the year of his death in 1708. Experiments were continued by his assistant, an alchemist named Johann Friedrich Böttger, who is sometimes credited with von Tschirnhaus' discovery. The factory was established at Meissen about 1710, and the first porcelain sales of any consequence took place at the Leipzig Fair in 1713. Early production was divided between the red stoneware, which had been discovered in the course of the experiments (see *European Pottery: Germany*, above) and hard porcelain, the latter becoming the sole manufacture after about 1730.

Styles.—Style is of great assistance in dating 18th-century European porcelain. The early porcelain, when it is not copied from Chinese or Japanese wares, is Baroque in form and decoration. Some of the figure modeling at Meissen shows a typical Baroque exaggeration of gesture. The *lambrequins* and the *Laub- und Bandelwerk* which appear on both the faience and porcelain of the time are characteristic forms of Baroque ornament, as are the designs of Jean Bérain.

The early part of the 18th century saw the first essays in the Rococo style which developed from Baroque. Its name is derived from the French *rocaille*, or "rockwork," probably because the earliest motifs were based on wave, rock, and shell patterns. The first important Rococo work in porcelain—the Swan service, made at Meissen for the director, the Graf Heinrich von Brühl—was started in 1737, the decorative motifs being swans, nereids, tritons, etc. Later Rococo ornament is characterized by scrollwork whose asymmetry contrasts with the symmetrical Baroque use of similar motifs.

In Rococo pieces form is often subsidiary to ornament. Porcelain figures appear on bases profusely ornamented with scrollwork and occasionally, as for example on those from Frankenthal, the scrollwork is carried upward, dwarfing the figures themselves. The backs of figures and groups tend to be sketchily finished, and since many such figures were derived from engravings, it seems that the modeler had no clear idea of what ought to be on the other side.

Rococo had run its course by the middle of the 18th century and was followed by a revival of classical motifs as a result of the excavations at Pompeii and Herculaneum in the mid-18th century. The resulting style has come to be known as "Neoclassical" and is often referred to in England as the Adam style because the brothers Adam were its principal exponents. In France the earliest, or Louis Seize (Louis XVI), phase retained some of the elements of the Rococo. Later the style became increasingly severe, especially during the French Revolution. In the early part of the 19th century, under Napoleon, it was transformed into the Empire style which was little more than a pompous and ostentatious copy of imperial Roman art.

In Germany Neoclassicism took a slightly different course since it became mingled with the Romantic movement. Its sentimental

vein is well illustrated by the figures and groups of the Meissen modeler Michel Victor Acier, and in England by the work of the painter Angelica Kauffmann and others. In the 19th century a revival of the Rococo style incorporated the worst elements of both.

Both the Baroque and Rococo are satisfactory styles for porcelain. Neoclassicism, however, was suited neither to this medium nor to faience. It found its ideal material in the cream-ware of Wedgwood, the most important exponent of Neoclassicism in the field of ceramics.

Many imitations were made of Chinese wares, but perhaps the most important Far Eastern influence during the first half of the 18th century was that of Arita (see *Japan*, above). The designs of the Kakiemon family were copied at almost all the porcelain factories, in particular at Meissen and at Chantilly.

2. France.—In the second half of the 17th century much interest was taken in *faïence* and porcelain although the technique of making soft-paste porcelain (*pâte tendre*) had yet to be mastered, and the secret of hard-paste, or "true," porcelain manufacture was not discovered till the 18th century. In 1664 a privilege had been granted to Claude and François Révérend for the manufacture of porcelain. A similar privilege was granted to the faience maker Louis Poterat of Rouen in 1673, yet from contemporary records it seems that little porcelain was manufactured. Some specimens decorated in the manner of Rouen faience, or with the armorial bearings of local families, have been attributed to Poterat but it is possible that some of these, as well as some rare examples hitherto tentatively attributed to Révérend, may have been made by M. Morin who had moved to Saint-Cloud. In 1698 Martin Lister visited Saint-Cloud and records that Morin had been experimenting with soft porcelain for 20 years, but had only achieved success 3 years before.

Another factory at Saint-Cloud, which was probably a separate establishment, was founded by Pierre Chicaneau in the 1670s and was afterward directed by his son's widow and her second husband, Henri Charles Trou. Its wares were yellowish in tone, and heavily potted. Much use was made of molded decoration, which included sprigs of prunus blossom copied from the *blanc de chine* of Te-hua. Particularly common was a molded pattern of overlapping scales. Most examples are small but there are some large *jardinières* which are extremely handsome. The early painted wares were decorated in underglaze blue with typically Baroque patterns, including the *lambrequins* introduced at Rouen. Motifs derived from the designs of Jean Bérain are also to be seen. Polychrome specimens, some of which were decorated in the style of Kakiemon, date from about 1730.

A small quantity of porcelain which is sometimes difficult to separate from that of Saint-Cloud was made at Lille, and an offshoot of the former factory at the Rue de la Ville l'Évêque in Paris also made similar wares. Saint-Cloud itself finally closed about 1768.

At Chantilly the first porcelain was decorated almost entirely in the Kakiemon style, and the body was invariably covered with a tin-enamel glaze—a fact which makes it easy to recognize. The Japanese period ended about 1740. For some years thereafter Meissen styles were copied, in particular the *deutsche Blumen*. In 1753 an edict in support of the newly established factory at Vincennes forbade all other factories to manufacture porcelain or to decorate faience in polychrome; much Chantilly porcelain of the later period is creamy white decorated only with slight flower sprigs in blue underglaze. A transparent glaze was introduced in 1751. The presence at this factory of the erstwhile Meissen painter A. F. von Löwenfinck has been noted.

A factory at the Rue de Charonne in Paris was started by François Barbin in 1735, and removed to Mennecey in 1748 where it came under the protection of Louis François de Neufville, duc de Villeroy. The early productions were in the manner of Saint-Cloud and the prunus sprig motif is found. *Lambrequins* painted in underglaze blue as at Rouen and Saint-Cloud were also used. Later, some excellent flower painting was done and a few imitations of the early work of Sèvres have also been recorded. Figure modeling was excellent in quality. Small porcelain boxes from

GROUP OF CHILDREN, PORCELAIN FIGURINE FROM MENNECEY, FRANCE; ABOUT 1760. HEIGHT: 6½ IN. IN THE VICTORIA AND ALBERT MUSEUM

Mennecey, often in the form of animals, are now much sought. The work of a small factory at Crépy-en-Valois is similar, and some confusion has occurred. Mennecey was removed to Bourgl-la-Reine in 1773, where it came under the protection of the comte d'Eu.

The most important of the French factories was established at Vincennes about 1738 and removed to a new building at Sèvres in 1756. The moving spirit behind the original factory was Orry de Fulvy, brother of the minister of finance, who was at first assisted by two workmen from Chantilly, Gilles and Robert Dubois. They achieved no success until 1745 when porcelain

was at last made with the aid of François Gravant, also from Chantilly. Louis XV was a large shareholder in the original company and the factory eventually passed to the crown in 1759. It became state property in 1793, and has so remained to the present day.

The early work at Vincennes consisted of porcelain vessels decorated with naturalistic flowers and often elaborately mounted in gilt bronze by the court goldsmith, Claude Thomas Duplessis, and others. Meissen was also copied for a short period, but the factory soon evolved its own style which remained partly dependent on the use of gilt-bronze mounts of the highest quality. A few glazed and painted figures were made. These gave place to figures of biscuit porcelain. Figures in this material were first made in 1751, and in 1757 the sculptor Etienne Maurice Falconet was appointed to take charge of modeling, a position he retained until 1766. Designs by François Boucher were frequently used by Falconet and others, and Boucher's influence is particularly strong during the lifetime of Mme de Pompadour who took much interest in the factory. Later, some excellent work in this medium was done by the sculptors Augustin Pajou and Louis Simon Boizot.

Both at Vincennes and Sèvres much use was made of coloured grounds in conjunction with white panels, which were used for decorative painting of the highest quality. These panels were surrounded by rich and elaborate raised gilding which was engraved and chased. The most usual ground colours were *gros bleu* (a dark underglaze blue introduced in 1749) and the brighter *bleu*

de Roi (an enamel blue which followed in 1756). Also used were turquoise blue (1752), yellow (1753), green (1756), and the *rose Pompadour* (1757) probably invented by the painter Xhrouet and discontinued on the death of the marquise in 1764. This last colour is often misnamed *rose du Barry* in England. Many examples bear a device by which the painter may be identified as well as a factory mark.

The porcelain of Sèvres was made to harmonize with the exotic and luxurious style of interior decoration which characterized French court circles. The soft-paste body was of superb quality, and the extremely fusible glaze partly remelted in the enameling kiln causing the colours to sink into it in a way which is hardly ever seen elsewhere. Forgeries, usually in hard-paste porcelain, are particularly numerous and the mark of the factory has been much abused. White porcelain, usually with slight defects, was sold by the factory on several occasions before the end of the 18th century and decorated by outside enamelers in its own styles.

The factory prosecuted the search for the ingredients of hard porcelain with vigour, and these were found after a prolonged search at Saint-Yrieix-la-Perche, near Limoges, in 1769. The new body was first manufactured soon after 1770, although for some years it was only used for biscuit figures. Later, it was employed for services and vases decorated in a severely classical style. The director, Alexandre Brongniart, who was appointed in 1800, discontinued the manufacture of soft porcelain and sold off the stocks remaining in white.

A large number of smaller factories making hard porcelain sprang up, chiefly in and around Paris, in the second half of the 18th century. Some were patronized by members of the royal family, including Marie Antoinette. A number of provincial factories were also engaged in the same manufacture. Principally deserving of mention is that of Paul Antoine Hannong in Strasbourg, where porcelain of good quality was first made in 1751. The factory was removed to Frankenthal in the Palatinate in 1753 in consequence of the royal edict on behalf of Vincennes.

3. Germany and Austria.—The factory at Meissen was under the patronage of Augustus the Strong. Its earliest porcelain is smoky in tone but some improvements were made in 1715, and others in the following decade. Many early specimens were painted with a limited range of enamel colours of good quality, including a pale violet lustre derived from gold which remained in use until about 1730. In 1720 a painter from Vienna, Johann Gregor Höroldt, was appointed chief painter (*Obermaler*) to the factory, and he was responsible for introducing a new and much more brilliant palette, as well as some ground colours (*Fond-Porzellan*). The earliest ground colour to be noted is a coffee brown termed *Kapuzinerbraun* which was invented by the kilnmaster, Samuel Stölzel. Difficulty was experienced in using blue underglaze, and little work of the kind was done. Enamel painting, on the other hand, was of fine quality and includes topographical subjects, figure subjects which were based either on the harlequins, pierrots, and other characters of the Italian comedy or on the style of Watteau and his followers, and flowers in the Oriental style, mistakenly called *indianische Blumen* as well as native flowers taken from books of botanical illustrations (*deutsche Blumen*). A series of harbour scenes from engravings of Italian ports were mostly executed by C. F. Herold (cousin to the *Obermaler*) and J. G. Heintze. Perhaps the most important early wares are the *chinoiseries*, European delineations of the Chinese scene with a strong element of fantasy. They appear in great variety. The first work of the kind, much of it painted by the *Hausmaler*, Bartholomäus Seuter, is in gold silhouette. This was followed by a type in which the figures are painted in three-quarter length. *Indianische Blumen* motifs were used and Arita decorations, particularly those of Kakiemon were closely copied.

Little figure modeling was done until about 1727 when Johann Gottlob Kirchner was appointed *Modellmeister* and asked to make some colossal figures of animals for the Japanische Palais. The medium was unsuited to work of this kind, and most of the surviving examples are spectacular and magnificent failures. Another sculptor, Johann Joachim Kändler (*q.v.*), was employed in 1731 to assist Kirchner but soon replaced him. After the death of

Augustus the Strong in 1733 the large-scale modeling was practically discontinued and Kändler turned his attention to small figures suitable for the dining table.

Helped by Johann Friedrich Eberlein, Friedrich Elias Meyer, Peter Reinicke, and others, Kändler soon made the figures of Meissen fashionable throughout Europe and they were extensively copied elsewhere, particularly in England. The Rococo style appears in Saxony after 1737 when Kändler started to make the Swan service—perhaps the best known of all porcelain services—for Graf Heinrich von Brühl. Rococo speedily became fashionable.

Meissen was the most influential European factory until the beginning of the Seven Years' War in 1756 when it was taken by the Prussians. From then until 1763 it was operated by nominees of Frederick the Great, who virtually looted the factory. By the end of the war leadership had passed to Sèvres, and the work of Meissen in the Academic period (1763–74), and under the directorship of Count Camillo Marcolini (1774–1814), is much less important than formerly. The transitional Louis Seize style of the former period is typified by the figure modeling of Michel Victor Acier who came to the factory to share the position of *Modellmeister* with Kändler in 1764. During the latter period the designs of Sèvres and of Wedgwood (*Wedgwoodware*) were copied and the Neoclassical style was increasingly used.

The other German factories of the period were, for the most part, established with the aid of runaway workmen from Meissen and also from Vienna, where Claudius Innocentius du Paquier had started a factory in 1719 with the aid of two men, Christoph Konrad Hunger and Samuel Stölzel, who were themselves from Meissen. Early Vienna wares are highly patterned. Much use was made of *Laub- und Bandelwerk* ("leaf and scrollwork") patterns and excellent work was done in *Schwarzlot* ("black monochrome"). The factory passed to the state in 1744, and its later work is competent without being distinguished. Under Krieger and von Sorgenthal (1784–1805) it became noted for elaborate gilding and coloured grounds, with minutely detailed painting after Angelica Kauffmann and others in reserved white medallions.

The Vienna factory provided a number of "arcanists" (men who possessed the *arcanum* or "secret" of porcelain manufacture), two of whom, Johann Benckgraff and J. J. Ringler, helped to establish the Höchst factory which began manufacture about 1752. It is principally noted for excellent figures in the Louis Seize style by Johann Peter Melchior, who left in 1779 to work at Frankenthal, and for the work of Simon Fellner.

Also in the early 1750s a factory was established in Berlin by a merchant named Wilhelm Kaspar Wegely, who received some assistance from Benckgraff. It closed in 1757 after failing to obtain a subsidy from Frederick the Great but another factory, started in 1761, was acquired by Frederick in 1763 when he re-

(Left) Group of peasants by Simon Fellner; Höchst, about 1754. Height: 8½ in. (Right) Group emblematic of sculpture, model by Wilhelm Christian Meyer, Berlin, about 1775. Height: 12¼ in. In the Victoria and Albert Museum

linquished his hold on Meissen. The painted decoration of the second factory was of high quality and made much use of *mosaik* patterns—detailed diapers painted over a coloured ground. A large service made in 1819 for presentation to the duke of Wellington and decorated with scenes from his battles is now in Apsley House, London.

Much interest now centres on the figure modeling of Franz Anton Bustelli (*q.v.*), who worked at Nymphenburg, a suburb of Munich. The factory, which was still in operation in the mid-1960s, was started about 1753 with the assistance of Ringler, and was under the direction of the Graf Sigismund von Haimhausen. Bustelli became *Modellmeister* in 1754 and retained the position until his death in 1763. His magnificent series of figures based on the Italian comedy are the most important expression of Rococo in German porcelain. Another modeler of note was D. J. Auliczek. The painted wares of the factory were also of fine quality.

Some excellent figures were made at Fürstenberg, where porcelain was first manufactured in 1753 with the aid of Benckgraff, and at Frankenthal, to which the Strasbourg factory was removed in 1753 (see *France*, above). Frankenthal employed some notable modelers; e.g., J. W. Lanz (from Strasbourg), the cousins J. F. and K. G. Lück, and Konrad Linck, the latter working in the Louis Seize style. Ludwigsburg, started in 1756, was taken over by the Duke Karl Eugen of Württemberg in 1758. The porcelain was grayish in colour, and more suitable for figure modeling than for service ware. The figures of artisans by an artist known as the *Modeller der Volkstypen* ("modeler of folktypes") are original and pleasing, and the sculptor, J. C. W. Beyer, did good work in the Louis Seize style. A factory founded at Fulda by Prince-Bishop Heinrich von Bibra did some distinguished figure modeling while smaller factories at Onolzbach (now Ansbach), Ottweiler, Cassel, Pfalz-Zweibrücken, and Kelsterbach, for the most part produced competent imitations of work from the larger factories. A number of factories in the Thüringer Wald made provincial wares which often have a good deal of charm.

Much important work was done in the early period by the *Hausmaler*—independent decorators who bought white porcelain and painted it at home. The more important are Johann Aufenwerth and Bartholomäus Seuter of Augsburg, J. F. Metsch of Bayreuth, the Bohemians Daniel and Ignaz Preussler, and Ignaz Bottengruber of Breslau. The work of the latter is particularly esteemed. Christoph Konrad Hunger, who was at Meissen and Vienna, devised a method of using raised gilding in conjunction with translucent enamels, a technique which can also be seen on some early French porcelain and on enameled copper from Alex. Fromery of Berlin. An unusual technique was devised by A. O. E. von dem Busch, canon of Hildesheim, who engraved his designs in the glaze with a diamond, subsequently filling the incisions with black pigment.

Few marks have been so consistently abused as that of the crossed swords of Meissen. During the 18th century the Thüringian factories belonging to the Greiners adopted marks which could easily be mistaken for it, and it has since been added to all kinds of unlikely specimens. Many reasonably good copies of Meissen figures have been made at Potschappel (Pottschappelitz) near Dresden and in Paris, and variations in colouring are sometimes the only serious points of difference. The Meissen factory, too, occasionally used its old molds at a later date. Crude copies of an early design were made in Dresden during the 1870s by Helena Wolfsohn, who used the royal monogram (AR for Augustus Rex) as a mark. Their tawdry nature is always apparent.

4. Britain.—A factory for porcelain manufacture, using a body similar to that of Saint-Cloud, was established in Chelsea in 1743 by Charles Gouyn and Nicolas Sprimont. The rare surviving specimens include jugs molded in the form of goats and further decorated with an applied bee, a style based on one current in silverwork some 15 years earlier. These, the so-called "Goat and Bee" jugs, are often marked with an incised triangle, which was then the mark in use. About 1750 Gouyn retired. A new body was adopted, together with the familiar mark of an anchor, which was raised on a small medallion until about 1752, painted in red until about 1756, and executed in gold thereafter. The work of

BY COURTESY OF VICTORIA AND ALBERT MU-

ENGLISH PORCELAIN FROM CHELSEA

Figure of a carpenter; period of the raised anchor mark, about 1752. Height: 7¾ in. In the Victoria and Albert Museum

the Chelsea factory was extensively influenced by Meissen until about 1756, the styles of Sèvres superseding it in the gold anchor period. Wares marked either with the raised or the red anchor are the most highly valued, and painting is excellent in quality. Some of the best were painted by the Irish miniaturist, Jeffries Hamett O'Neale, whose work is much more frequent on Worcester porcelain at a later date. The gold anchor marked wares are noted for rich gilding and some fine coloured grounds which, on occasion, rivaled those of Sèvres. The figures in the later Rococo style are generally inferior to those of the early period. Some Chelsea porcelain from 1760 onward was painted in the studio of James Giles of Clerkenwell, whose work, like O'Neale's, is much more frequent on Worcester porcelain. The factory was bought by William

Duesbury of Derby in 1770 and entered a phase known as the Chelsea-Derby period. The Neoclassical style was introduced together with the figures in the biscuit porcelain made fashionable by Sèvres. It closed finally in 1784.

A group of figures, the best-known examples of which are those portraying the "Girl in a Swing," were possibly made at Chelsea but more probably at a short-lived factory directed by Charles Gouyn and staffed by workmen who had seceded from Chelsea. They can be dated with reasonable certainty to the early 1750s. No complementary service ware has been positively identified.

A factory was established in Derby about 1750, and a class of figures characterized by a retraction of the glaze from the base—"dry-edged" figures—are attributed to it. It appears that this first enterprise petered out and that another factory in Derby was started by Duesbury in 1756. It advertised itself as "the second Dresden" and is principally noted for the excellence of its painting toward the end of the century, the artists being Zachariah Boreman, William Billingsley, and others.

The Bow factory (London) was started as early as 1744 with the aid of clay brought from Virginia by the American settler Andrew (André) Duché, who had discovered the secret of manufacture quite independently some years before. An amusing and primitive class of Bow figures was executed by an anonymous artist known as the "Muses Modeler" because the most typical figures portray the muses. Generally speaking Bow wares are unsophisticated and the factory obviously catered for prosperous tradesmen, a market ignored by Chelsea. An important technical innovation took place at Bow in 1750 when calcined bones were added to the porcelain body. This was the first major departure from the French soft-porcelain formula, which was fundamentally a mixture of clay and ground glass. Bone ash was added to soft porcelain by Chelsea about 1755, by Lowestoft (which mainly copied Bow styles) in 1758, and by Duesbury in 1770 when he purchased the Chelsea factory. About 1800 at his factory at Stoke-on-Trent, Staffordshire, Josiah Spode the second added calcined bones to the hard porcelain formula to produce the standard English bone-china body.

Longton Hall in Staffordshire was started about 1750, one of the partners being a salt-glaze potter named William Littler. The figures are naive, and much of the service ware was molded in the form of leaves. A rich blue ground (Littler's blue) was used on porcelain and salt-glazed ware alike. The factory closed in 1758.

Another variation on the original soft-porcelain body was introduced at a factory in Bristol started by Benjamin Lund about 1748. Clay was mixed with a fusible rock called steatite (hydrous

magnesium silicate), the principle being similar to that used in the manufacture of hard porcelain. This factory was transferred to Worcester in 1752, and was still in operation in the mid-20th century. In the 18th century "scale" grounds, which consisted of patterns of overlapping scales in various colours, were particularly popular. Transfers taken from engraved plates were also extensively used for decoration. Worcester was bought by Thomas Flight in 1783, and later wares show a progressive decline in taste. Small factories using a similar body were established at Liverpool, and at Caughley, in Shropshire. A second factory was established at Worcester by Robert Chamberlain in 1786 (see *19th and 20th Centuries in the West*, below).

William Cookworthy (q.v.) discovered the secret of hard porcelain independently after many years of experiment. He opened a factory at Plymouth in 1768, and this was transferred to Bristol in 1770. He made figures in the style of Bow and Longton Hall. Richard Champion acquired the patent in 1772 and manufactured tableware which is Neoclassical in style and excellent in quality. The patent was bought by a syndicate which established a factory at New Hall, Staffordshire, in 1782 and made a humbler variety wares for about 40 years.

5. Other European Countries.—Switzerland.—A factory started near Zürich in 1763 was directed by Adam Spengler, formerly a painter at Höchst. Both faience and porcelain were made, and, after 1790, creamware was also manufactured. Delicate figures, some modeled by J. V. Sonnenschein from Ludwigsburg, and good quality service ware were produced. A factory at Nyon, founded about 1780, made porcelain in the style of the Paris factories.

Belgium.—The Tournai factory which began to make porcelain in 1751 enjoyed the patronage of the empress of Austria, Maria Theresa, and during the early period exchanged several artists with the English Chelsea factory. Here, and in the associated factory at Saint-Amand-les-Eaux, the work of Sèvres was imitated on a considerable scale. Tournai porcelain sold "in white" was decorated at The Hague.

Denmark and Sweden.—After a number of attempts a factory, which used clay from the island of Bornholm, was established in Copenhagen. In 1760 it was directed by Louis Fournier, a modeler from Vincennes and Chantilly, and a type of soft porcelain was made, few examples of which survive. The manufacture of true porcelain began in 1774 with the aid of workmen from Fürstenberg, and the factory was acquired by King Christian VII of Denmark and Norway in 1779. In 1789 the factory started to make an enormous service, originally intended for Catherine the Great, each piece of which was painted with detailed picture of a Danish flower. This service, the *Flora Danica*, is now in Rosenborg castle, Copenhagen. Numerous skilfully made figures were also produced. The factory continues to produce fine porcelain. A factory at Marieberg (Koja), near Stockholm, started in 1766, and its early work was strongly influenced by that of Mennecy. Quality began to deteriorate after about 1770, and the factory closed in 1788.

Russia.—The factory of St. Petersburg was established about 1745. Later production was on a fairly large scale, and the work of Sèvres and Meissen was freely copied. Some good original work was also done, and well-modeled figures of Russian peasants were made toward the end of the century. Even better figures were made at a factory in Moscow which had been founded in 1758 by an Englishman named Francis Gardner. Another factory near the same city was started by A. Popoff in 1806. A number of small factories elsewhere in Russia were established during the 19th century.

Italy.—There are only about 50 surviving pieces of the porcelain made in Florence at the time of the Medicis, and little is known of its actual production. Giorgio Vasari, in his *Lives of the Painters*, refers to experiments in porcelain manufacture and contemporary records mention a "Levantine" assistant, who may have been a Persian with knowledge of Near Eastern experiments in mixing clay with glaze material. A formula is preserved in the Biblioteca Nazionale Centrale, in Florence, which helps to confirm this supposition. The earliest definite date for manufacture is 1581, a flask in the Sèvres Museum being so dated. Painting

BY COURTESY OF VICTORIA AND ALBERT MUSEUM
BOTTLE OF MEDICI PORCELAIN: ABOUT 1580. HEIGHT: 6½ IN. IN THE VICTORIA AND ALBERT MUSEUM

is nearly always in blue with manganese outlines; a polychrome specimen is doubtfully attributed. Most decorative motifs are derived from China, Persia, or Turkey, and the forms usually copy those of Urbino maiolica. Specimens are to be found in most important museums.

No hard porcelain was made in Italy until Francesco and Giuseppe Vezzi's factory was established in Venice in 1720 with the aid of Christoph Konrad Hunger. It made fine hard porcelain whose body has a slightly smoky colour. The style is Baroque and the palette is notable for a brownish red. Another factory, that of Geminiano Cozzi, started in 1764, was the one where most Venetian porcelain was made. Cozzi worked in the Meissen and Sèvres styles, and produced some good figures.

The factory at Doccia, near Florence, which was still in production in the mid-1960s, was founded by Marchese Carlo Ginori in 1735. Coffeepots in the Baroque style, sometimes painted with coats of arms, are characteristic of the early period. Equally fine figures were made during the 18th century. Porcelain with figure subjects in low relief was made only at Doccia although it has been repeatedly attributed to the soft porcelain factory established in the royal palace of Capodimonte by Charles III of Naples in 1743. As well as extremely well-painted service ware, Capodimonte is renowned for its figures. The factory was transferred to Buen Retiro, near Madrid, in 1759 when Charles became king of Spain. Another factory at Naples was established in 1771 by Ferdinand IV of Naples but its wares are not of very great importance.

Other factories at Le Nove (near Bassano), Vinovo (near Turin), and Treviso (near Venice) produced interesting and competent wares.

Spain and Portugal.—The early porcelain, made at Buen Retiro has been justly compared to that of Saint-Cloud. The quality of the ware was good, and some skilful figure modeling was done by Giuseppe Gricci, who had previously worked at Capodimonte. The factory closed in 1808, but manufacture was revived at La Moncloa (Florida, near Madrid) in 1817 and lasted until 1850. Porcelain was also made at the Alcorta faience factory from 1774, but production was artistically undistinguished. The same is true of the wares from the factory at Vista Alegre, near Oporto, in Portugal, which was still in production in the second half of the 20th century.

M. THE AMERICAS TO THE END OF THE 18TH CENTURY

1. Indian Pottery.—The extent to which the original inhabitants of the Americas developed in isolation from the Old World is a controversial question but one in which the researches of the ceramic historian may assist the ethnographer. The American Indians are of Asiatic descent and their route to the New World was from Siberia into Alaska across the Bering Straits. The usually quoted period of their migration is between 40,000 and 10,000 years ago. Since they were nomadic peoples, it is unlikely that they brought the knowledge of pottery making with them. When pottery making did begin, it was fundamentally unlike any known work from the Old World and the few remote resemblances to Oriental motifs are almost certainly fortuitous. The wheel remained unknown until the arrival of Europeans, although there is reason to think that a turntable or "slow" wheel may have been used occasionally. Most of the pottery was made by coiling, which is so obvious a method that even young children

sometimes use it without tuition; there is therefore no need to assume Asiatic influence. Molding was used for certain vessels but, like coiling, this technique undoubtedly could have arisen spontaneously. It is therefore probable that the art of pottery developed in complete isolation. It is likely that most of the work was done by women. This is nearly always the case when the wheel is not used, and furthermore Pueblo Indian women still do this kind of work.

Slips were used to cover the body, and coloured slips provided the material for much of the painted freehand decoration. Glazes are rare although examples can be found among the Pueblo Indians of New Mexico from about A.D. 1300 onward, on a few vessels from the Chimú area in the Andes, and occasionally in Central America. The effect of a "reducing" atmosphere was understood, so that gray and black pots are found as well as the red and brown ones which were fired in an oxidizing flame. Undecorated surfaces were often highly polished.

North America.—The most important North American pottery was made in the southwest—an area which includes Arizona, New Mexico, and parts of Utah and Colorado. The people who inhabited the plateau land from about 100 B.C. are often referred to as the Anasazi, a Navaho Indian word meaning "ancient people." They are the ancestors of the Pueblo who began to emerge about A.D. 700. The Anasazi were nomadic hunters and although they did not make pottery, they did make excellent baskets. Fixed dwellings appear about A.D. 50, and this probably marks the beginning of pottery manufacture. The earliest pots were probably baskets smeared with clay and dried in the sun. Next came basket-shaped wares coiled in a gray body. These were used principally for cooking. They were followed by more decorative bowls and pots with striking black-and-white geometric designs which seem to have been executed about A.D. 700. Slightly later there is another type of ware which has black decoration on a red slip. After the 12th century the earlier types began to dis-

There is little pottery of importance from other parts of the United States. Primitive pots have been found on the Atlantic coast, in Georgia and Florida, on the Gulf Coast, and elsewhere, some of which are based on basketwork. Geometric decoration, usually incised, is the rule. Eskimo pottery, which is generally rather crude, bears some resemblance to early Asiatic types.

Central America.—The pottery of Mexico and the rest of Central America is of considerable interest but the wares are so diverse that it is impossible to summarize them adequately. They probably date from the 2nd millennium B.C. onward and were made by the Mayas, the Zapotecs, the Toltecs, and the Aztecs. Generally speaking, geometric patterns are common, and slips in black, brown, white, or red were frequently used. A curious Central American technique somewhat resembles the *batik* method of dyeing textiles. The surface of the pot was first coated either with wax or gum. This was then scraped away in part to form a predetermined pattern, and the whole surface was covered with pigment. In firing, the gum burned away, leaving only the scraped parts in colour. This process may have been adopted from South America. Ornament carved in low relief after firing is to be seen occasionally and has few parallels outside the Americas. An unusual technique from the Mexican highlands consisted of covering the whole surface of the pot with a kind of thick slip, most of which was then scraped away leaving only thin partitions. These compartments were filled with slips of a contrasting colour. The commonest shapes are bowls and wide-mouthed vases; many of these were made with legs, usually three in number so that they could be set down on uneven ground. Figurines, which may be painted, are also found.

By about 600 B.C. the Mayas were making an excellent polychrome pottery in which designs in red and black were painted on a cream or orange slip. This was continued until about A.D. 1000. Between roughly the 4th and the 10th centuries A.D. the Zapotecs, whose chief ceremonial site was Monte Albán in Oaxaca State, made urns in the form of the gods which are extremely striking in appearance. An orange-coloured pottery, decorated in a great diversity of styles, is associated with the Toltecs, as is a dark-coloured pottery with a glossy appearance and incised ornament ("plumbate" ware). Both these types were widely distributed throughout Central America from the 11th to 14th centuries. Little is known of the Aztecs until about 1325, the date of the foundation of Tenochtitlán (Mexico City). Much of their pottery utilizes an orange-burning clay which was painted with black curvilinear geometric motifs in contrast to the earlier rectilinear style. During the period of Montezuma I in the 15th century, designs became more naturalistic, and birds, fish, and plant forms were freely used. European motifs appear after the conquest and such techniques as tin enameling were used from the 17th century onward. Examples can be seen in the Metropolitan Museum of Art, New York City, and elsewhere.

South America.—Most South American pottery was made at centres in the Andes and on the west coast, particularly in Bolivia and Peru. Pottery of lesser importance comes from Ecuador, Colombia, northwest Argentina, and northern Chile. In some places a very high degree of skill was attained, particularly in the central Andes where the earliest wares seem to date from the end of the 2nd millennium B.C. Much of the pottery was made in molds. A characteristic feature is the stirrup-shaped spout on many jars. The *batik* type of decoration already mentioned was also used. Vessels were modeled in the shape of animal or human figures, which were also used as motifs for painted decoration. The puma god worshipped by the early peoples appears in many forms.

The work of the Mochica (Mochica) culture which flourished around the northern coast of Peru is at its best about the 7th century A.D. Jars in the form of human heads, some of which may be portraits, are remarkable both for the naturalism of the treatment and the skill of the potter. These have the stirrup spout. Painted decoration is often stylized, but with a considerable degree of realism and the subjects are nearly always ceremonial or religious.

The pottery of the Nazcas who lived on the southern coast of Peru at much the same period is noted for its painting. A varied

(Left) Pueblo jar with black-and-white geometric design, from New Mexico. Height: 15 in. In the Museum of New Mexico. (Right) Hohokam storage jar with red-on-buff decoration, from southern Arizona. Height: 19½ in. In the Arizona State Museum

appear and were replaced by polychrome wares decorated with stylized birds, feathers, animals, and human figures amid the geometric patterns. The principal colours are yellow and red. A small quantity of glazed ware was made in the Zuni area of New Mexico.

The Hohokam tribes (a Pima word meaning "those who have gone") lived in the desert of southern Arizona, and were approximately contemporary with the Anasazi. They made pottery figures for religious purposes, usually of crudely modeled naked women. Some of this pottery is a gray ware, but most of it is buff with decoration in iron red which lacks the stiffness of the Pueblo designs.

The Mogollon culture of New Mexico produced, during the Mimbres period of the 11th and 12th centuries, a ware which is remarkable for its lively black-and-white decoration depicting human, animal, and insect forms in a much less stylized manner than the paintings on most other wares from the southwest.

palette included several shades of red and blue, yellow, orange, green, brown, black, gray, and white. The stirrup spout here becomes two spouts joined by a flat bridge. The earliest painting is on a red ground, white grounds becoming more common later. Geometric patterns are to be seen in conjunction with stylized birds, human heads, and the like. The naturalistic portrait jars of the Mochica do not appear, but there are some vessels in the form of figures modeled in a much more conventional style and characteristically painted. Puma's heads are often applied in relief with the body of the animal completed in brushwork. The centipede god is a motif which does not appear elsewhere.

The people of Tiahuanaco, who lived in the region around Lake Titicaca, were influenced by the Nazca wares though painted decoration, often carried out on a red slip ground, is more limited in colour than the Nazca types. The puma head was used as a motif and decoration generally is extremely stylized with a strong geometric flavour.

The Chimú culture succeeded the Mochica in the northern area and lasted until the arrival of the Incas. The most familiar ware is in a body which varies from gray to black, although a red polished ware, sometimes painted in white slip, was also made. The influence of the Mochica tradition can be seen in the retention of the stirrup spout on some jars; others have the double spout connected by a flat bridge. The modeled wares of the Mochica culture were also revived, but are generally inferior.

The Incas originally settled in Cuzco, the old capital of Peru at the end of the 11th century. During the 15th century they established themselves firmly over a wide area including the territory of the Chimús. They were principally soldiers and administrators with small inclination toward luxury and their pottery, particularly in the 15th century, is of excellent quality; being designed in good taste without an excess of decoration. Most Inca pottery is red polished ware. It is usually painted with geometric designs in red, white, and black, although relief decoration is also to be seen on black ware; especially from the Chimú region. The commonest surviving form has been called an aryballos, although its resemblance to the Greek form is remote and fortuitous. It has a conical base, and the neck finishes in a flaring mouth. Two loop handles are set low down on the body. The assumption that this vessel was made for carrying water on the back seems a little doubtful in view of its shape and the disposition of the handles. Little fine pottery was made after the arrival of the Spaniards in the 16th century.

2. The 17th and 18th Centuries.—We have little detailed information about the pottery made by the early European settlers in North America. Most of it was manufactured locally for local needs and from the clays that were nearest to hand. Since most of these contained iron in varying quantities, the pottery body burned to colours between buff and red. As kilns capable of reaching a high temperature were not constructed manufacture was limited to earthenware. Lead glazes were commonly used. Slips, both as a wash and as "trailed" decoration, were employed, and *sgraffito* decoration is known. Most of this pottery was made for practical rather than decorative purposes. A few potteries were established in the 17th century in Virginia, Massachusetts, and New Jersey, and German settlers started work in eastern Pennsylvania as early as 1735, making slip-painted and *sgraffito* ware in their own traditions.

Perhaps the most important development in colonial America took place in Savannah, Ga., where Andrew Duché, of Huguenot descent, started a pottery about 1730. He interested himself in the manufacture of porcelain and discovered the china clay (kaolin) and feldspathic rock (petuntse) necessary to its manufacture. By 1741 he appears to have made a successful true porcelain, but failed to gain adequate financial assistance to develop it. He therefore traveled to London, arriving in 1744, and endeavoured to sell the secret to Edward Heylyn and Thomas Frye, the founders of the Bow factory in London. Their interest is certain, since the patent specification subsequently filed specifically mentions *maker*, said to be the Cherokee name for china clay. Duché returned to Virginia by way of Plymouth and there spoke with William Cookworthy, later to be the first manufacturer of true porcelain in En-

gland. In the early 1760s it was still not known to what extent Duché actually manufactured porcelain, but the Cherokee clay was shipped to England from time to time during the 18th century, and the *Bristol Journal* for Nov. 24, 1764, refers to the import of some specimens of porcelain made in Georgia. There is little doubt, therefore, that the first porcelain to be made in an English-speaking country came from North America. Wedgwood imported several tons of Cherokee clay which was used in the development of the jasper body, and on June 12, 1760, a marker was placed on Highway 28, five miles north of Franklin, N.C., to mark the site of the pit and to commemorate Wedgwood's use of this clay.

By 1765 potteries were being established on a sufficient scale to

warrant an attempt to recruit workmen from Staffordshire. Wedgwood wrote at the time: "They had an agent amongst us hiring a number of our hands for establishment of new Potworks in South Carolina." As early as 1769 a workman named Gousse Bonnin, reputed to have come from the Bow factory, and a certain George Morris advertised porcelain for sale in Philadelphia, but manufacture appears to have ceased there in 1774. A specimen of Bonnin's work is in the Henry Francis du Pont Winterthur Museum at Winterthur, Del. Potteries for the manufacture of

creamware were also established in and around Philadelphia.

N. THE 19TH AND 20TH CENTURIES IN THE WEST

There is a fundamental difference between work done before the Industrial Revolution, the effect of which began to be felt in the ceramic industry before 1800, and that done subsequently. A student of the older wares, particularly those of the East, may find much of the later work difficult to accept because of its machine finish. When an object is made by hand it is never exactly the same as any other object; also the processes by which it has been formed and decorated are not disguised. Consider, for example, a Sung pot or a specimen of Japanese Tea Ceremony ware, whose so-called imperfections of finish by factory standards are an integral part of their beauty and character, or the glaze of a *Kuan* vase, which would lose its individuality if it possessed the smooth finish of a factory-made specimen. The technical precision of the 19th century, which made its products indistinguishable from one another, and the careful concealment of the means by which the end had been achieved, were both unprecedented and deleterious. Style and craftsmanship degenerated steadily in the factories and the situation was aggravated by the Great Exhibition of 1851 which encouraged manufacturers throughout Europe to vie with each other in producing wares which displayed virtuosity unhampered by questions of taste; for example, from as far afield as St. Petersburg, hitherto outside the mainstream of European development, there came some particularly hideous and colossal vases in a debased Neoclassical style—which, incidentally, were described by a contemporary writer as "second to few of the productions of Dresden and Sèvres for beauty of outline and perfection of finish."

It would, however, be unfair to blame only the factories for this degradation of taste; the citizens who bought their wares must bear some of the responsibility. Before the advent of mass communications in the 20th century, new fashions originated in the wealthiest stratum of society, which was usually the most cultivated, and filtered downward. An example of this process is the popularity of pottery figures in the outmoded Rococo style among the labouring classes in England in the late 18th and early 19th century. As a result of the political and economic effects of the Seven Years' War (1756-63), in combination with the beginning of the Industrial Revolution, the European bourgeoisie prospered

and their wealth enabled them to become patrons and arbiters of taste. Having little taste and fewer traditions, they were primarily interested in the arts as a method of display or as a "status symbol," and thus they demanded an excess of intricate and expensive ornament. In the Far East the same process of degeneration began at this time, at least partly as a result of the large number of export orders received. This pernicious influence was kept at bay by the emperor Ch'ien-lung, who stigmatized the English as cultural barbarians, but became much more pronounced in the 19th century. Similar tendencies may be seen in Japanese ceramics after 1853, when many factories worked almost entirely for export to the West in styles demanded by their customers.

1. Britain.—19th-Century Porcelain.—The Neoclassical style, which had been popular during the middle years of the 18th century, gradually lost its earlier simplicity. In France the rise of Napoleon brought in its train the ostentatious Empire style, which was copied, for the most part, from the decorative art of imperial Rome and had some influence in England during the Regency period (1811–20). It is noticeable on the porcelain vases made at Worcester, Derby, Rockingham, and elsewhere. These were often decorated with well-painted topographical subjects which were no longer confined by frames but ran round the vase as a continuous landscape. Flower painting was often of excellent quality and was much influenced by the work of William Billingsley, a flower painter who worked at Derby toward the end of the 18th century and who later started a factory of his own at Nantgarw, Glamorgan. It seems likely that he received his soft porcelain formula from Zachariah Boreman, a Chelsea workman who had become a landscape painter of note at Derby. His porcelain was, perhaps, the last survival of the 18th-century tradition and was much used by London decorating establishments for work in the style of Sèvres.

At Worcester a factory which had been established by Robert Chamberlain in 1786 produced porcelain decorated in a debased Japanese style. Because of its gaudy colour—iron red and underglaze blue coupled with lavish gilding—it is sometimes called the "thunder and lightning" pattern by collectors. Similar "Japan" patterns were being employed at Derby and at the Worcester Royal Porcelain Factory although much of the work of the latter was more restrained. Some of the best painting at the old factory at Worcester was executed by Thomas Baxter, who used marine shells as a subject, and by the figure painter James Pennington.

It has been said, unfairly, that Josiah Wedgwood (*q.v.*), by developing the factory system, was largely responsible for the degradation of the ceramic art; Wedgwood wares have usually been in good taste even if they have not always been particularly adventurous. A far more malign influence was that of John Rose of Coalport (Salop), who took over the virtually bankrupt Nantgarw factory in 1819. Rose admired the work of Sèvres and proceeded to imitate it, buying or borrowing specimens to copy and using such ground colours as the *rose Pompadour*, which became popular under the inaccurate name of *rose du Barry*. He was one of the first English exponents of the revived Rococo style, which appeared about 1830, and made much porcelain encrusted with applied flowers. His work has been erroneously regarded as a close copy of Sèvres. Rose is also said to have made some copies of Chelsea, notably of the "Goat and Bee" jugs, and of tureens in the form of vegetables, principally cabbages. Coalport flower painting, however, is very fine in quality and much in the style of Billingsley, who actually worked at the factory for some years, although it would be dangerous to attribute any surviving work to his hand.

Josiah Spode the second invented bone china about 1800 and at first made good use of it. Some of his later wares became increasingly pretentious copies of French styles with highly coloured grounds, lavish gilding, and an excess of applied ornament. The factory was taken over in 1833 by William Taylor Copeland, Jr., whose father had been in partnership with Spode, and was amalgamated with Wedgwood in 1964.

The firm of Minton's was founded at Stoke-on-Trent in 1793 by Thomas Minton, a Caughley engraver said to have devised for Spode the Broseley Blue Dragon and Willow patterns which are still in use. Like Coalport, the factory was much occupied in copy-

ing the work of Sèvres. From 1848 to 1895 they employed a Frenchman, Joseph François Léon Arnoux, as art director and under his tutelage French artists were brought to England; for example, the sculptor Albert Carrier-Belleuse and also Marc Louis Solon, who was responsible for introducing *pâte-sur-pâte* decoration into England (*see below*).

The Derby tradition of fine painting was carried into the 19th century during which time the flower designs became somewhat overblown although landscapes remained on a high level. The sets of so-called *Campana* vases (more properly *Campagna*), distantly derived from Italianate copies of the Greek *krater*, were often decorated with landscapes by the brothers Robert and John Brewer, and others. The Brewers were pupils of the topographical painter Paul Sandby whose exact and realistic style also influenced Boreman. A colourful character, "Quaker" Pegg, produced some meticulous botanical representations of flowers because his Puritan conscience forbade anything more decorative. Thomas Steele painted fruit and flowers, sometimes on porcelain plaques intended for framing—a singular misuse of porcelain copied from Paris and Vienna.

About 1840 the Parian body, an imitation of Sèvres biscuit porcelain, was introduced by Copeland and Garrett (formerly Spode) and a great many figures, some of them extremely large, were made in this medium. Most of them are either sentimental subjects or quasi-erotic nudes such as were popular in Victorian art. A specialist in the latter mode was Thomas Bott of Worcester whose nudes, painted in white enamel on a deep blue ground, were intended to imitate the earlier Limoges enamels on copper. Parian ware had some success in America where it was manufactured by Norton and Fenton.

19th-Century Stoneware and Earthenware.—Side by side with

these developments in the manufacture of porcelain, the production of earthenware and stoneware for the cheaper market continued on an ever-increasing scale. Lustre decoration which had been revived in the preceding century was used more frequently than before. A type of stoneware obviously inspired by Wedgwood's jasper ware was made at Castleford, in Yorkshire. "Ironstone" china, a type of opaque stoneware sometimes called "opaque porcelain," was introduced early in the 19th century. Its development is usually credited to Miles Mason, although the patent granted to Turners of Lane End, Staffordshire, in 1800 may have been the starting point. Pseudo-Chinese and "Japan" patterns were frequently used to decorate it.

By 1830 new underglaze colours had been pressed into service for transfer printing. These new colours were particularly used by Ridgway and Co. of Hanley, Staffordshire. Transfer-printed earthenware in blue, which became increasingly popular after 1810, was soon being produced in enormous quantities. It was much used by Spode, who often used American subjects for wares exported to the United States; these are now prized by collectors. Polychrome transfer printing, essayed tentatively at Liverpool during the 1760s, was also mastered.

Earthenware figures were made in large quantities in Staffordshire and elsewhere, the best being associated with Enoch Wood. They were intended as chimney ornaments, and the subjects range

from bullbaiting to sentimental shepherdesses. Many of them are copied more or less directly from Derby porcelain figures, and they are a sad but accurate reflection of the times during which they were made.

The Great Exhibition completed the degeneration which had been started by the revival of the Rococo style. Technical progress allowed the manufacturers ever-increasing elaborations with which they bludgeoned the few remaining sensibilities of their customers. Past styles were indiscriminately and clumsily copied. Minton's made an earthenware decorated with coloured glazes which they misnamed *maiolica*. It was used not only for decorative wares but for other domestic articles—even umbrella stands—and for architectural purposes. At Minton's, too, Palissy's work was badly imitated and Charles Toft, one of the modelers, laboured to produce copies of the *Henri Deux* ware of Saint-Porchaire—surely the least rewarding of all such derivations.

The Paris exhibitions of 1867 and 1878 brought Japanese pottery and porcelain once more to the attention of European manufacturers, but it was not the superb porcelain of Arita which had had so much influence in the previous century. This time the Japanese exported cream-coloured earthenware with a closely crackled surface and lavish painting of poor quality, rightly judging that it would appeal to Western taste. It became extremely popular under the name of "Satsuma" and was copied avidly at Worcester and elsewhere. Gothic wares, distantly echoing some of the old Rhineland stonewares, were made by Meigh and Co. at Hanley, Staffordshire, and, as Geoffrey Bemrose has remarked in his admirable survey of 19th-century wares (see *Bibliography*, below), it is surprising that no enterprising firm thought of giving the world pottery designs in Japanese Gothic as had been done in furniture.

By 1860 a few people had become profoundly disturbed by the level to which popular taste had sunk. Among them was William Morris (*q.v.*), who founded a firm of interior decorators and manufacturers in 1861. One of his pupils, William de Morgan, started a pottery at Fulham (London) in 1888 and made dishes and tiles inspired by Persian, Hispano-Moresque, and Italian wares. De Morgan used brilliant blues and greens and a coppery red pigment. His designs are a great improvement on those of the factories, although they are still derivative.

After about 1860 Doultons of Lambeth (London) copied 18th-century brown stoneware, making small figures and repeating earlier designs. The incised decoration by Hannah Barlow is both pleasant and competent. From a Fulham pottery owned by the brothers Martin came grotesque and often amusing stoneware vases which were sometimes decorated with coloured slips.

20th Century.—In the early part of the 20th century Bernard Moore experimented with Chinese glazes, producing some successful *flambé* and *sang de boeuf* glazes on a stoneware body at his small factory in Stoke-on-Trent. He worked in association with William Burton of Pilkington pottery in Manchester, which also made experimental decorative ware of all kinds.

The fact that increasing attention was being paid to ceramics is shown by the opening of the Omega workshops in 1913 by the art critic Roger Fry. This promising venture failed because of lack of trade during World War I and closed in 1919.

The artist-potter has had an important influence on modern design from the time that Bernard Leach (1887–) established the St. Ives pottery in 1920. Leach spent many of his early years in the Far East and learned the art of making *raku* and stoneware

in Japan. He began working at a time when interest in early Chinese wares had greatly increased and much of his work is obviously influenced by the work of Tz' u Chou as well as that of Japan. It is, nevertheless, strongly individual. One of Leach's pupils, Michael Cardew, has done good work in stoneware, which he often decorates with vigorous patterns drawn with a pleasing economy of outline. William Staite Murray, at one time the head of the ceramic department of the Royal College of Art, has made some important and interesting stoneware and has influenced many younger potters. Excellent work has been done by continental potters working in England, among them Lucie Rie from Vienna and by Hans Coper. Amusing figures have come from Marion Morris who was trained in Budapest.

Development after World War II was much hindered by a heavy purchase tax on ceramics. Its relaxation in the early 1950s allowed the movement to resume its progress. By the 1960s many art schools included pottery making in their curriculum and students were rapidly increasing in numbers.

Design in factory-made wares has improved considerably. The work of Wedgwood, in particular, deserves mention. During the 19th century, Wedgwood wares, exemplifying the value of a sound tradition, had always been in better taste than that of their contemporaries. Bone china was made between 1812 and 1816, and manufacture was revived in 1878. A noted decorator of creamware in the mid-19th century was the French artist Émile Lessore. Jasper ware was unpopular for a short period during the first half of the 19th century, but it was revived with success in 1850, when some busts of contemporary celebrities in black basaltes were done by the sculptor C. F. Wyon, and has been made ever since. At the beginning of the 20th century the factory extended its already considerable business in the United States and a service of nearly 1,300 pieces was supplied to the White House during the presidency of Theodore Roosevelt (1901–09).

BY COURTESY OF BERNARD LEACH

STONEWARE COVERED BOWL BY BERNARD LEACH; ENGLISH, 1950. ST. IVES, CORNWALL. DIAMETER: 12 in.

Between 1918 and 1939 Keith Murray and Eric Ravilious did excellent work in keeping Wedgwood design at a high level, and their work was continued by Victor Skellern, who became art director in 1935. In 1936 the factory moved to its present site at Barlaston, Staffordshire, when the historic site at Etruria, Staffordshire, was abandoned, and it is now one of the most modern in the world. As with most other

firms, both the factory and the museum can be visited by the public by appointment.

A new development in decorative porcelain is to be seen in the designs of Dorothy Doughty for the Worcester Royal Porcelain Company in England, and in those of Edward Marshall Boehm at Trenton, N.J. Characteristic of this kind of work are the American birds of Dorothy Doughty issued in limited editions by the Worcester Company. These are especially remarkable for technical advances in preparing the article for firing, which allow the material to be treated with much greater freedom than hitherto. Porcelain becomes very soft when it reaches the point of vitrification but, using an elaborate series of props to support free-floating parts, the Worcester technicians having succeeded in firing designs which would have been completely impossible earlier. Associated with these models are exact reproductions of natural flowers which also excel in complexity anything which has been made in the past.

2. The European Continent.—In the 19th century Meissen and Sèvres continued to be the two principal factories and leaders of fashion, although at both places, as elsewhere, artistic standards declined considerably.

Meissen.—At the end of the 18th century Meissen was in grave financial difficulties and its situation was aggravated after Dresden was bombarded in 1813 in the course of the Napoleonic Wars. For some years afterward it struggled along producing wares in a version of the Empire style which is also reflected in the ornate and cumbersome lines of the Biedermeier period (see NINETEENTH-CENTURY ART).

Later, the revived Rococo style was adopted under the chief modeler Ernst August Leuteritz, and a large export trade with England was renewed. This was the period of the sentimental Dresden shepherdess, formerly much admired in England and the United States, to the neglect of German figures made during the early 18th century. Heinrich Gottlob Kühn, who was appointed director in 1849, restored much of the factory's former prosperity, and it was moved from the old Schloss Albrechtsburg to the present site at Triebischtal in 1860. Productions during this period include large and ornate candelabra, overdecorated mirror frames, clock cases, and the like, as well as vases and tureens based on the old Rococo models.

From about 1870 styles altered somewhat and are afterward referred to as those of *die Neuzeit* ("the New Period"). Some of the figures and groups illustrating contemporary subjects throw an amusing sidelight on manners and customs of the time. Meissen celebrated its bicentenary in 1910 with a massive illustrated history of the factory by K. Berling (see *Bibliography*).

After World War I, advances were made under the directorate of Adolf Pfeiffer, and figure modeling worthy of the old tradition was done by Paul Scheurich, Max Esser, Paul Börner, and others. The early red stoneware was also revived. This renaissance was halted temporarily by World War II, but production had been resumed by 1950. In the early 1960s the wares which were being exported from the German Democratic Republic into western Europe were excellent in quality.

Sèvres.—In the early part of the 19th century the gaudy Empire style was current. As a result of Napoleon's campaign in Egypt and the newly aroused interest in that country, the style incorporated many Egyptian motifs which were somewhat incongruously translated into porcelain. Also many porcelain plaques with minutely detailed enamel painting in imitation of easel pictures were executed during the first decades of the century. In 1804 the new director, Alexandre Brongniart, discontinued the

manufacture of soft paste which was, however, revived under Ebelen in the middle of the century. The later soft paste is decorated in the old styles, a turquoise-blue ground in conjunction with flower painting in reserved panels being especially common.

Technical improvements include the introduction, in about 1855, of *pâte-sur-pâte*, a process later popular in England and particularly at Minton's. The design was painted in white slip on to a surface of coloured, lightly-fired clay. Each coat of slip was allowed to dry, and another superimposed upon it, until the desired degree of relief had been attained. Finally it was scraped, smoothed, and incised by metal tools and the whole object glazed and fired.

The sculptor Albert Carrier-Belleuse was appointed art director in 1876 and, at about the same time, Oriental porcelain was freely imitated and experiments with *flambé* glazes undertaken. Théodore Deck, who influenced the work of Bernard Moore in England, became director in 1887. He introduced a variety of soft porcelain and promoted the use of stoneware for architectural purposes. Many new underglaze colours were also introduced. The sculptor Auguste Rodin was employed at Sèvres for a short time but does not seem to have left any enduring marks of his presence. Artistically speaking, Sèvres ware has not been very distinguished since the 18th century. The factory possesses an excellent museum of French ceramic art.

Other Continental Factories.—The Royal Porcelain works at Copenhagen has made a great deal of porcelain with simple patterns in underglaze blue derived from Chinese sources by way of Meissen. Molded fluted shapes are characteristic. The well-known biscuit figures after the sculptor Bertel Thorvaldsen (1768–1844) were not produced until 1867, and the factory later introduced a slightly amber-coloured biscuit which was used for figure modeling by A. Malinowski and others. Painting on a grayish-toned crackled glaze led to experiments with celadons since, technically, the two have much in common. Other glazes inspired by early Chinese work followed. The firm of Bing and Gröndahl was established in 1853, and excellent and imaginative work has been done there. In later years, too, such factories as that of Rörstrand in Sweden and Arabia Oy. in Finland have achieved a growing reputation for excellent design in the modern idiom.

A factory which has preserved its traditional reputation for fine porcelain is that of Nymphenburg, at Munich, now the Staatliche Porzellan-Manufaktur Nymphenburg. After many vicissitudes in the early part of the 19th century, it was taken over by Albert Bäuml, and under his able directorship the factory was put on a sound commercial basis. At the beginning of the 20th century, it began to use a wider range of underglaze colours with the aid of colour-chemists from Sèvres and, about the same time, reissued some of the old figures and services of Bustelli and Auliczek which are appropriately marked. Attention was soon turned to services of fine quality in the modern idiom, and excellent figures by Resl Lechner and others were produced. The former artist succeeded in adapting the 18th-century styles to 20th-century purposes in a manner which is an object lesson to those manufacturers who insist, even today, in adding the scrolls and flourishes of the Rococo.

In this brief discussion it is impossible to describe in detail the work of the artist-potters on the continent. They tend to be less conservative than their English counterparts and many new and interesting developments have occurred. The modern fashion for

abstraction in art is particularly favourable to development, since the potter understood its principles long before the 20th-century artist came to it. (G. Se.)

3. The United States.—Although Andrew Duché had succeeded in making porcelain as early as 1741, the first man to produce porcelain in any quantity was William Elias Tucker of Philadelphia. At first he was a decorator of whiteware, but started to manufacture both creamware and bone china about 1826. Judge Joseph Hemphill became a partner in 1832, and workmen were imported from Europe. Copies of Sèvres porcelain and other European wares were made about this time in a fine white porcelain body. The first factory at Bennington, Vt., was founded by Capt. John Norton in 1793. He made domestic wares, including salt-glazed stoneware. The factory was removed to Bennington Village by his son, Judge Lyman Norton, in 1831, and creamware and a brown-glazed ware were produced. In 1839 the factory became Norton and Fenton and later the manufacture of Parian ware began. This unglazed near-white soft porcelain named after Parian marble had been first made in England by Copeland and Garrett. John Harrison of Copeland's was employed and brought with him a number of molds. An ironstone china called graniteware or white granite was also made.

The East Liverpool, O., industry was established in 1838 by James Bennet, an English potter. The first products made there were "Rockingham" and yellow-glazed ware. In the decade following the Civil War, William Bloor, Isaac Watts Knowles, and others introduced the production of whiteware. By the last decade of the 19th century production had grown until it was the largest pottery-producing area in the world.

At about the same time Zanesville, O., was developing as a pottery centre. First production was salt-and-slip-glazed stoneware. At a later date much artware was produced in plants operated by Samuel Weller, J. B. Owens, George Young, and others. Zanesville artware established the basis for a sizable modern interest in collecting. Another important centre during the 19th century was located at Trenton, N.J., where the first factory was established in 1852. Connected with it was William Bloor, who had some responsibility for putting the industry on a successful footing in East Liverpool. Trenton, like East Liverpool, produced fine, skilfully decorated whiteware.

A close study of the technical side of manufacture was not undertaken until Edward Orton, Jr., succeeded in getting support for the establishment of a department of ceramics at Ohio State University in Columbus in 1894. The New York State College of Ceramics at Alfred, N.Y., was started soon afterward with Charles F. Binns as its director. Binns was a member of an English family connected with the manufacture of porcelain at Worcester and Derby during the 19th century, and had himself held a supervisory position at Worcester. Similar departments were added to other universities soon afterward, and Orton took the lead in forming the American Ceramic Society in 1898. In this way knowledge was put on a more scientific basis, and the trained ceramists who soon became available to the industry were responsible for many technical improvements. Nevertheless, the artistic direction of the factories did not reach a high standard.

Toward the end of the century it became fashionable for American women to study the art of painting on European pottery and the Cincinnati Pottery Club was founded in 1879 to promote sound pottery design. As a result of its work, the Rookwood Pottery was established in 1880 by Maria Longworth Storer. Rookwood wares show a distinct Japanese influence and have excellent red and yellowish-brown glazes.

The National Ceramic Association was organized in Chicago in 1891 for much the same purpose as the Cincinnati Pottery Club. The National League of Mineral Painters, founded by S. S. Frackelton of Milwaukee, Wis., encouraged the art of enameling on pottery. The American Ceramic Society came into existence in 1898.

The most important regular exhibition is organized and circulated biennially by the Everson Museum of Art. It was originated by its predecessor, the Syracuse Museum of Fine Arts, in 1932 as the Robineau Memorial Ceramic Exhibition and held annually,

excepting the war years, until 1952. These exhibitions have been instrumental in making American pottery more widely known in Europe.

The pottery and porcelain of the United States now bears comparison with that of any other country, and standards are constantly improving. Technically, the U.S. is perhaps ahead of the rest of the world. The growing appreciation of good ceramic design has led national, state, and local governments to sponsor pottery making as an art. There is also a ceramic experimental station in the Tennessee Valley. Meanwhile the number of enthusiasts who collect early wares from other parts of the world is steadily increasing. Many important private collections are now in the United States and significant contributions have been made to scholarship. (M. M. F.; G. Se.)

III. MODERN MANUFACTURING TECHNIQUES

1. Composition and Preparation of Clay.—Clay is formed by the gradual decomposition of feldspar, a crystalline mineral which is the chief constituent of igneous rocks, for example granite and gneiss. Feldspar contains alumina and silica in combination with another metallic oxide, usually that of potassium. Over very long periods it decomposes into true clay, or kaolinite (*q.v.*) as a result of mechanical disintegration together with the chemical action of carbonic acid and water. These conditions are most often found where rock has been kept from contact with atmospheric oxygen by overlying marshland.

Raw clay consists primarily of true clay particles and undecomposed feldspar mixed with other components of the igneous rocks from which it was derived, usually appreciable quantities of quartz and small quantities of mica, iron oxides, and other substances. The composition, and thus the behaviour and plasticity of clays from different sources, is therefore slightly different. The composition of a fine white clay, known as china clay or kaolin, is approximately as follows: silica 50%, alumina 33%, iron oxides 2%, magnesia 1%, alkali 2%, water 12%. At the start of the manufacturing process coarse clays are washed with water or "levigated," a process which separates the gross particles but not the particles of quartz and feldspar of a similar weight. Washing has no effect on finer clays.

Kaolin is the only type of clay which yields a white material when fired. Porcelain is made from kaolin mixed with fusible rocks, such as feldspar and silicas. When the mixture is raised to a high temperature it "vitrifies" or fuses to form a glasslike substance; if heated still further it becomes translucent. For example, porcelain composed of 50% clay, 50% feldspar will vitrify at 1,200° C, become translucent at 1,250° C, and will melt completely at 1,400° C. (Porcelain manufacture is discussed in detail in the article CHINAWARE.)

Earthenware is not vitrified; it is fired only to the temperature where point-to-point attachment of particles occurs and in consequence remains porous. Earthenware bodies are made by mixing plastic clays with flint and feldspar. In the mid-20th century in England ball clay, common in Devon, is included for its plasticity. It is grayish blue in colour, and becomes white when fired at a moderate temperature. The proportions of the constituents vary according to the purpose for which the body is required, but a typical example is as follows: blue ball clay 43%, china clay 24%, flint 23%, pegmatite 10%. The firing temperature of such a body would be in the region of 1,150° C; that of softer varieties of earthenware about 1,000° C.

Stoneware is fired to the point of vitrification, but not to that of translucency, although overfired specimens may be slightly translucent if they are also thin. Its constituents are similar to those of earthenware, a typical example consisting of 30% ball clay, 32% china clay, 15% flint, and 23% Cornish stone. Vitrifiable clays, which naturally contain fluxes such as alkali and lime, are used when they are available, but they often need additional silica without which they tend to collapse in the kiln. Stoneware bodies vitrify at between 1,000° and 1,200° C according to their composition.

The function of the flint is to "open" the material, preventing cracking and warping during firing. Being itself a refractory mat-

terial it is unaffected by the temperature. It is added to the mixture in the form of a fine powder which is achieved by heating and then quenching the material when it becomes white and easily crushed. The feldspar, which acts as a flux (a substance which lowers the vitrification temperature), is usually added in the form of Cornish stone or pegmatite. Like the flint it must be very carefully ground. If the particle size is small, its fluxing property is increased while deformation during firing becomes increasingly likely. If, however, the particle size is too great, the porosity of the ware is increased. The raw material is therefore carefully sieved before being added to the mixture.

Before mechanization the clay was prepared for use by exposing it to the disintegrating action of sun, rain, and frost ("weathering"). It is now broken down, mixed, and made homogeneous by machines such as the de-airing pugmill. This blends the clay and also frees it from air pockets by shredding it into thin strips in a vacuum: in the past small pockets of air were often left in the clay and as they expanded when heated, they left cavities in the body after firing, causing the so-called "moons"—patches of greater translucency—to be seen in some early European porcelains. Another innovation is the use of magnetic devices to remove gross particles of iron from the clay. The body is finally diluted to the consistency of slip from which the excess water and gross impurities are removed by filter presses.

2. Shaping the Clay.—Earthenware bodies are usually extremely plastic and can be shaped by many methods. Porcelain and stoneware bodies are usually less plastic, and sometimes present difficulties which have to be overcome in various ways. The methods in use before the advent of mass production have been already discussed (see *Introduction*, above). Both throwing on the wheel and slip casting are still used, but not to the same extent as formerly. The jolly, introduced during the 18th century, is much used for making cups and circular plates. It is similar to the wheel in appearance except that the head consists of a plaster mold. As it revolves, the interior of the plate is shaped by pressing the clay against the head, while the exterior, including the foot-ring, is shaped by a profile brought into contact with the clay. Machines which make both cups and plates automatically on this principle have now been introduced. Small parts, such as cup handles, are made separately by pressing clay into molds, and are subsequently attached to the vessel by "luting," the term used when clay slip is used as an adhesive. Extrusion, which consists of pressing the clay body through a shaped mouthpiece (like toothpaste from a tube) is used in brickmaking and for pipes, rods, and so forth. Pressing with steel dies is becoming more common; the body can be in a wet, semiwet, or dry state.

Lathe turning, which can only be used when the article has dried to "leather" hardness, is occasionally employed for finishing touches such as grooving and undercutting. Like most hand op-

erations, it was tending to disappear in the early 1960s except on the more ornamental and expensive objects.

3. Drying and Firing.—Newly shaped articles were formerly allowed to dry slowly in the atmosphere. This stage has now been speeded up by the introduction of automatic dryers, often in the form of hot, dry tunnels through which the ware passes on a conveyor belt. Infrared dryers have been particularly used in the United States. Another method, which has found some application in the making of porcelain insulators and similar equipment for the electrical industry, is to expose the clay to a rapidly alternating electric field ("high-frequency" drying).

Kilns, too, are no longer the coal- or wood-fired ovens which were once universal. In England the disappearance of such fuels has been accelerated by the institution of "smokeless zones." Both gas and electricity are now used as fuels and although coal is still employed, its disappearance is only a matter of time. Many improvements have been made in the design of "intermittent" kilns, in which the ware is stacked when cold and then raised to the desired temperature. However, they remain extravagant on fuel and are awkward to fill or empty if they have not had time to cool completely. For these reasons they are being replaced by "continuous" kilns, the most economical and successful of which is the tunnel kiln. The wares are conveyed slowly from a comparatively cool region at the entrance to the full heat in the centre. As they approach the exit after firing they cool gradually. These kilns were developed independently in Germany and the United States at the end of the 19th century, and by the mid-1960s had been installed by almost all of the larger factories. Normally they burn either coal- or producer-gas or oil, but coal is used occasionally.

In the U.S., natural gas is more plentiful than in Europe and is often employed as an alternative fuel, particularly during the summer as the price is lower than in the winter. Electricity is being increasingly used and has many advantages, although it is costly unless the factory is close to a source of hydroelectric power. It is often used for small kilns, and for tunnel kilns in which glaze and decoration are fired on. Wedgwood's factory at Barlaston, Staffordshire, is now operated entirely by electricity, and the traditional soot-laden atmosphere of Staffordshire is beginning to disappear.

Since the success of the firing operation depends upon the kiln temperature, exact methods of ascertaining and controlling it are essential. In early times this depended on the skill of the kiln-master who removed a small plug from the kiln and judged the temperature by the colour of the glowing interior—the whiter the glow, the higher the temperature. Empirical methods of this kind have been replaced by devices such as the Seger cone invented by Seger of the Staatliche Porzellan-Manufaktur, Berlin. These are small three-sided cones made of ceramic materials which soften

MANUFACTURING TECHNIQUES

(Left) Throwing, or shaping, on a potter's wheel. This method, which has remained essentially unchanged for 5,000 years, is still used but not to the same extent as in the past. (Centre) Transfer printing. Pottery is often decorated by transfers taken from an engraved copper plate. (Right) Decoration. The application of small, molded ornament to the ledge of a plate is being done by hand.

BY COURTESY OF JOSIAH WEDGWOOD & SONS LTD., BARLASTON, STAFFORDSHIRE

and bend over at known temperatures. Several cones, each made to bend or "squat" at a different degree of heat, are set side by side and watched through a plug in the kiln wall. As the intervals between the temperatures registered by the cones are arranged so that they are in the region of 20°–30° C the heat of the kiln can be gauged with considerable accuracy. In the U.S. Orton cones replace Seger cones. They are similar in principle but register a different set of temperatures.

4. Decoration.—Glazes.—Until the 20th century, glazes were similar in composition to lead glass or soda glass. The usual method of application was to grind the glass to a fine powder and to make a suspension of the particles in water. The fired object was then dipped into the mixture, and the fine particles covering the surface fused into an amorphous, glasslike layer during a second firing, which was at a lower temperature than that used to fire the body. The most common practice is to spray the object with glaze material, although the older method is still practised occasionally.

Some fusion usually occurs between glaze and body and it is therefore essential that both should shrink by the same proportion and at the same rate on cooling. If there is a discrepancy, the glaze will either develop a network of fine cracks, or will peel off altogether. This "crazing" of the glaze sometimes develops at the time of manufacture, but sometimes many weeks afterward. It has been used decoratively by the Chinese.

The disadvantage of lead glazes is that very poisonous lead compounds are evolved during firing. (After firing such glazes are, of course, quite harmless.) Safe ways of handling this substance have been developed, but leadless glazes, the first of which was developed in England about 1820, are now the more frequently used in commercial production.

Fluxes are added to glazes to lower the melting point, since it is essential that this should not approach or exceed the firing temperature of the body.

Matt and semiopaque glazes are achieved by using materials—for example, certain silicates—which tend to crystallize. These can be very decorative. The substance first used to opacify glaze was stannic oxide, which yields a completely opaque, glossy white glaze. This process, known as tin enameling, has had great influence on the development of ceramic art. Bone ash (calcium phosphate) also acts in the same way when added to glaze material and, in modern times, zirconium oxide and antimony oxide have been used for this purpose.

Patterns.—Rubber stamps, inked with ceramic colours, are used to apply simple decoration and trademarks. Transfers from copper plates, introduced during the 18th century, are still in common use, as are lithographic and other processes, for example silk-screen printing, which consists of rubbing the colour through a patterned screen of textile material. Methods of decorating by hand differ little from those of earlier times but they are rarely practised because the high cost of labour makes them expensive and skilled workmen are now almost unobtainable. For the most part, uninformed public taste is satisfied by monotonous mechanical methods of decoration; indeed hand-painted wares are sometimes rejected as incompetent because the result is less precise than mechanical decoration.

5. Industrial Uses.—In the 20th century ceramics, especially stoneware and porcelain, have become much more widely used in industry. The electrical industry, in particular, is dependent on the porcelain factories for supplies of equipment. Porcelain insulators, for example, are used in domestic power plugs, transformers, and overhead lines. The fact that ceramics can withstand an intense degree of heat has led to experiments with mixtures of metallic and ceramic substances in certain parts of gas turbines and rocket motors. Similar mixtures have been applied to metal components as a protective layer against the corrosive effect of gases at high temperatures. Developments in this particular field are undoubtedly in their infancy.

POTTHAST, AUGUST (1824-1898), German historian who compiled the monumental *Bibliotheca historica medii aevi* (1862, 1868; new enlarged edition, 1895-96), a guide to the sources of European history in the Middle Ages. The work, in the form of an index, gives particulars of practically all the historical writers of Europe and their work between 375 and 1500. Potthast was born at Höxter on Aug. 13, 1824. He assisted G. H. Pertz (q.v.), the editor of the *Monumenta Germaniae historica*, and edited the *Regesta pontificum romanorum, 1198-1304* (1874-75). From 1874 to 1894 he was librarian of the German Reichstag. He died on Feb. 13, 1898, at Leobschütz.

POTTO, the name for small primates of forested areas of equatorial Africa. In common with the lorises, which they resemble, pottos are slow-moving tree dwellers that forage about at night in search of fruit, insects, and any small animals they can creep up on. Their deliberate pace is quickened only in emergencies. Pottos have large, staring eyes, stubble second fingers and second toes, and a peculiar ridge of spines formed of extensions of the backbone. The common pottos (*Perodicticus*), squirrel sized, with round faces, grizzled brownish fur, and a furry tail, are reputed to have the strongest hand grip of any animal their size. The smaller Calabar or golden pottos, also called angwantibos (*Arctocebus*), have stubby tails concealed in fur and smaller eyes closer set on a foxy face. See PRIMATES: Lemurs.

POTTSTOWN, a borough of Montgomery County, Pa., U.S., on the Schuylkill River, about 38 mi. NW of Philadelphia, is the trading centre for a prosperous farm, dairy, and industrial region. Hill School, a college-preparatory school for boys, is located there. The borough has a council-manager form of government, in effect since 1945. Steel fabricators and the manufacture of tires, tubes, and related products are the largest industries. Other manufactures include universal joints and axles, pipe fittings, gray iron castings, boilers, dresses and shirts, dairy and bakery products, paper boxes, and clay and concrete pipes.

In the immediate area of Pottstown iron was manufactured by 1717. The first cold-blast iron furnace in America was erected by Thomas Potts and Thomas Rutter in 1720, and the Coventry forge produced the first commercial steel in Pennsylvania in 1732. The prosperity of Pottstown was based mainly on the production of iron and steel until about 1918, when fabrication replaced the reduction of ores.

John Potts, ironmaster and merchant, laid out the town in 1752 under the name of Pottsgrove. Arthur St. Clair was a resident of Pottsgrove when he was elected president of the Continental Congress. In 1815 the town was incorporated as the borough of Pottstown. For comparative population figures see table in PENNSYLVANIA: Population. (L. A. Gr.)

POTTSVILLE, a city of Pennsylvania, U.S., on the Schuylkill river, 93 mi. N.W. of Philadelphia; the seat of Schuylkill

county. It is a picturesque town at the gap of the Schuylkill river through Sharp mountain and has many narrow and extremely steep streets. The shopping centre is extensive and attractive, serving a retail-trade area with a population of more than 100,000. Pottsville is located on the southern edge of the Pennsylvania anthracite coal region, and after the opening of the Schuylkill canal in 1824 the prosperity of the city was closely related to anthracite prosperity. The steady decline of the anthracite industry in the mid-20th century brought problems of chronic unemployment and of loss in population. (For comparative population figures see table in PENNSYLVANIA: Population.) The Greater Pottsville Industrial Development corporation experienced some success in bringing new industries to the area. Besides extensive mining industries and railroad shops, manufactures produce aluminum extrusions, plastics, dresses and shirts, an assortment of steel products, shoes, beer, concrete products and paper boxes.

Permanent settlers came to the site of Pottsville about 1795 and soon established a furnace for the production of raw iron. John Pott acquired and expanded the local iron furnace and set the stage for an important iron and steel industry that lasted until the 1920s. He laid out the town of Pottsville in 1816. It was incorporated as a borough in 1828, became the county seat in 1851 and was chartered as a third-class city in 1911. In the 1860s and 1870s Pottsville was a rallying point of the Molly Maguires (q.v.).

(L. A. GR.)

POUGHKEEPSIE, a city of New York, U.S., on the east bank of the Hudson river, midway between New York city and Albany, the seat of Dutchess county, a rich dairy-farming area. The city is the shopping centre of the mid-Hudson valley and contains many diversified industries. Among the largest are an electronic business machines company, a dairy machinery company and a printing and lithographing company. Other manufactures include clothing, cigars, chemicals, cough drops and ball-bearings. Among the nationalities represented in the city are Italians, Poles, Irish, Germans and Dutch.

Vassar, a private college of liberal arts for women (founded 1861), has a cosmopolitan student body and a distinguished faculty. Its founder, Matthew Vassar, conceived the idea "to build and endow a college for young women which shall be to them what Yale and Harvard are to young men." The college was incorporated as Vassar Female college, but under the influence of the intrepid feminist Sarah J. Hale, editor of *Godey's Ladies Book*, "Female" was deleted in 1867. From 1925 Vassar has conducted a Summer Institute of Family and Community Living for parents and their children, social workers and teachers. Also in Poughkeepsie is the Dutchess Community college, a junior college affiliated with State University of New York, opened in 1958. Extensive medical facilities are offered at Vassar and St. Francis hospitals and at the Hudson River State hospital for mental illness.

The Hudson river near Poughkeepsie for many years was the scene of the annual Poughkeepsie regatta of the Intercollegiate Rowing association, one of the most famous rowing events in the world. Established in 1895, it was held annually until 1949 except for 1898 when it was at Saratoga lake and for 1917-19, 1933 and 1942-46, when no competition was held. In 1950 the regatta was moved from Poughkeepsie to Marietta, O., and later to Onondaga lake, Syracuse, N.Y. (see ROWING).

The name Poughkeepsie was derived from Indian words meaning "the reed-covered lodge by the little water place." The town was settled by the Dutch in 1687 and served as the capital of New York state temporarily in 1778. A thriving river port in the early 19th century, from which ships carried grain to New York, it suffered a decline after the completion of the Erie canal and turned to industry and commerce. Poughkeepsie was incorporated as a city in 1854 and in 1952 adopted the council-manager form of government.

For comparative population figures see table in NEW YORK: Population.

POULENC, FRANCIS (1899-1963), French composer whose work illustrates a sophisticated trend in French music after World War I, was born in Paris on Jan. 7, 1899. He studied the

piano with Ricardo Viñes and in 1917 produced *Rapsodie nègre* followed in 1918 by *Trois Mouvements Perpétuels* and the *Sonata* for piano duet, and in 1919 by songs on poems by Guillaume Apollinaire and Jean Cocteau. In 1920 he was one of the group known as "Les Six," sponsored by Cocteau and Erik Satie and including, besides Poulenc, Georges Auric, Darius Milhaud, Arthur Honegger, Germaine Tailleferre, and Louis Durey. (The name of the group was taken from an article, "The Five Russians, the Six Frenchmen, and Satie," by the critic Henri Collet, comparing the French composers with the Russians led by M. A. Balakirev, though they were not united by aesthetic affinities.)

From 1921 to 1924 Poulenc studied composition under Charles Koechlin. His ballet *Les Biches* was produced by Sergei Diaghilev in 1924. Settings of poems by Ronsard and *Chansons gaillardes* (1926) began a series of song cycles, chiefly on poems by Apollinaire and Paul Éluard. In 1928, at the suggestion of Wanda Landowska, he wrote *Concert champêtre* for harpsichord and orchestra. In the following year his *Aubade*, a choreographic concerto for dancer, piano, and chamber orchestra, was performed. In 1934 he gave the first of his joint recitals with the singer Pierre Bernac, with whom he later toured Europe and the United States. *Litanies à la Vierge Noire de Rocamadour* (1936), the first of his religious choral works, was followed by the Mass (1937). During World War II he wrote the cantata *Figure humaine* on poems by Éluard, inspired by the spirit of the resistance movement; it was first performed in London in 1945. In 1947 his comic opera *Les Mamelles de Tirésias*, on a farce by Apollinaire, was produced at the Paris Opéra-Comique. In 1951 he wrote *Stabat Mater*, and between 1953 and 1956 the opera *Dialogues des Carmélites* on a libretto by Georges Bernanos (La Scala, Milan, 1957). His one-act opera, *Voix humaine*, on the monodrama by Cocteau, was produced at the Opéra-Comique in 1959. Poulenc died in Paris on Jan. 30, 1963.

Predominantly lyrical and traditional in harmony, Poulenc's music revived the ironic spirit of Emmanuel Chabrier and also the elegance of the French 18th-century composers. His religious works are urbane. His songs, which number over 100, show his melodic sense and his gifts for parody and for musical prosody.

See F. Poulenc, *Entretiens avec Claude Rostand* (1954); H. Hell, *Francis Poulenc*, Eng. trans. by E. Lockspeiser (1959).

POULTRY AND POULTRY FARMING. Few agricultural enterprises are as widespread as poultry farming for the production of meat and eggs for table use, and in a number of countries, including the United States, Canada, the United Kingdom, Denmark, and Australia, the poultry industry is one of the leading branches of agriculture. Within each country egg and chicken production is by far the most important aspect of the industry.

In some areas each farmer raises a few chickens that live on table scraps and what food they can find about the house and neighbourhood; such eggs and live birds are usually consumed by the farmer and his family or sold on the local market. At the other extreme are large commercial operations, raising thousands of birds and employing the most modern of food marketing and distribution systems.

Although the greater part of the world's poultry output is based on the domestic chicken, in some countries—the United States and the United Kingdom, for example—turkeys have substantial importance. There are also locally important industries of ducks and geese. Turkeys and geese are raised only for their meat; ducks are raised sometimes for eggs, sometimes for meat. Formerly it could be said that egg and meat production mostly went together, the meat coming from hens that had completed their life as layers or from surplus male birds specially fattened. This is still true in many less developed countries and in the remoter areas of more advanced ones. After about 1950, however, especially in North America and Western Europe, egg and meat production evolved into two separate, virtually unconnected industries. The techniques there developed have been transplanted to many other countries so that nuclei of poultry production showing at least some elements of advanced systems are to be found scattered in many parts of the world.

This article discusses the different types of bird, their rearing and utilization, as follows:

I. Domestic Fowl and Their Uses

- A. Breeding
- B. Management
- C. Diseases and Parasites
- D. Marketing

II. Ducks

III. Turkeys

IV. Geese

V. Guinea Fowl

VI. Squabs

I. DOMESTIC FOWL AND THEIR USES

Breeds of the domestic fowl are descended from the jungle fowl (*Gallus gallus*, see FOWLS) of India and neighbouring countries. It is not known when this fowl was first domesticated. King Solomon's table was supplied with "fatted fowl"; but these may have been geese (I Kings 4:22, 23). The Greeks and Romans were poultry farmers and raised distinctive breeds of their own. Modern breeds are numerous, but only a few are kept pure for commerce. Most pure breeds and varieties are kept by fanciers solely for their decorative appearance and for competitive exhibition. The breeds that are of commercial value for either egg production or meat production—rarely for both—are maintained in a pure state by a few breeders only in each country. In some places they are used commercially as pure stock; but they also provide the basic genetic material for the "hybrids" that after the mid-1950s became widely used for commercial production.

The breeds known today can be divided into five classes based on their origin: English, Asiatic, American, Mediterranean, and Continental European. The breeds of Mediterranean origin are used in the makeup of a number of commercial laying hybrids, because of their superior production of eggs and their low food consumption, besides the characteristics of nonbroodiness (*i.e.*, disinclination to incubate their eggs) and small body size. (They are thus, however, not suitable for meat production.)

English and American breeds are of the heavy variety with good fleshing qualities. Some are also good egg producers. Asiatic and Continental European classes include both light and heavy breeds which are not generally economic, although many are decorative.

No brief summary can indicate the place of the various breeds in the highly diversified world poultry industry. In many undeveloped agricultural areas the fowls kept may belong to no definite breed, being the product of casual mating. In other areas poultry industries may be built on one or more well-known breeds (listed below). However, in North America and Western Europe, the bulk of the poultry industry has been built up on hybrid birds created by geneticists to meet specific needs. The basic genetic characters—such as body size, colour of egg, rate of growth, etc.—are drawn from parents belonging to different breeds and are combined as required. These methods produce large numbers of uniform offspring. In many countries, hybrids are marketed under trade names that give no indication of the breeds contributing to their makeup. An illustration of the development of these techniques is the fact that, for the production of meat poultry, male parents are bred to combine one set of characteristics and female parents to provide the others, often by different firms.

All birds within a given breed have the same shape, while varieties within a breed differ in plumage, colour, or shape of comb. The majority of the so-called fancy breeds are miniatures, *i.e.*, bantams. Although there are well over 100 breeds and varieties of fowls only a few are of economic importance; the main ones are discussed below.

Australorp.—This breed originated in Australia from Black Orpingtons imported from England. It was developed for egg production and enjoyed popularity in Australia and South Africa.

Cornish.—Originally an English breed, this was recognized as important only after it had been imported into the United States in 1887. It has excellent meat qualities and has probably contributed to the makeup of many of the proprietary broiler hybrids.

Dorking.—This was one of the oldest English breeds, but is important only for its part in the makeup of the modern Light Sussex breed.

Leghorn.—There are 12 varieties of Leghorns, which are grouped in the Mediterranean class. Of these, the single-combed White is the most important, though Blacks and Browns are favoured in some areas for egg laying. The Whites have been bred to a high level of egg production in England, Canada, Australia, and the United States, and have been used in the makeup of many of the light-type laying hybrids. Their white-shelled eggs suit North American taste, but may be at some disadvantage in Great Britain, where brown eggs are preferred.

New Hampshire.—This breed was developed in the United States from the Rhode Island Red (*see below*). It gives a good average egg yield, and has meat qualities which have been drawn on in the production of some broiler strains.

Plymouth Rock.—There are seven varieties of this American breed, but only one, the White Rock, is important. This is a good meat producer and has contributed to broiler strains. Buff and Barred Rocks are found locally.

Rhode Island Red.—This American breed is among the most popular of the heavy breeds because of its good egg production, both as a pure breed and in hybrids and first crosses. (A first cross is the offspring of one pure breed mated with another pure breed.) The Rhode Island Red is especially useful because, when mated with certain breeds, for instance the Light Sussex, it gives chicks whose sex can be distinguished by the colour of their down when one day old (females are darker).

Sussex.—Of the several varieties of this English breed the Light Sussex is the most important, because of the sex-linkage characteristic mentioned above and its good meat production. Its white skin suits the English market; the egg production of some strains is good, though food consumption is high.

Other Breeds and Varieties.—Breeds such as the Orpington and Wyandotte were once popular, especially in England, but their commercial importance declined greatly. Some of the French breeds, such as the Faverolle, which has feathered shanks, and Bresse, are good meat producers but have the disadvantage of maturing slowly. Indian Game birds, obtained by crossing English with Indian and Sumatran game fowls, were formerly used for production, but they mature late and their fertility tends to be low. The Asian breeds are the most decorative, possibly as a result of infusion of genes from wild fowl living in the same area, and are popular for competitive showing.

A. BREEDING

The majority of poultry producers in the United States and Western Europe no longer attempt to breed and rear their own stock for either meat or egg production, but buy them, generally at one day old. Chicks can travel long distances at this age without food or water, provided they are in a suitable temperature. Commercial hatcheries can produce large numbers of chicks and dispatch them to their customers by air, road, or rail in special boxes. Techniques for separating the sexes at day old have been developed giving 75–98% accuracy, so that pullets for laying can be sold alone. Chicks for meat production are usually sold straight run, or "as hatched," *i.e.*, with the sexes mixed, but can be sexed for separate selling if required.

Meat Production.—Chicken is marketed in several forms, mostly, in North America and Great Britain, as broilers and fryers. These are chickens, both male and female, of specially developed strains, reared to about nine weeks of age, and about 3½ to 4 lb. average live weight. Profit margins are so small that these chickens must grow fast and gain weight well for the feed they consume, as feed costs are at least 60% of the total costs of broiler production. Broilers are reared in one house only for the whole of their short life, in conditions as nearly ideal as knowledge permits. Very large-scale broiler production is found in the United States, the United Kingdom, and most countries of continental Europe, and there is local production in the U.S.S.R. and many other countries.

There is also poussin, capon, and roaster production. Poussins are very small chickens reared to six weeks of age for sale to some branches of the catering industry. This production is not common, for the demand for this type of bird is small.

Capons and roasters are heavier cockerels, formerly bred espe-

cially for Christmas and other festivals, kept to about 20 weeks of age and marketed at about 5 to 8 lb. weight. They may be either broilers or surplus birds of heavy breeds or heavy crosses reared especially for the table. They may spend part of their life in fields on corn stubbles after harvest. Rock Cornish hens obtained by crossing Cornish and white Plymouth Rock fowls are popular in the United States as small roasters.

Meat Production Standards.—A number of characteristics are used for selecting breeding stock for meat producers. The father of the broiler chick comes of a heavy, "meaty" male line, and its mother of a fairly meaty but not-so-heavy female line. This is because the egg production of the lighter-weight females is better than that of the very heavy females; so that the cost of each chick is reduced. Breeders select for: (1) rapid growth to marketing time; (2) low food consumption per unit of body weight; (3) good finish to the carcass at the weight at which the progeny will be marketed; (4) good, deep breast for heavy meat deposition; (5) quick growth of feathers to protect the body against scars and bruises; (6) good health and form of the bird; (7) fairly prolific female line; (8) skin colour suited to the market—usually white for the English market and yellow for North America and much of continental Europe.

Egg Production.—In the United States, the United Kingdom, most of Europe, in places in the U.S.S.R. and many other countries with commercialized agricultural industries, it is the rule to buy pullets (young hens) at day old, from hatcheries. Some hatcheries control the breeding farms that supply them with hatching eggs. The customers for the hatched chicks are either egg producers who rear their own replacement stock, sometimes under contract with larger producers; or farmers who specialize in rearing pullets, who may seek customers for their birds at various ages from about 8 weeks up to "point of lay," i.e., about 18–20 weeks.

Successful hybrids are introduced into many countries from the one where they were developed. For example, many American strains were introduced into Europe in the late 1950s and early 1960s and competed strongly with local breeds and strains. Many countries operate strict quarantine arrangements to prevent the transmission of diseases. Consequently, rather small quantities of foundation stock are usually introduced at first into a new country. Sometimes a new business is established for this purpose, or an agreement may be made with an established organization.

Egg Production Standards.—The basic characters that are considered in selecting stock are: (1) high egg production (an average of 220 eggs per year per hen housed at the start of the season should be obtainable); (2) low food consumption; (3) sexual maturity at a stage suited to the type; (4) eggs up to standard weight after not more than six weeks' production; (5) continuous production of good-quality eggs for at least 12 months after the first egg; (6) little or no broodiness; (7) health and vigour of the stock throughout their life. Many other characters also may be taken into account, e.g., the shape and strength of the eggs, their hatchability, etc.

The large breeders may test great numbers of birds in the course of selection and use electronic computers to handle the very large amounts of data assembled. Various breeding systems are used; best results are obtained by crossing two independently inbred lines to produce the commercial fowls. *See Egg; Edible Eggs.*

B. MANAGEMENT

Renewing the Flock.—Most birds lay 20% fewer eggs in their second year than in their first. But a few producers keep a flock of hens for a second year if they lay a large egg and there is a local market for large eggs.

In most countries with a commercialized poultry industry, broody hens are allowed to hatch only bantam and fancy breed eggs. All flock replacements are hatched in incubators of a cabinet or walk-in type. The walk-in incubators run by the large hatcheries will hold up to 100,000 eggs each. Hatching can be organized to take place from once or twice to five or six times a week. A rigid program of hygiene is followed both on the farms producing the hatching eggs and in the hatchery itself to ensure that only healthy chicks are sold.

Rearing Chickens.—Only very small numbers of chicks can be brooded under hens, so that most of the large numbers required are brooded artificially. Broilers can be brooded in groups of 1,000 or more, but pullets do better if reared in groups of not more than 600. Artificial brooding makes it possible to rear chicks the year round for meat and egg production.

There are several types of brooders, varying according to size design, and the kind of fuel used for heating. They range in size from those that can take 25 chicks to those accommodating several thousand, and are usually heated by fuel oil, paraffin oil (kerosene), butane, natural or liquid gas, or electricity.

For the first few days of the chicks' lives the temperature is kept at about 95° F (about 35° C) at a height of two inches above the floor of the brooder. The temperature is reduced by about 5° F each week, depending on the weather outside; it is not allowed to sink below about 70° F (about 20° C) for the first four or five weeks. The first two weeks are the critical period. By about six weeks of age the chicks should be weaned off heat. Litter should be kept dry to prevent the spread of disease.

Poultry need to have adequate trough space for food and water at all stages of their lives. Food troughs can be either circular or long. The standard circular unit, about one-foot across, is provided in a ratio of three or four per hundred birds according to age. With long troughs, half an inch to one inch per bird is allowed from day old to four weeks of age, rising to three and one half inches per bird by the time adulthood is reached and to four or five inches for layers. Automatic feeding has been introduced in large units. Drinkers also can be automatic. The number required depends on the variety of bird. No feeder or drinker should be more than about 10–12 ft. walking distance away from a bird.

The total area allotted for rearing chicks is calculated on a basis of half a square foot per bird from one to four weeks of age up to two square feet per bird for adults, with up to four square feet per bird in laying houses (*see FARM BUILDINGS: Poultry Brooders and Houses*). A number of large producers rear pullets in tier batteries which accommodate more birds. These tier houses are heated by the same fuels as are other brooders, and the pullets are already accustomed to wire floors ready for battery egg-laying accommodation.

Housing Adult Birds.—Under the battery system, housing consists of wire cages, in each of which one or more birds may be kept. Feed and water may be distributed by hand but in large units the distribution is mechanical. In fully automatic systems the cages are cleaned mechanically.

There are other systems of housing which leave the birds loose on a communal floor. Such houses may be insulated, with temperature and light control, or they may be little more than roofs with wire-netting walls; the choice of arrangement is largely according to climate. Artificial lighting is used to stimulate egg production, especially during the autumn and winter seasons (*see RURAL ELECTRIFICATION*). Birds used to be customarily kept on free range, and small flocks are still kept in this way in many countries. However, this system requires much labour and leaves the birds exposed to bad weather and predators, which puts it at a disadvantage in comparison with closely controlled systems for commercial poultry raising.

Broilers are usually raised in houses where they are free to move about the floor. However, for them, too, construction varies greatly. In England, Germany, and other continental European countries rather elaborate houses are usual; in the southern United States very simple ones serve a large industry.

Nutrition.—A newly hatched chick can survive for up to two days on the yolk ingested from the egg, but it needs to be fed as soon as possible with a mash, or with crumbs containing a source of good quality protein. Broilers, which need to grow fast all their lives, are fed on a good quality, energy-giving mash and good quality protein. Replacement pullets, once off to a good start, can be gradually weaned on to a growers' mash or pellets, the process being complete by the time they are eight weeks of age. Growers' feed has more fibre and less protein and energy-giving qualities. A hundred chicks will eat 10–20 lb. of feed in their first week and 10–20 lb. more each week for the next eight or nine

weeks. The actual amount depends on the type of chick, the energy content of the feed, and the chicks' rate of growth. A broiler chick eats about $8\frac{3}{4}$ lb. food in eight weeks to reach 4 lb. in weight. A pullet eats about 4 lb. in its first eight weeks and about 20 lb. to point of lay.

Laying birds are always fed mash or pellets in troughs. In the United Kingdom this mash contains 17% protein, and in the United States 15% protein. Its value to the fowls depends on the source of the protein. There is sufficient calcium for eggshells in the rations of most laying hens provided they are below 75% production. Hens laying more than this are fed supplementary calcium. Insoluble grit is also provided, in separate feeders. Some strains of birds reach their peak at 90% production. If the hens are to be fed a scratch feed of corn, a grain balancer diet is fed. This is made up with a high protein and low energy-giving content to counteract the effect of the added grain.

The only birds that will benefit from free-range foraging without subsidiary feeding are cockerels that are to be fattened for the table; these can survive for a few weeks on stubbles. With the development of intensive feeding systems, careful compounding of diet is required. This is done by national compounders; by local compounders serving an area of countryside (on specifications drawn up by the national mills); or by the poultry farmers themselves. This last arrangement usually pays only if the mixing equipment can be used for large quantities of stock and the grain is homegrown. Concentrates of all the essential minerals and vitamins and any extra protein required can be bought and added at predetermined levels to recommended proportions of cereals to give a balanced ration for a given class of stock. Corn (maize) and wheat are the usual grains, with milo (a grain sorghum) in the United States. Biochemists and food manufacturers conduct research into the food requirements of all types and classes of stock, so that more efficient and economical feeds can be compounded. Drugs for controlling disease often are added to commercial feeds. Antibiotic feed supplements are frequently used to increase growth rates. In the United States recommended ration formulas, continuously revised on the basis of research, are prepared by the advisory service of each state. The use of compounded feeds was at first largely confined to the sizable poultry farms of North America and Western Europe; later the small producers who formerly fed their stock from their own farm produce came to be regular buyers of compounded feeding stuffs, because they were more reliably beneficial, perhaps especially to the newer type of hybrid.

C. DISEASES AND PARASITES

All species of poultry are subject to both internal and external parasites, many of which can be controlled by appropriate drugs and disinfectants if their presence is accurately diagnosed in time; however, chemicals are no substitute for good management. External parasites—mites, lice, and fleas—can be controlled by appropriate application of nicotine sulfate, sodium fluoride, or insecticidal sprays.

Internal parasites include worms in the alimentary tract, but these are not a major problem for healthy birds. Coccidiosis (*q.v.*), a disease caused by a protozoan parasite, which affects birds while they are still growing, is potentially much more serious. It can be controlled by rearing the birds on wire floors so that they are not infected from their own or other birds' feces. Customarily, also, a coccidiostat (*i.e.*, a drug controlling the disease) is given in the feed during the early stages of the chicks' lives.

Most fungal and bacterial diseases no longer present problems to the poultry farmer. The salmonella organisms are the principal members of this group causing disease, especially in young chicks. They can be controlled by good hygiene; but, if an outbreak is suspected, effective drugs are available. Since 1935 the U.S. Department of Agriculture has conducted the National Poultry Improvement Plan to control pullorum disease (bacillary white diarrhea) and typhoid. Flocks of participating hatcheries are tested to assure that the disease will not be transmitted to chicks.

Virus diseases are the principal causes of death and loss of production. There are no effective drugs, and once an outbreak has

taken hold of a flock, control is extremely difficult. Good hygiene, including the segregation of birds of different ages, is the only means of avoiding the danger. The principal virus diseases are the fowl leukosis (leukemia) complex, including fowl paralysis (range paralysis, or neurolymphomatosis), Newcastle disease (fowl pest), and some respiratory diseases. Leukosis and fowl paralysis are extremely important in most countries with commercial poultry industries. They probably account for one-fifth of the total deaths of adult stock in Great Britain. There is no known cure or vaccination.

Newcastle disease, which is often difficult to distinguish from other respiratory diseases, must be reported in Great Britain, where a subsidized killed-virus vaccine is available for injecting into all birds throughout the country; in the United States both live-virus and killed-virus vaccines are available, and either dosed into drinking water or sprayed or dusted over the birds, thus eliminating the need to handle stock. Newcastle disease does not kill adult birds, but causes grave losses of production.

With intensive systems of poultry rearing, great care has to be taken to provide sufficient suitable ventilation lest respiratory diseases get a hold. Antibiotics and drugs can sometimes be used against them with moderate success provided that the originating cause is at least partially removed. New diseases have appeared in several countries, possibly in association with environmental changes.

Finally, there are various deficiency diseases, often with characteristic symptoms. For example, rickets, in which the bones are malformed, is caused by shortage of vitamin D; while a characteristic form of paralysis, in which the toes are curled, is caused by shortage of riboflavin.

D. MARKETING

Eggs.—Marketing systems vary as widely as do production systems. Even in countries where egg production is industrialized, a significant proportion of eggs passes direct from producer to consumer. The remainder are collected from the farms, taken to packing stations where they are candled to assess internal quality, graded, and packed in containers, often 15 or 30 dozen to a box. Retail boxes containing 6 or 12 eggs are increasingly used. Large quantities are processed and frozen or dehydrated (*see Egg: Edible Eggs*).

Before World War II a substantial international trade in eggs had grown up. Part of this was in shell eggs, of which Denmark, the Netherlands, Ireland, and Australia were among the major exporters; part was in egg products, *e.g.*, broken-out shell eggs for cold storage in cans, in which China was prominent. The United Kingdom was a major importer of shell eggs and egg products. This situation was disrupted, not only by the effects of war but also by the technological changes in the poultry industry, and by the action of a number of importing countries, *e.g.*, the United Kingdom and Germany, to protect their own egg-producing industries to the disadvantage of the exporting countries. By the 1960s, many countries were acutely embarrassed in their search for markets for a product so well suited to the small peasant farmer.

Meat.—Poultry meat also is marketed in various ways. In many countries, producers with a few cockerels or old hens sell them live to local shops or to individual consumers. Many more are collected by dealers, who dispose of them live through markets. Large producers handle their birds in specially built plants, in which they are stunned, bled, defeathered, and cooled while being moved mechanically from one part to another of the plant. They may also be eviscerated and frozen. They are then distributed: chilled, wrapped and frozen, jointed, and even cooked. There is a substantial international trade in frozen birds.

Organization of Marketing.—The scale and complexity of the poultry industry, and the large proportion of a country's production which may be controlled by a few firms, represent a break with traditional farming practice in most countries. In several countries, breeding firms can number their chick sales in terms of tens of millions a year. Individual firms may have outputs representing one-quarter or more of the total for their section of the industry; the six biggest firms in a country may account

for two-thirds or three-quarters of the national output.

Those sections of the modern poultry industry that require very heavy capital expenditure, highly skilled scientific knowledge, or experienced management, bear most of the responsibility for its success. Partly owing to the interdependence of businesses in supplying one another's raw materials, or outlets for one another's products, links have developed such that a single firm may control by contract or actual ownership two or more stages in the industry. For example, a feed manufacturer, by means of contracts with farmers on the one hand and with hatcheries on the other, may control the production of meat chickens right up to the stage where the birds are ready to kill.

Details of organization vary greatly in different parts of the world; but the "vertical integration" described above is especially widespread in North America, the United Kingdom, Germany and Italy. Not only the largest firms are involved. For example, in parts of the United States and various continental European countries in the 1960s, meat birds were raised by quite small farmers in quite small units, although these farmers were under contract to very large firms.

However, these arrangements are by no means the only ones under which poultry producers have operated. The marketing of eggs by farmers' cooperative societies has played an extremely important part in, for example, Denmark, Canada, the United States, and the United Kingdom.

But the cheapness of the individual bird still renders poultry keeping feasible for the small producer, and his few eggs can be bought even by the poorest consumer. Consequently, unorganized production—although, quite possibly, with sophisticated hybrid stock—may be found not only in countries where agriculture is still largely managed on traditional lines but also in those where it has become a network of big businesses.

II. DUCKS

Duck raising is practised on a limited scale in nearly all countries, for the most part as a small farm enterprise. The flocks once kept in England are much reduced, the demand for eggs being greatly lessened, though there is still a limited market. Khaki Campbell and Indian Runner ducks are prolific layers and can average 300 eggs a year each. (See *Ego: Edible Eggs: Duck Eggs*.)

In the United States a considerable number of commercial plants have been developed exclusively for duck-meat production, especially on the Long Island beaches. There are also local industries in the Netherlands and in England, the favourite breed in England for this purpose being the Aylesbury. This has white flesh, and can reach 8-lb. weight in eight weeks. In the United States the favourite is the Pekin duck, which is slightly smaller than the Aylesbury and is yellow fleshed. It is marketed at about nine weeks of age.

III. TURKEYS

The industry of raising turkeys for meat (see *TURKEY*) underwent technical development after World War II. Well-fleshed types, which mature at different ages, have been developed. Bronze strains reach slightly heavier weights than whites, but the latter are preferred because they are of better appearance when ready for cooking. Generally speaking, stag or tom (*i.e.*, male) turkeys reach 26-lb. weight in 26 weeks, while hen turkeys mature earlier and rarely exceed 20–22 lb.

It is now known that turkeys require a feed richer in protein at the start of their lives than do chicks. They can be reared on either wire or litter flooring, but preferably on litter, providing disease is kept under control.

Large stag (tom or gobbler) turkeys may achieve 50-lb. weight. The largest are used for catering and the smaller ones for families. Although turkey is generally eaten on festivals such as Thanksgiving and Christmas, the industry has been attempting to encourage year-round sales. In the United States smaller birds such as fryer-roasters produced from Beltsville Small Whites have gained in popularity. Besides fattening, a production of day-old "poults" also is carried on from stock developed for the purpose.

These young birds are supplied to rearers who contract with packing stations. Once the young turkeys have been encouraged to start eating, there is not much risk of substantial loss of stock, although in former times turkeys had the reputation of being extremely difficult to rear, and much folklore surrounded the feeding methods that were believed to be successful. Turkey poults are, however, very susceptible to damp, and are prone to respiratory diseases, which often affect their sinuses. The congestion can be relieved by injecting antibiotics directly into the sinuses. Poults are also susceptible to blackhead, a disease caused by a protozoan parasite, which can now be controlled by drugs.

IV. GEESSE

Goose raising is a minor farm enterprise in practically all countries, but in Germany, Austria, some eastern European countries, parts of France, and locally elsewhere there is important commercial goose production. The two outstanding meat breeds are the Toulouse, predominantly gray in colour, and the Embden, which is white. Geese do not appear to have attracted the attention of geneticists on the same scale as the meat chicken and the turkey, and no change in the goose industry comparable to that in the others has occurred or seems to be in prospect. In some commercial plants, geese are fattened by a special process resulting in a considerable enlargement of their livers, which are sold as a delicacy. See *Goose*.

V. GUINEA FOWL

Guinea fowl (*g.v.*) are raised as a sideline on a few farms in many countries. In Italy there is a fairly extensive industry. They are reared in yards with open-fronted shelters. In England they are usually marketed at 16–18 weeks of age and in the United States at about 10–12 weeks of age. The market weight is usually about 2½–3½ lb. but their food conversion is poor. They are used to some extent as a substitute for game.

VI. SQUABS

Pigeons are raised not only as messengers and for sport (see *PIGEON*; *PIGEON FLYING*) but also for the meat of their squabs (nestlings). Squab production is carried on locally, but is rare in most countries with established poultry industries. A pair of pigeons can rear six pairs of squabs a year, and they are marketed at three to four weeks of age. Traditionally, the adult birds have often been left to pick up what food they could find in the neighbourhood where pigeon raising for meat is carried on: a source of annoyance believed to be not unknown at the present day. Racing and exhibition pigeons have much greater attention paid to their diet.

POUND, SIR (ALFRED) DUDLEY (PICKMAN) ROGERS (1877–1943), British naval officer, first sea lord and admiral of the fleet during World War II, was born on Aug. 2.

1877, on the Isle of Wight, the son of an English father and an American mother. He entered the navy in 1891. As a lieutenant he specialized as a torpedo officer, and in 1913 was appointed as an instructor at the new naval staff college. Having been promoted captain in 1914, he served as assistant to Admiral Lord Fisher. At the battle of Jutland he commanded H.M.S. "Colossus." During the last years of the war he reorganized the operations division at the admiralty into the plans division, of which he was director from 1922 to 1925. He then served two years in the Mediterranean under Admiral Sir Roger Keyes, returning to the admiralty as assistant chief of naval staff with the rank of rear admiral (1927-29). From 1929 to 1931 he commanded a battle cruiser squadron and from 1932 to 1935 was second sea lord. He was commander in chief of the Mediterranean fleet (1936-39) at the time of the Spanish civil war. In May 1939 he was recalled to become first sea lord and chief of naval staff, which office he held until three weeks before his death on Oct. 21, 1943. In July 1939 he was promoted admiral of the fleet.

As first sea lord Pound shared the responsibility with the first lord, Winston Churchill, of mobilizing the fleet and conducting the naval war at a critical period. Unlike the air ministry and the war office, the admiralty was an operational centre, so that Pound was personally involved in such events as the hunt for the "Graf Spee," the Norwegian campaign, the fall of France and the early U-boat campaign. The most successful collaboration between the planning staff at the admiralty and the commander in chief at sea was the sinking of the "Bismarck." Pound combined exceptional administrative ability and capacity for work with an imperturbable temperament.

POUND, EZRA LOOMIS (1885-), U.S. poet, critic and one of the most influential single agents in the development of 20th century English writing, was born in Hailey, Ida., Oct. 30, 1885. His family traditions were those of the northwestern frontier, where a man thrived by discerning the most direct procedure and pursuing it boldly. By the time he had settled in Europe (1907) after an education in romance philology at the University of Pennsylvania and Hamilton college, he had developed his unique conviction that poetry is a craft demanding active intelligence, and begun his lifelong labour of educating and assisting his contemporaries. As foreign editor of *Poetry* (Chicago) he brought to its pages Robert Frost, W. B. Yeats and the first published work of T. S. Eliot. He forced Wyndham Lewis' *Tarr* and James Joyce's *Portrait of the Artist as a Young Man* (1916) and *Ulysses* (1922) into print, founded the Imagist movement and in 1922, by a brilliant feat of editing, extracted Eliot's *Waste Land* from a sprawling manuscript twice its published length.

His major poems are *Homage to Sextus Propertius* (1917), *Hugh Selwyn Mauberley* (1920), and *The Cantos*, a long work in progress, dating from the early 1920s, that undertakes to assemble, sharpen and order the traditions and signposts of fructive intellectual history. His translations include the Anglo-Saxon *Seafarer* (1912), the Chinese *Cathay* (1915) and *Classic Anthology* (1954), and the Confucian books (1947-50). His *Letters* were published in 1950, and a selection of his *Literary Essays* in 1954.

From 1946 to 1958 he was confined in St. Elizabeth's hospital in Washington after being ruled mentally unfit to answer indictments for treason growing out of broadcasts he gave on the Italian radio, 1940-45. Following his release from St. Elizabeth's, Pound returned to Italy.

In June-July 1965 Pound made an appearance at the Festival of

POUND, ROSCOE (1870-1964), U.S. jurist, one of the most influential figures in U.S. legal education, and a leading exponent of the reform of judicial administration, was born in Lincoln, Neb., Oct. 27, 1870. He studied at the University of Nebraska, where he received a B.A. degree in botany in 1888. In 1889 he received his M.A. degree in the same subject. He studied law at Harvard for one year (1889-90), passed the Nebraska bar without his law degree, and until 1907 practised law in that state. He taught at the University of Nebraska (1890-1903) and was commissioner on uniform state laws for Nebraska (1904-07). During that time he had earned a Ph.D. (1897) in botany from the university and directed the botanical survey of the state (1892-1903), during which he discovered the rare lichen *Roscopoundia* which was named for him. After teaching at Northwestern University and the University of Chicago, Pound went to Harvard as professor of law, and in 1916 he became dean of the Law School. Resigning as dean in 1936, he received a "roving professorship" and taught a variety of subjects until his retirement in 1947. After his retirement he was active in numerous legal, editorial, and educational positions. He spent a few years in Formosa reorganizing the Nationalist Chinese government's judicial system.

Pound's activities in bar association work led to close cooperation between law teachers and the organized bar. Many fields of the law, including jurisprudence, Roman law, equity, and criminal law, were enriched by his writings and teaching. He directed the Cleveland Survey of Criminal Justice in 1922 and was a leader in the cause of efficient court administration. He died on July 1, 1964, in Cambridge, Mass.

Pound wrote nearly 1,000 pieces, including 250 books and major papers, and 250 opinions as commissioner of appeals of the Supreme Court of Nebraska (1901-03). He also did research and writing early in his career on botanical geography. Among his books are *The Spirit of the Common Law* (1921); *Criminal Justice in America* (1930); *Organization of Courts* (1940); *The Task of the Law* (1944); *New Paths of the Law* (1950); *Justice According to Law* (1951); *The Lawyer from Antiquity to Modern Times* (1953); and *Jurisprudence* (1959). His many awards included the William Volker Distinguished Service Award (1953).

POUND. The basic unit of weight in English-speaking countries is the avoirdupois pound. By agreement between Australia, Canada, New Zealand, the Republic of South Africa, the United Kingdom, and the United States, the pound is defined for international purposes at 0.45359237 kg. But in each country the standard pound as determined by the national laboratory differs slightly from the international pound.

The earliest weight in the English system was the Saxon pound, subsequently known as the tower pound from the old mint pound kept in the Tower of London. It weighed 5,400 gr. and this weight of silver was coined into 240 pence or 20 shillings, hence pound in the sense of an English money of account (see **MONETARY UNIT**). The pound troy, probably introduced from France, was in use by 1415. In 1527 an act of Henry VIII substituted a pound troy of 5,760 gr. (the "pounde Troye which exceedeth the pounde Tower in weight iii quarters of the oz.") as the legal standard for gold and silver, abolishing the tower pound. In use at the same time were two merchant's pounds of 6,750 and 7,200 gr. for goods sold by weight, *avoir de pois*. The official avoirdupois pound was in use in the reign of Edward I but Henry VIII changed it from 15 oz. troy to 16 oz. avoirdupois. The overlap in the avoirdupois and merchant's pounds led Elizabeth I to discard the latter and establish Henry VIII's avoirdupois pound as the only legal avoirdupois pound at 7,000 gr. divided into 16 oz. (437.5 gr. to the ounce).

The standard troy pound and the standard yard, in the custody

of the clerk of the House of Commons since 1758, were destroyed in 1834 at the burning of the Houses of Parliament. In 1841 the report of a commission on the restoration of the standards led to the substitution of the pound avoirdupois of 7,000 gr. for the pound troy as the standard. A new standard pound avoirdupois was made in 1844, by comparison with authenticated copies of the original standard, and was legalized in 1855. The standard avoirdupois pound is made of platinum, in the form of a cylinder nearly 1.35 in. (3.43 cm.) high and 1.15 in. (2.92 cm.) in diameter, and is marked "P.S. 1844. 1 lb.," P.S. meaning parliamentary standard. It is preserved at the Standards Office, in the custody of the Board of Trade. The term "troy pound" was abolished in 1878 but the decimal multiples and submultiples of the ounce troy continue in use for gold, silver, and medicines.

See the *Reports of the Standards Commission*, 6 pt. (1868-73).

POUSSIN, GASPARD: see DUGHET, GASPARD.

POUSSIN, NICOLAS (1593/94-1665), the greatest and most characteristic French painter of the 17th century, the leading exponent of pictorial classicism of that period and one of the greatest masters of all time, was born near Les Andelys, Normandy. At about the age of 17 he moved to Paris, where he stayed for the next 12 years, working under various Mannerist artists and studying in the royal collections of painting, sculpture and engraving. At the court of the queen mother he met his first important patron, the Italian poet G. Marino, who commissioned a series of drawings illustrating Ovid's *Metamorphoses*. They are at once crude and Mannerist in style and not very promising.

In 1624 Poussin reached Rome, where Marino introduced him to Marcello Sacchetti, through whom he met Francesco Cardinal Barberini. His style during this period is not easy to define as he was experimenting in various directions at once; but one important influence was that of the Bolognese classical artist, Domenichino. The culminating work of this phase was a large altarpiece for St. Peter's representing the "Martyrdom of St. Erasmus" (1629; Vatican gallery). However, it was a comparative failure and Poussin never again tried to compete with the Italian masters of the Baroque on their own ground. Thereafter he painted only for private patrons and confined his work to a format rarely more than five feet in length. From 1629 to about 1633 Poussin took his themes from classical mythology and from Torquato Tasso, and his style became romantic and poetical under the influence of the Venetians, especially Titian; examples are "The Arcadian Shepherds" (1629; Chatsworth, Derbyshire), "Rinaldo and Armida" (c. 1629; Dulwich) and "Cephalus and Aurora" (c. 1630; National gallery, London).

In the mid-1630s he began deliberately to turn toward Raphael and antiquity for his inspiration and to evolve the purely classical idiom which he retained to the end of his life. He also included religious themes once more, beginning with stories which offered a good pageant (e.g., "The Worship of the Golden Calf," c. 1636; National gallery), but going on to choose incidents of deeper moral significance in which human reactions to a given situation constitute the main interest. The most important work which exemplifies this phase is the series of "Seven Sacraments" painted for Cassiano del Pozzo, secretary to Francesco Barberini, of which five are now in the duke of Rutland's collection; in connection with another, "The Gathering of Manna" (1639; Louvre, Paris), Poussin wrote that it should be possible to "read" the emotions of all the various figures in the composition.

In 1640 Poussin was summoned to Paris by the king and Cardinal Richelieu, and among his commissions was the decoration of the long gallery of the Louvre. However, disillusionment set in, the local artists intrigued against him and he returned to Rome in 1642. The most valuable result of his visit to his native country had been the friendships which he formed with his French patrons, notably Fréart de Chantelou, whose interest in Stoic and Epicurean philosophy appealed strongly to Poussin. Both his religious and secular paintings of the 1640s and 1650s are concerned with moments of crisis or difficult moral choice, and Poussin's heroes are always those who reject vice and the pleasures of the senses in favour of virtue and the dictates of reason; e.g., Coriolanus,

Scipio, Phocion, Diogenes. His style was consciously calculated to express such a mood of austere rectitude. Thus in the "Testament of Eudamidas" (1644-48; Copenhagen) there are only five figures, all painted in dull or harsh colours against the severest

"THE HOLY FAMILY" BY NICOLAS POUSSIN. IN THE NATIONAL GALLERY OF IRELAND

possible background. Even in his landscapes, a form which Poussin first took up about 1645 and which he used for the stories of Diogenes and Phocion, the disorder of nature is reduced to the order of geometry, and trees and shrubs are made to approach the condition of architecture. The second series of "Seven Sacraments," executed for Chantelou (1644-48; earl of Ellesmere's collection), has a solemnity which is relatively lacking in the more picturesque first series. In each case the composition is conceived very carefully, not only on the surface but also in depth, recalling the methods of Raphael and reflecting Poussin's own practice at this time of supplementing his preparatory drawings with a three-dimensional model made of wax figures set in a boxlike stage.

Poussin believed in reason as the guiding principle of artistic creation and he was an artist who, in Sir Joshua Reynolds' phrase, was "naturalized in antiquity," yet his figures are never merely cold or lifeless. Though in pose they may resemble figures used by Raphael or in ancient Roman sculpture, they have a strange and unmistakable vitality of their own. Even in his late period, when all movement, including gesture and facial expression, had been reduced to a minimum, his forms are instinct with life. The devotion he has inspired in so many later French artists, among them David and Ingres, Cézanne and Picasso, bears eloquent testimony to this. Poussin died in Rome on Nov. 19, 1665.

POVERTY may be defined as an insufficiency of the material necessities of life. This is not a very exact definition because the necessities of one society may be luxuries in another and unknown in a third. The idea of insufficiency is likewise difficult to fix with precision. Some writers distinguish between poverty as the normal condition of the poorest stratum of a population, and indigence as a crisis caused by the interruption of income.

Another way of looking at the matter is to distinguish types of poverty. Collective poverty, for instance, is a more or less permanent insufficiency of the material means of life for an entire population. Most of the population in such regions as India and central Africa falls into this category. Lower income groups in the prosperous countries of the West also suffer from collective poverty, as found, for example, among migrant farm workers and urban slum dwellers in the United States.

Cyclical poverty is the widespread but temporary deprivation

that occurs because of a failure of crops in an agricultural economy, or a breakdown of trade in a commercial economy, or overproduction in an industrial economy. In former times, the term cyclical poverty implied the periodic recurrence of famine. In modern times cyclical poverty usually denotes associated mass unemployment.

Individual poverty is a condition of want that results from individual misfortune or incapacity. In every society the widows and orphans, the victims of disaster, the criminals and the outcasts, the lame, the halt, the blind, the mentally abnormal and deficient, the drunks and drug addicts, the sick and the aged have special problems of support. In industrially advanced countries it has become customary for the state to provide varying degrees of relief for each of these situations, but such measures are often inadequate to support a normal style of life.

Some mention should also be made here of "ideal poverty," which is a condition of want maintained as an end in itself. Christianity and Buddhism both give a large place to the conception of poverty as a virtue, and both provide for vows of poverty to be taken by those entering the religious life. There is also a long tradition of poverty as a secular virtue, going back at least as far as Lycurgus' constitution for ancient Sparta.

The range of want is bounded at one end by literal starvation, a common phenomenon throughout the world in earlier times and one that still occurs with appalling frequency in underdeveloped regions and in the wake of war. At the other extreme of the range, poverty may be merely a failure to achieve the expected level of living in a particular society at a particular time. Since the level of living of technically advanced countries rises steadily, there are many inconsistencies of time and place. The 20th-century English pauper eats more and better food than the propertied yeoman of two centuries ago. A temporarily unemployed factory worker in the United States usually enjoys more comforts than a fully employed labourer in Brazil.

Regardless of variations in the phenomenon of poverty, there are two important things which may be said about it.

First, the penalties of poverty are always severe. Compared with their contemporaries, the poor appear always to have shorter lives, more illness, more physical and mental defects, more personal crises, less education, less opportunity for improvement, and less protection from hazards.

Second, it appears plainly that the economic progress of advanced societies in the past few centuries has tended to mitigate poverty by abolishing famine and raising the minimum level of living which society will tolerate (see STANDARD OF LIVING). Although many doubts have been expressed as to the ultimate value of this economic progress, it is absurd to deny its existence. There is hardly any useful commodity whose per capita consumption has not increased in a spectacular way in the last century. In the more industrialized countries of the world, attention has shifted almost completely from the age-old problem of finding enough food for the population to the new problem of furnishing every family with automobiles and refrigerators and even in many of the most backward and overcrowded agricultural regions, the increase of productivity and the improvement of transportation have made it technically possible to protect everyone from hunger.

Despite these favourable omens, the majority of the world's families in mid-20th century were still desperately poor compared with the average family of North America or Europe. The first result of a secure food supply is a violent increase in population; consequently, there is sometimes a decline rather than an advance of living standards in the presence of increasing social wealth. (See POPULATION: Theories and Policies.) This is what seems to have happened in Europe in the early part of the 19th century and it was still occurring in various parts of the world in the second half of the 20th century where waves of population growth were still gathering momentum. Although the semistarvation which was normal throughout past history is now comparatively rare, it is estimated that half of the human race still subsists predominantly on coarse grains, and that at least seven-tenths do not have a nutritionally adequate diet. The average daily ration of a Chinese could be obtained by an American automobile worker in exchange

for about four minutes of work.

Collective Poverty.—There are two situations which may account for collective poverty—a scarcity of resources or an unequal distribution of resources.

The relative abundance of economic products depends upon the level of technical development in an area and the density of its population. A primitive economic system, without much use of nonhuman energy, may nevertheless be able to provide a fairly high level of living if the density of population is low and there is an abundance of arable land and other natural resources. This is still the case in many of the Pacific islands. With a moderately advanced technology, differences of population density become critical. Although the French controlled much the same technology as the English in the 18th century, the much greater population density of France produced living conditions which struck Arthur Young and other English observers as degraded. Similarly, despite the steady advancement of Indian agriculture and industry in the past three centuries, the acceleration of population growth in the same period—presumably due to the reduction of famine—seemed to have lowered the level of living appreciably. The existing evidence suggests that the average Hindu of today does not consume as much as his forebears under the Mogul Empire.

In the ancient world, where the growth of population was almost universally restricted, the level of living appears to have been distinctly higher than in medieval or early modern Europe.

In advanced economies, the relationship between density of population and level of living disappears, because the availability of land no longer sets the limits for total production. In the United States the net value added by agriculture fell below 10% of the national income after World War II, although the value of agricultural production was more than 20 times as great as it had been before the Civil War. During the same century, the proportion of the labour force engaged in agriculture declined from two-thirds to less than one-sixth.

In the 1960s, North America, with less than 10% of the world's population, had almost 40% of the world's income, while Asia with more than 50% of the world's population had approximately 20% of the world's income. Per capita income in the United States was more than \$2,000 while it was less than \$100 in China, India, some parts of southeast Asia, and central Africa.

The meaning of Chinese or Indian poverty in actual experience is that the mass of population in these countries must spend most of their energy earning food. Even so, they are unable to obtain a balanced diet. In order to obtain the minimum number of calories required for survival, most of their food intake must be in the form of cereals or rice. Regardless of the type of agriculture the calorie output per man-hour of labour is greater in the production of grains than in the production of other foodstuffs. Even in the most prosperous countries there are regions and classes which do not share in the general prosperity. In the United States, where per capita consumption far exceeds that of the rest of the world, in the early 1960s there were 1,800,000 families with incomes under \$1,000 and another 3,250,000 whose incomes did not exceed \$2,000. Much of the poverty that existed was concentrated in certain economically depressed areas, and in 1961 the U.S. Congress passed the John F. Kennedy administration's "aid to depressed areas" bill. In 1964, following Pres. Lyndon B. Johnson's State of the Union message declaring "unconditional war on poverty in America," Congress adopted the Economic Opportunity Act and, in 1965, the Appalachian Regional Development Act. The programs set up to promote economic opportunity included (1) a Job Corps, similar to the Civilian Conservation Corps of the 1930s, in which young men and women aged 16–21 could receive vocational training, education, and work experience; (2) special local work-training programs (the Neighborhood Youth Corps) in which young persons aged 16–21 could receive on-the-job and related training; (3) assistance to institutions of higher education to help provide students from low-income families with part-time work; assistance to local communities and organizations for a wide variety of community programs to improve education, employment opportunities, and living conditions; (5) pilot projects to train heads of families receiving public assistance aid to equip

them to get jobs and become at least partially independent, where feasible; and (6) a Domestic Peace Corps (called Volunteers in Service to America, or VISTA) through which young men and women could serve as teachers and social workers among American Indians, the mentally ill, migratory workers, and other disadvantaged groups. The program also provided for assistance to migratory workers; loans to stimulate and strengthen small business; and loans to low-income rural families.

The Appalachian Regional Development Act provided for special assistance for an 11-state area stretching along the Appalachian Mountain chain from the inland regions of the Middle Atlantic states southward (Pennsylvania to Alabama). To assist this poorest section in the nation, an economic development program included a road-building program to provide jobs as well as improved transportation and communication facilities, water and flood control programs, programs to improve livestock, lumbering, and coalmining operations, and vocational training and health facilities construction. Together, these programs were regarded as a commitment to eliminate pockets of poverty in the midst of prosperity, primarily through education and job training and retraining.

Available evidence indicates that economic progress is normally accompanied by equalization of earnings; that the most unequal distributions are found in the poorest countries and the least unequal distributions in the richest countries regardless of their differing social and economic arrangements.

It is not only because of the widespread prevalence of misery that the contrast between rich and poor is more striking in undeveloped areas. The actual inequality appears to be greater. Because of the close and probably inherent relationship between economic progress and equalization of income, the remedy for collective poverty is always essentially the same. In every case, some way must be found of raising the total income of the poverty-stricken population. In other words, per capita consumption of goods and services must be raised. This in turn can be accomplished only by an increase of output per man-hour worked, since in the long run a population cannot consume more than it produces.

The consequences of collective poverty are most strikingly evident in an examination of population statistics. The life expectation at birth around 1960 was over 65 in North America, most of western Europe, and Australia. It stood between 55 and 65 for countries of intermediate prosperity such as Yugoslavia, Portugal, and Argentina; between 45 and 55 for poor countries, such as Bolivia, India, and Morocco; and less than 45 in a few countries such as Burma, Guatemala, and Brazil. Infant mortality showed an even wider range, from more than 150 deaths per 1,000 live births in the first year of life in the least favoured areas to about 25 in the richest areas. On the other hand, these differentials seem to be declining rapidly.

The relationship between collective poverty and the birth rate is much more complex and cannot be fully treated here. As noted above, the first technical advances in a formerly undeveloped area are likely to be followed by sharp increases of population. The two reasons for this are the decline of infant mortality and the elimination of famine. This is what happened to the European population in the 17th century and it produced a tenfold increase in about ten generations.

Subsequently, with increasing industrial advancement, more and more of the population is drawn into nonagricultural employments and into the cities, whose habits of life tend toward smaller families. Eventually, as happened in France around 1900 and in the United States about 1930, the birth rate may fall below the level which is necessary for the long-run maintenance of a stable population. However, with continued prosperity and the decentralization of the urban population, there is a tendency for a new cycle of population growth on a more moderate scale to appear. There is no assurance, of course, that economic progress will not be interrupted at some point in this sequence. It can be argued that the commercial development of India and Indonesia by European colonists was initially responsible for the inflation of population by improving the material conditions of life, but that as the colonial system became stabilized, the further progress which would have checked the growth of population was prevented.

The problem of increasing productivity in overcrowded areas has recently received a good deal of attention, especially in connection with programs of technical assistance to former colonial areas. Increasing the productivity of an "underdeveloped" country is always difficult but probably never impossible. Several conditions must be met. First, capital must be provided from an outside source. Underdeveloped areas produce barely enough to keep their populations alive and are unable to provide new capital equipment out of surplus production. Second, improvements to be undertaken must be adapted to the economic circumstances and resources of the area. In a sparsely populated region with no scarcity of land, such as the irrigable deserts of the Near East, the principal need is for hydroelectric or atomic energy to stimulate manufacturing. In moderately settled areas, with primitive agricultural techniques, the most promising solution to collective poverty seems to be the improvement of agricultural productivity, since there is no other way of releasing materials and manpower for industrial production. In an area of dense agricultural population with traditions of intensive cultivation, the improvement of transportation may claim first attention.

Technical innovations cannot be successfully made without taking account of the total pattern into which the new elements must be fitted. The meanings attached to a tractor or a lathe are not the same in all cultural settings. The attitudes which contribute to industrial efficiency in Detroit cannot readily be mobilized in Rangoon. On the other hand, the fundamental motives for technological improvement exist almost everywhere—as demands for higher living standards.

In general, the penetration of Western technology into the remote corners of the world does seem to be ameliorating their poverty, although slowly and unsteadily. Recent years have seen a remarkable expansion in the total supply of mechanical energy, which more than doubled from 1930 to 1960. Urban dwellers in the second half of the 20th century were generally far better fed, clothed, and housed than the average of their preindustrial ancestors, and there was every reason to think that this improvement would be continuous if not interrupted by the nuclear destruction of civilization. For most of the world's people, however, the economy of abundance was still out of reach and would remain so until the rising trend of production clearly outstripped the rising trend of reproduction.

Cyclical Poverty.—In the preindustrial world, economic crises were accompanied by high prices. Prices rose periodically because of scarcities of food, which brought widespread misery. Since the Industrial Revolution, the typical crisis has been caused by overproduction and accompanied by low prices. The sign of crisis and the characteristic type of cyclical poverty in economically advanced countries is mass unemployment.

There are some exceptions to the foregoing generalization, of course. Crises of overproduction were not entirely unknown in the commercial towns of an earlier era. Food scarcities occurred in the 20th century as a result of war or enemy occupation. The Netherlands, for example, suffered an authentic famine in the winter of 1944–45.

Famine was extremely common in the preindustrial world. The last major famine in western Europe due entirely to natural causes was that of 1709, but hunger has appeared at many times and places since then. Even in the United States, which has not known a general famine, there has never been a year in which some areas, such as the mountain counties of Kentucky, did not experience widespread hunger.

The business cycle in the modern sense, with accompanying mass unemployment, developed gradually in the 19th century. While the severity of successive crises varied, their consequences broadened as national economies became more dependent upon each other. There was also an irregular tendency for crises to last longer and longer. The Great Depression which began about 1929 lasted for the better part of a decade in most of the countries involved.

In 1935 the number of unemployed in the United States approached 20,000,000, and about one-third of the population was receiving public relief or assistance. The impact of the crisis was

equally severe in western and central Europe where it was further complicated by the political unrest which eventually led to World War II. Unemployment decreased very gradually from the high point of the early 1930s, and it was not until after the outbreak of war in 1939 that the surplus manpower was absorbed. Although the business cycle has been closely studied and the entire pattern of events is well understood, economists are not unanimous as to the causes. The remedies are of two kinds. First, through control of production or through the manipulation of market mechanisms, the state may intervene to interrupt the deflationary spiral of falling prices and decreasing employment before it acquires momentum. Second, the victims of unemployment may be partially protected by social security (*q.v.*) or governmental subsidies in cash or kind, or by employment on public works. As a matter of fact, all of these devices were finally adopted by the governments of all of the countries involved in the Great Depression, although with many variations of detail. In Great Britain the principal reliance was upon direct assistance, commonly known as the "dole." In the United States, after some experimentation, the federal government established the huge public enterprise known as the Works Progress Administration. During the same decade, a great deal of experimentation was carried on with devices for controlling the cycle itself. In England, France, Italy, and the Scandinavian countries, government participation in heavy industry was increased. In the United States, Canada, Germany, and some other countries, the central supply of bank credit began to be vigilantly supervised and controlled.

Whether these devices have effectively restricted the business cycle must for some time remain uncertain. Conditions in the period after World War II did not permit a clear-cut test. A high rate of productive activity throughout the world was associated with heavy military expenditures and a number of unusual circumstances that facilitated economic cooperation among the nations.

Even in the absence of widespread mass unemployment, unemployment continued to present serious local problems here and there in the world, being sporadically severe in some sections of every economy. The alleviation of unemployment by insurance benefits or other forms of relief had become a standard practice in civilized countries. Such aid is only sufficient to cushion the unemployed against homelessness and starvation. It cannot prevent other kinds of family hardship, including the loss of savings, the thwarting of plans, and the experience of insecurity.

Individual Poverty.—The term "individual poverty" may be used to denote the inability or failure of an individual or a family to obtain the necessary income to sustain the minimum customary level of living at a given time and place. There is, of course, a numerical correlation between the incidence of individual poverty and of collective or cyclical poverty. In a poor country or in a bad year, the risks of indigence for marginal wage earners will be very much greater than in prosperous countries and good years. Nevertheless, the phenomenon of individual poverty is quite distinct. It occurs whenever regular earnings are interrupted in such a way that the individual or family can no longer purchase food, clothing, housing, and fuel, or when the earnings of a handicapped or underprivileged worker are so low in proportion to his obligations that he cannot sustain himself without outside aid.

The earliest students of this subject took some comfort to their consciences by blaming the undeserving poor for their own plight. Thus, in his *Inquiries Concerning the Poor*, the Rev. John McFarlan of Edinburgh wrote in 1782 that "in tracing the causes of poverty, I have endeavoured to show that the greatest number of those who are now objects of charity are either such as have reduced themselves to this situation by sloth or vice, or such as, by a very moderate degree of industry and frugality, might have prevented indigence." Somewhat later it became a scholarly game to estimate the exact proportions of blameless and blameworthy paupers. Late in the 19th century, Amos G. Warner concluded that 25% of the poor in the United States owed their condition to laziness, shiftlessness, and insobriety, while the remaining three-quarters were victims of misfortune. British studies of the same period estimated about half of the poor to be innocent and the other half responsible for their own misfortunes. The first scien-

tifically respectable study of the causes of individual poverty was made by the tireless Charles Booth, who analyzed 4,076 cases of indigence in London. For 62%, the principal cause of poverty was ill-paid or irregular employment; 23% of his sample had been reduced to misery by large families or illness. The remaining 15% were said to be drunken, thriftless, or lazy. In subsequent British investigations by B. Seebohm Rowntree and by Sir Arthur Lyon Bowley and A. R. Burnett-Hurst, the attempt to find a single cause of poverty was abandoned. Among low-paid factory workers, illness or temporary unemployment was likely to bring bitter hardship for those families with many children. The same contingencies threatened only moderate hardship for single wage earners or small families. The death of the principal wage earner usually meant the impoverishment of a family with small children.

Poverty could also be explained by the varying number of dependents whom the worker had to support during his lifetime taken in relation to his varying earning power from youth to old age. Rowntree, whose three social surveys of the English town of York (in 1900, 1936, and 1950) were the most detailed empirical investigations made in this field, described a career pattern for the industrial worker. It is characterized by two periods of sufficiency above the poverty line, in youth and in middle age, when the worker enjoys full earnings but has no dependent children; and by three episodes of poverty, as a dependent child, as an overburdened young father, and as a dependent old man. Something like this individual career pattern can probably be traced in every social stratum, although it is a little difficult to establish with precision in the highly dynamic economies of the 20th century in which the conditions of the worker's childhood are not likely to remain stable until his old age.

A good deal is known about the style of life of families living at a level below their previous minimum. Available cash tends to be used for the purchase of food, and there is a continuous depletion of savings, family capital, and credit. Carle C. Zimmerman studied the living conditions of Cuban families who had incomes of less than one dollar per day. Practically all of their resources were devoted to food. In less favourable climates, the problem of finding housing at the level of living where all income is needed for food is likely to provoke community action before absolute indigence is achieved. The history of such measures may be briefly summarized:

In the preindustrial era the care of paupers was everywhere a local responsibility, and everywhere reluctantly discharged. The role of the central government, as illustrated in the famous Poor Law (*q.v.*) of Elizabeth I (1601) and the edicts of Colbert concerning the treatment of vagabonds, was limited to seeing that local responsibilities were more or less carried out. Less extreme cases were generally handled by private action and some elements of aid to the poor fell into the sphere of the church. In the industrial era, with the coming of large-scale urbanization, this traditional local responsibility collapsed. For a while nothing took its place except sporadic repression by the police. As Anatole France remarked, "The law, in its majestic equality, forbade the rich and poor alike to sleep under bridges." Beginning with the social insurance program in Germany between 1878 and 1891, the next 75 years saw the enactment, at uneven rates and in various fashions, of a more or less complete program of welfare measures in every industrialized country, designed to provide minimum subsistence to the victims of each category of poverty. In the United States the enactment of such measures was one of the central themes of the New Deal. It included unemployment insurance, pensions for the aged, aid to widows and dependent children, and special provisions for the blind and the handicapped. The main outlines of this system were embodied in the Social Security Act of 1935 and its many later amendments, and in Great Britain earlier legislation along these lines was strongly supplemented by the enactment subsequent to World War II of most of the features of the "cradle to grave" protection proposed by the 1942 Beveridge report. (See also SOCIAL SECURITY; SOCIAL SERVICE; SOCIAL WELFARE.)

Individual poverty in the prosperous countries may be said to be well on the way to solution. The abolition of beggary, of spec-

tacular misery, and even of the traditional roles of the widow and the orphan is a cultural revolution whose exact implications are difficult to grasp.

However, many residual problems remain. Pensions and welfare payments tend to be meagre when first established and to become more so with time as they lag behind changes in the price level. In the United States especially, the high cost of medical services creates a special category of hardship. The piecemeal nature of most welfare programs and the prevailing sentiment that public welfare benefits should be kept at a low level means in practice that although starvation has been abolished, misery is often perpetuated.

POWDER METALLURGY, the fabrication of useful items from a metal powder or a mixture of powders, thus differing from most metallurgical techniques, which initially involve the solidification of a molten metal. Fabrication by powder metallurgy techniques is usually employed for one of two reasons:

1. Such techniques may be the only known or least expensive means of producing certain metals, alloys or mixtures of two or more metals having desirable physical or mechanical properties. This is the case in producing metals having very high melting points, such as tungsten; in making alloys of two metals or materials that cannot normally be mixed together, such as copper and graphite; and, finally, in producing porous parts which can allow a liquid or gas to permeate their pores.

2. Powder metallurgy may be the cheapest method of manufacture, as is often the case where a large number of identical small parts, such as gears for calculating machines, are required. Powder-metallurgy techniques can be used to form such parts directly to shape, with little or no finishing or machining required. Also, scrap losses are minimized, and raw-material inventory for production consists of only a few grades of metal powder. These three factors contribute to the economic advantages of powder-metallurgy techniques.

BONDING OF METAL POWDER

In order to bond powder particles into a mass which is solid enough to withstand the stresses encountered in service, the powder must be heated, or sintered. This may require from a few minutes to two or three hours for completion. There are two distinctly different types of sintering encountered in powder metallurgy. One is described as solid state sintering: the sintering temperature is such that there is no molten metal present during the major portion of the sintering period. One of the constituents of the powder being sintered may melt initially when the powder is first heated, but if this molten metal alloys with the solid particles present and thus disappears during the course of sintering, the process is considered to take place with essentially no liquid present.

A second type of sintering, known as liquid phase sintering, is carried out with a mixture of low- and high-melting-point metal powders. The sintering temperature is above the melting point of the lower melting component so that molten metal is present during the entire sintering period. The molten metal wets the remaining solid particles and rapidly flows around them and into the spaces between them if enough of the liquid metal is present, in some cases dissolving a portion of the solid powders. When the powder is cooled from the sintering temperature, the molten metal solidifies and bonds the solid particles together. By contrast, in

solid state sintering, the solid particles of metal must be allowed to bond themselves together through the rather slow motion of individual metal atoms within the solid.

Solid state sintering is analogous to the coalescence of small drops of water to form a single large drop. A finely divided material, either solid or liquid, will tend to reduce its exposed surface area as much as possible. In the case of a metal, the strength of the particles resists this tendency unless the temperature is high enough to allow the atoms of the metal to move about to some extent within the particles. The lowest temperature at which this motion takes place is called the recrystallization temperature of the metal.

Table I gives the recrystallization temperatures and the melting

TABLE I.—Recrystallization Temperatures and Melting Points

Metal	Recrystallization temperature, °C	Melting point, °C
Tin	20	232
Aluminum	150	660
Silver	200	961
Copper	200	1,083
Beryllium		1,280
Iron	450	1,533
Titanium	600	1,668
Zirconium	750	1,852
Molybdenum	900	2,610
Tantalum	1,050	2,996
Tungsten	1,200	3,410

points of some metals commonly used in the powder-metallurgy industry. Sintering of these metals must take place above the recrystallization temperature but below the melting point if the part being sintered is to retain its shape.

The time required for sintering to take place in the solid state depends on the condition of the powder, the size of the particles and the sintering temperature. The closer the packing of the powder particles, the smaller the particle size and the higher the temperature, the shorter the time required for sintering. To keep the sintering time within reasonable limits, the powder is generally compacted under high pressures to bring the particles as close together as possible. The average particle size ranges from about 0.004 to 0.00001 in. in diameter, and the powder contains both large and small particles in order to have as many points of contact between particles as possible. The temperature of sintering is kept as high as possible above the recrystallization temperature as is consistent with retaining the desired shape of the part being made.

During liquid phase sintering, the proportion of liquid to solid metal must not get too high, or the part will lose its shape, or distort badly. The amount of molten metal present should not exceed about 30% of the total volume of liquid and solid together. The time required for sintering in this instance generally depends on the condition and size of the solid particles and upon the temperature, just as in solid state sintering. However, the greater the amount of liquid metal present during sintering, the shorter will be the sintering time.

One other variety of sintering is actually intermediate between the two types described above. If a metal powder is partially sintered in the solid state, it will contain interconnected holes or pores between the solid metal particles. If the partially sintered metal is placed in contact with a molten metal that will wet the sintered powder but not alloy with it, then the molten metal will infiltrate the sintered powder and, if enough liquid is present, fill up the pores.

In all sintering processes the dimensions of the mass of powder change during sintering. This change is almost invariably a shrinkage. The amount of the shrinkage depends on the composition of the powder, the amount of compression to which the powder has been subjected before sintering and the time and temperature of sintering. Shrinkages vary from 1 or 2% up to about 25%. This shrinkage must be allowed for in the design of parts which are to be made directly to shape.

MANUFACTURE OF METAL POWDERS

In general, metal in powdered form is a premium product, since energy must be expended to obtain a metal in a finely divided

condition. Also, powders for powder metallurgy must often meet certain specifications as to particle size, shape and other properties. To meet these, careful precautions may have to be taken during manufacture of the powder. There are two classes of methods used to manufacture metal powders: mechanical and chemical.

Mechanical methods are applied to either solid or liquid metals. The most widely used method for solids is milling by power-driven hammers (hammer milling) or balls in a rotating container (ball milling). If the metal is brittle, it will easily break into many small, equiaxed particles. Milling times may run from one or two hours to 100 hours or more, with the longer times resulting in very finely divided powder. This type of particle can be used in powder-metallurgy products. If the metal is ductile, however, and can be readily deformed, it will form small, flat flakes when pounded. This type of particle is not well adapted to fabrication of items by powder-metallurgy techniques but finds use as pigment for inks and paints. Solid metals can also be cut or machined to produce fine chips. Liquid metals can be subjected to various processes that break up the metal into droplets, atomizations, which are allowed to solidify in air or water. In most of these methods a stream of liquid metal is broken up by an air blast or a stream of water and the air or water also cools, or freezes, the metal droplets. Another method consists of having a stream of molten metal fall onto a rotating wheel which is simultaneously cooled by air or water. These processes are applicable to any metal or alloy that can conveniently be melted. Metals with melting points up to and including that of iron or steel can be produced in powder form by these techniques.

One advantage of mechanical methods of powder production is that alloy powders containing two or more constituents can be produced. Such alloys as brass (copper-zinc), bronze (copper-tin) and steel (iron-carbon) can be produced in powder form in this way. This is not generally true of the chemical methods of powder production. The greatest disadvantage of milling methods is that these are restricted to brittle metals or alloys, and most useful metals, like copper and iron, as well as their alloys, are ductile. This problem can sometimes be avoided by intentionally embrittling a normally ductile material, pulverizing this while it is in the brittle condition and then treating the powder to restore its ductility if ductility of the powder is required. Certain magnetic iron-nickel alloy powders are made in this fashion.

Chemical methods of producing metal powders are adaptable to a large number of metals. In reduction, the most widely used method, a compound of the metal (generally an oxide, although sulfides and chlorides are also employed) is reduced by a chemical agent, either a gas, liquid or solid, which breaks down the compound into particles of the desired metal and some by-product which must be removed or separated from the metal itself. If the original metal compound is a solid, the size of the particles of the resultant metal depends largely on the condition of the solid compound; a finely divided compound will yield small metal particles. Most solid metal compounds, like oxides, are brittle and can be milled to a fine particle size, so with these the reduction method can produce a finely divided metal powder.

Where the by-product of the reduction of a metal compound and a chemical agent is a gas, its removal is simple and requires only some form of vacuum pump or a continuous flow of an inert or reducing gas to sweep the by-product away. An example is the reduction of copper oxide with hydrogen gas at 350° C. (662° F.) to form copper metal and steam. The steam is easily removed by continually passing fresh hydrogen over the solid copper oxide. The by-product may, however, be a solid or a liquid which solidifies on cooling from the reduction temperature, as in the case of the reduction of titanium tetrachloride with magnesium at 900° C. (1,652° F.). The by-product formed along with the titanium metal is molten magnesium chloride, which solidifies around and between the titanium particles. The magnesium chloride must be dissolved away from the titanium with dilute acid or removed by melting and distillation in a vacuum.

Another widely used chemical method is the electrolysis of a liquid solution which contains the desired metal. Many metal

compounds may be dissolved in water at room temperature or in a molten metal compound at elevated temperatures. An electric current is passed through the solution, and the metal is deposited on the cathode. This process is similar to electroplating, but the conditions of current and temperature are adjusted to produce a porous, flaky or brittle deposit of metal. This coating is scraped off or broken up to obtain the powder. If the powder is required to be ductile, it is generally heated in an inert or other protective atmosphere to soften the metal. Nickel, copper and iron powders are often made by this process from aqueous solutions. Titanium and zirconium powders are made by electrolysis of fused chlorides.

A few miscellaneous chemical methods are used to produce minor amounts of metal powders. Some metals, like copper, are readily obtained as water solutions of their compounds. If clean scrap iron or steel is placed in these solutions, copper metal will be precipitated while iron dissolves in the solution. Since copper is more valuable than steel, this process is economically sound for copper production. Iron and nickel form gaseous compounds with carbon monoxide at elevated temperatures and pressure. These compounds are called carbonyls, and they may be broken down into metal particles and carbon monoxide again at low pressures. This technique allows the formation of spherical particles of iron or nickel, which are useful in certain specialized applications in the electronics industry. Stainless steel which has been slowly cooled from a high temperature is attacked rapidly at local areas throughout the material by dilute acidic copper solutions in water. This local attack causes the stainless steel to literally fall apart into individual particles, which can be quite small if the material has been properly treated. This last case is an exception to the general rule that alloy powders cannot be made by chemical methods.

TABLE II.—Metal Powder Manufacturing Processes

Metal	Processes
Tin	Atomization
Aluminum	Atomization
Silver	Atomization, electrolysis, precipitation
Copper	Reduction, atomization, precipitation, electrolysis
Brass	Atomization
Bronze	Atomization
Beryllium	Reduction, electrolysis
Iron	Reduction, electrolysis
Steel	Atomization
Titanium	Reduction
Molybdenum	Reduction
Tantalum	Electrolysis
Tungsten	Reduction

Table II is a list of some metals used in powder metallurgy, along with the processes which can be used to produce each.

PROCESSES AND PRODUCTS

The processes used in powder metallurgy can be divided into three general classes, depending on the types of metal used in each: those involving metals of relatively low melting point which are ductile, such as silver, copper and iron; those processes involving the so-called refractory metals of high melting point which are usually brittle, such as tungsten, molybdenum and titanium; and the processes for the production of materials known as cemented carbide, which contain tungsten carbide.

Ductile Metals.—Parts made from ductile metal powders generally are produced directly to the shape in which they will be utilized. Most of these parts which are produced by powder metallurgy consist of an alloy of two or more metals, such as copper and tin, or a mixture of two or more metals that do not alloy and that cannot normally be mixed together, such as copper and tungsten. If an alloy part is the final product, it is often made by starting with the separate constituents and allowing alloying to take place during the sintering operation, rather than starting with alloy powder. This practice is usually carried out with parts made from copper alloys, while iron-alloy parts are more often made by starting with alloy powder.

The production starts with the mixing or blending together of the required constituent powders along with a solid lubricant, which is very similar to a soap, such as zinc stearate; this lubricant allows the powder particles to flow easily and also is neces-

sary to reduce friction when the powder mixture is pressed to shape. The powder at this point has a density of about 50% to 60% of the density of a similar mass of solid, nonporous metal of the same composition.

A pressing, or briquetting, operation forms the metal powder to the desired shape at room temperature. A die of strong, hard material, generally a high-quality steel, and a punch, or plunger, are used. This method of forming parts has several limitations that must be borne in mind in the design of parts to be made from ductile metals by powder metallurgy. The die must have straight sides and cannot be undercut, since metal powder, even though it is blended with a lubricant, will not flow readily into an undercut portion of the die cavity that is not directly subjected to pressure from the punch. In addition, the powder tends to adhere to the inside walls of the die cavity. This effect is called die-wall friction and acts to decrease the pressure which is available to compact the powder. Despite lubricants blended in with the powder, die-wall friction prohibits the compaction of parts whose height is more than about three times their width, so that tall, narrow shapes are not easily made by pressing. Die-wall friction also causes wear of the die; the lifetime of a die is of the order of 150,000 pressings even when the surface of the die cavity is made as hard and wear resistant as possible.

BRIQUETTING PRESS SHOWING (LEFT) PART EJECTED FROM THE DIE AND (RIGHT) METAL POWDER FROM WHICH PARTS ARE MADE

The pressures used to compact ductile metal powders range from about 10 to 50 tons per square inch, depending on the shape of the part and the type of metal used. After pressing, the part is removed from the die, and the pressure used must have been sufficient to give the compacted powder enough strength to withstand this removal and subsequent handling. If only a few parts are being made on an experimental basis, simple hand-operated hydraulic presses are used. If many thousands of parts are to be made, automatic presses, either mechanical or hydraulic, are necessary; the former have maximum capacities of about 100 tons total force and can produce parts at rates up to 100 per minute, while the hydraulic presses are capable of exerting up to 5,000 tons total force at a rate of one to five pressings per minute. The tonnage capacities of such presses limit the size of parts that can be made to about two inches square in mechanical presses or about eight inches square in hydraulic presses. One type of automatic mechanical press known as the rotary press compacts several small batches of powder simultaneously and is capable of a maximum output rate of several thousand parts per minute. Automatic presses measure the correct amount of powder into the die cavity, compact the powder, eject this compacted powder and then repeat their cycle. Either the total amount of compaction of the powder or the total force exerted on the powder may be controlled, depending on the type of press. Some presses have a double action that exerts pressure on the powder in the die from both top and bottom to obtain more uniform compaction.

During pressing, the metal powder is compacted by a ratio of almost 2 to 1, so that the compacted powder is about 60% to 80% as dense as a similar mass of solid metal. Only ductile metals can be subjected to a compaction of this magnitude. Brittle powders usually have a high strength that prevents such a considerable compression at practically attainable pressures, and even if they could be compressed by the application of a high enough pressure, the particles of a brittle material would fracture and not interlock or flow around each other as do the particles of a ductile metal powder. This last feature is particularly important, since it means that the interlocked particles of a compacted

ductile metal powder will have appreciable strength after pressing. The powder after pressing is called a green compact and should have a strength of at least a few hundred pounds per square inch to allow normal handling. The exterior surface of the green compact after it has been ejected from the die will have almost exactly the same shape and size as the cavity of the die in which it was formed. To develop strength to withstand the stresses encountered in service, however, it must be sintered to bond the individual particles together.

Sintering of green compacts of ductile metal powders generally takes place with no liquid phase present, since this method of sintering results in the least distortion of the shape of the green compacts. Many iron-powder parts, however, are sintered in contact with molten brass or copper, so that the liquid metal infiltrates the partially sintered iron structure. The furnaces used for sintering ductile metals show as much variation in size and type as do presses for compaction. Sintering furnaces have one characteristic in common: they must protect the heated metal powder being sintered from contact with the air if a clean, oxide-free part is desired. Gaseous furnace atmospheres commonly used for this purpose are carbon monoxide-carbon dioxide mixtures with varying amounts of nitrogen, pure hydrogen, and hydrogen-nitrogen mixtures. The carbon monoxide-carbon dioxide mixtures are made from the partial combustion of coke or illuminating gas; hydrogen is made by electrolyzing water into its constituents and is readily available commercially; and hydrogen-nitrogen mixtures are obtained by the dissociation of ammonia gas. The sintering atmosphere is usually enclosed in a muffle which is heated externally by burners or electric-resistance elements. Electric heating is more generally used because it is clean and easy to control. The temperatures used to sinter ductile metal compacts range from about 900° C. (1,625° F.) to about 1,300° C. (2,372° F.).

The smaller furnaces used for sintering may be only a few feet long and of the pusher type in which an operator places green compacts in trays and pushes these slowly through the furnace from one end to the other. This type will sinter only a few hundred parts per hour. Large furnaces are employed where many parts must be sintered, and may be of the pusher type with automatic and mechanized operation, the roller-hearth type with rollers along the bottom of the muffle over which trays of parts are passed, or the belt-conveyer type which has an endless heat-resistant alloy belt passing continually through the furnace. This latter type of furnace can sinter thousands of parts per hour. (See FURNACE, METALLURGICAL.)

The strength and toughness of a sintered compact of a ductile metal powder will be somewhat less than those of a cast material of the same composition due to porosity inherent in the powder-metallurgy part. Infiltration of a partially sintered part, however, increases its strength. Also, parts made from some types of steel powder can be heat-treated after sintering to develop higher strengths than would be obtained from as-sintered material. In general the good compressive strength and the lower tensile strength and toughness of pressed and sintered parts must be considered for projected applications.

Ductile metal compacts experience a shrinkage of about 1% to 5% in their dimensions during sintering. When this is properly allowed for in the design of dies, sintered parts can be produced which will have their dimensions equal to any specified size within a tolerance of from 0.3% to 1%. Many parts produced to such tolerances can be used as is, with no further treatment necessary. This dimensional tolerance may not meet all design requirements, however, so that some postsintering operation is necessary. The most common procedure is to make parts slightly oversized as regards the exterior dimensions and then compress the part slightly in a split or sectional die to bring it to the correct size. This is known as coining, and no metal is removed from the part in this operation. Interior dimensions, some exterior contours, and such features as an internally threaded hole which cannot be pressed to shape require machining operations on the sintered part. Sintered parts may also receive treatments other than coining or machining. Parts designed for use as bearings are usually im-

pregnated with lubricating oil or a solid antifriction material by means of a vacuum treatment. The oil in the pores of the bearing serves as a reservoir for lubrication during the lifetime of the bearing. Steel parts which require high strength may be reheated and quenched in oil or water to develop this strength. Parts may also be electroplated to provide a more corrosion-resistant or attractive surface.

A few types of powder-metallurgy products made from ductile metals do not follow the exact cycle of pressing and sintering which has been described. Metal-powder filters are one example of such parts. These filters are made from powder particles of equiaxed or spherical shape and uniform size so that the openings between the particles will all be of the same size. The powder is not pressed, since pressing would distort the particles. Instead the powder is poured into suitable forms of graphite or ceramic and heated while still confined in these forms. The sintering of the particles is allowed to take place to develop reasonable strength in the filter, but not to the extent where the pores between the particles are closed up due to shrinkage.

Alloy powders, such as bronze or stainless steel for corrosion-resistant purposes, are generally used in the manufacture of metal-powder filters.

The pressing operation may also be replaced by other compacting procedures. Ductile metal powder can be fed between a pair of rotating rolls which compact the powder into a wide, continuous sheet. Or metal powder can be extruded through a shaped, wear-resistant alloy nozzle called an extrusion die. This process is much like that of pressing paste through a tube, except that higher pressures are required. Extrusion is particularly successful in fabricating parts from aluminum powders. (See also DIE CASTING.)

Table III is a list of some of the items made from ductile metal powders. Some of these have unique compositions or physical

Refractory Metals.—The refractory metals can be considered as those with melting points above about 1,600° C. (2,912° F.), with the exception of beryllium, which melts at 1,280° C. (2,336° F.). These metals, unlike metals of lower melting points, are generally obtainable from their compounds only as powders. They are usually utilized in the pure form or with only small amounts of other elements as alloying additions. A few parts are made directly to shape by the pressing and sintering of powders of the refractory metals, just as in the case of ductile metal powders. This is particularly true with beryllium and titanium. Chiefly, however, powder metallurgy is used to produce a bar or ingot of the refractory metal, which is then further processed by mechanical working to make wire, rod, tubing or sheet.

Since most refractory metals form powder particles which are either too brittle or too hard to be compacted like the ductile metals, they can be compacted at room temperature only with a binder to hold the particles together. Examples are niobium, tantalum, molybdenum and tungsten. Production starts with the blending of the metal powder with from ½% to 2% of a binder, such as paraffin wax, dissolved in a volatile solvent. The solvent is evaporated by gentle heating to leave a coating of binder on each powder particle. The powder is then compressed at pressures of up to 50 tons per square inch, in a die with a rectangular cavity about 1 in. in cross section by 12 or 18 in. in length. The pressing is usually carried out in hydraulic presses controlled by hand. The rate of production is low, but the refractory-metal products are not made in as large quantities as are parts made by powder metallurgy from the ductile metals. The binders used do not have much strength so that the compacted powder is quite fragile and must be handled carefully to prevent breakage.

The green compact is presintered in a protective atmosphere at about 1,000° C. (1,832° F.) to volatilize the binder and to give the compact enough strength to withstand further sintering. The second sintering must be carried out at high temperatures that would be difficult to obtain in conventional furnaces (see Table I). Heating of the ingots to accomplish sintering is carried out by passing a heavy electric current through the metal. Heat is generated directly within the ingot because of the resistance it offers to the current flow. (See FURNACE, ELECTRIC.) The amount of the current is carefully controlled to bring the temperature of the ingot close to its melting point to carry out sintering in the shortest possible time. Distortion of the ingots is pronounced under these conditions but is not important, since the ingot is mechanically worked by hot forging or other processes after sintering.

The atmosphere used for sintering of the refractory metals must not only prevent oxidation of the metal but also must not react detrimentally with the metal itself. For molybdenum and tungsten purified hydrogen gas makes a satisfactory atmosphere. Since niobium and tantalum are embrittled by heating in a hydrogen atmosphere, they are sintered in vacuum.

Molybdenum and tungsten ingots are brittle, although strong, after sintering, in contrast to niobium and tantalum. Some amount of ductility can be produced in the former by proper mechanical working of the ingots; this working also closes up the pores remaining in the ingot after sintering, to make a completely dense material. The sintered ingots must first be forged hot, then forged or rolled at successively lower and lower temperatures until deformation, such as cold-rolling into sheet or drawing into wire, is possible at room temperature.

To make ingots or certain shapes of refractory metals from powders, the processes of pressing and sintering can also be combined into a single operation known as hot-pressing. This is actually compaction of the metal above its recrystallization temperature. Extrusion is a more satisfactory process to achieve compaction than is pressing in a die because of the problem of finding a die material that can withstand the high temperature encountered in hot-pressing. In extrusion, on the other hand, the process is so rapid that the extrusion die does not become too hot during the process except at the surface immediately in contact with the hot metal powder. Hot extrusion has been applied chiefly to beryllium, zirconium and titanium. Since these metals would oxidize if exposed to air when hot, the powders are placed

TABLE III.—Items Made From Ductile Metal Powders

Description	Composition	Uses
Small structural parts, such as gears, cams, retainers	Iron, brass, bronze, iron infiltrated with copper, aluminum	Machine parts where strength is not extremely important
Small structural parts	Steel	High strength machine parts
Porous bearings	Bronze, copper-graphite, lead-bronze	Bearings or bushings (often impregnated with lubricating oil)
Electric conductors	Copper-tungsten, silver-molybdenum, copper-graphite	Switch contacts, current collectors in rotating machinery
Friction linings	Copper-graphite, silica-lead	High-friction material for heavy-duty clutches and brakes
Filters	Bronze, iron, stainless steel, nickel alloys	Rigid filters, corrosion-resistant filters
Heavy metal	Tungsten-nickel	High-density material for weights and radiation shielding

properties that can be attained only through use of powder-metallurgy techniques. Others could also be made by more conventional processes but are sometimes more economically produced by powder metallurgy when a large number of parts, of the order of 10,000 or more, is required.

in a thin-walled steel container which is evacuated by means of vacuum pumps. The container and powder are then heated, and the hot assembly is extruded in presses of up to 1,000 tons capacity. The steel container is removed after extrusion by machining. The result of extrusion is a rod or tube with a diameter of up to two or three inches, which is almost completely dense. A rod can be further mechanically worked by rolling or other processes, while tubes are used for applications requiring piping which has to withstand corrosive or other conditions for which these metals are suited. In this connection, it should be noted that beryllium and zirconium are both particularly useful in the production of nuclear energy, since these metals have a very low neutron absorption, and parts made from them can be used in the interior construction of nuclear reactors.

Hot-pressing with a die is most feasible with refractory metal powders if the powder is placed in the die and heated by passing a current through the powder itself. If the rate of heating of the powder is high enough, the die will not become hot throughout but only at the surface in contact with the powder. This technique requires that the powder be insulated electrically from the die wall by some type of high-resistance lining so that the die will not short-circuit the heating current around the powder.

Ingots of the refractory metals can also be made from relatively coarse powders of these metals by the process of arc melting. In this process, the powder is fed through a vertical hollow tube into an electric arc which is struck between the powder and a water-cooled ingot mold. The heat of the arc actually sinters the powder as it approaches the end of the tube so that the arc is burning from the relatively rigid sintered powder at the bottom of the tube. The heat of the arc melts the powder, but not the water-cooled mold, so that molten metal drips into the mold to form a small pool of molten metal just beneath the arc. Arc melting is carried out in a vacuum to prevent oxidation of the metal and also to eliminate impurities in the metal which can be removed as gas or vapour.

Completely dense ingots weighing over 100 lb. can be produced by arc melting; these are generally brittle as made and must be hot-forged and mechanically worked like a pressed and sintered ingot. Arc melting has been successfully applied to all refractory metals.

Some of the refractory metals, notably titanium, molybdenum and tungsten, are used as alloying elements in the manufacture of certain grades of steel. The metals are alloyed with molten iron in about a 50-50 proportion to form a brittle material which is then crushed to a coarse powder for addition to molten steel.

TABLE IV.—Refractory Metals

Metal	Use
Beryllium	Construction of nuclear reactors, windows for X-ray tubes, lightweight panels for space vehicles
Zirconium	Construction of nuclear reactors, corrosion-resistant parts
Titanium	Lightweight aircraft parts, corrosion-resistant parts
Molybdenum	Vacuum-tube components, electrical resistors, electrical contacts
Tantalum	Highly corrosion-resistant parts, vacuum-tube components, electrical capacitors
Tungsten	Vacuum-tube filaments and parts, electrical contacts, glass-to-metal seals, rocket nozzles, nose cones and ion engines

Table IV lists some of the uses of relatively pure refractory metals made by powder metallurgy.

Cemented Carbides.—The so-called cemented-carbide materials made by powder metallurgy contain, as their principal constituent, powder of the compound of tungsten and carbon known as tungsten carbide. This compound is formed by heating tungsten powder and carbon powder together to 1,500° C. (2,732° F.) in a hydrogen atmosphere for from one to two hours. The powders are held in graphite crucibles and heated in electric furnaces. Other refractory metals, notably titanium and tantalum, also form similar compounds, and these are often used along with tungsten carbide powder. The carbides have extremely high melt-

ing points and are very hard. The principal use of cemented carbides is as metal-cutting tools and as parts which must resist wear or abrasion.

The melting point of carbides is so high that pure tungsten carbide powder cannot be satisfactorily sintered. The carbide particles must be bonded or cemented together with another metal, and cobalt is generally used for this purpose in amounts ranging from 3% to 25%. The manufacture of cemented-carbide materials starts with the blending of carbide powders and cobalt powder. The blended powders are mixed with a binder, as in the case of the refractory metals, and pressed to shape in a die and punch set. A presintering treatment at about 900° C. (1,652° F.) evaporates the binder and results in a material which has about the strength and consistency of chalk. The material in this condition can now be shaped by machining or grinding to provide the shape necessary in the finished part. The machining operation must be carried out at this point in the manufacture because the final product is so hard as to defy most cutting or grinding operations except those using the hardest of abrasives.

After shaping the presintered compact to size, this is sintered at a temperature of from 1,450° C. to 1,550° C. (2,642° F. to 2,822° F.). During this sintering process the cobalt melts so that molten cobalt metal completely surrounds the carbide particles. Shrinkages of up to 25% in the dimensions of the compact take place during sintering, and this shrinkage must be carefully allowed for in the shaping of the presintered compact.

The furnaces used for sintering cemented carbides are fairly small. Many utilize a ceramic muffle tube and an electric-resistance heater made either from one of the refractory metals, such as molybdenum, or from graphite. Some furnaces consist of a graphite muffle tube surrounded by a water-cooled coil of copper tubing, with a high-frequency electric current passing through the tubing (3,000-100,000 cycles per second). This arrangement is known as an induction-heating furnace, since the high-frequency current in the coil induces an electric current in the graphite tube within the coil. The induced current, in turn, heats up the graphite to a high temperature. In both types of furnace, purified hydrogen gas is generally used as the furnace atmosphere to protect the carbide and the cobalt metals from oxidation and also to protect the heater of an electric-resistance furnace or the graphite of an induction-heating furnace. To accomplish this, the entire furnace, heater and muffle alike is surrounded by an enclosure which contains the furnace atmosphere. Electric-resistance furnaces used for sintering cemented carbides are of the pusher type, while induction-heating furnaces are usually batch type which must be loaded with presintered compacts, heated to the sintering temperature, cooled, emptied of their charge and then reloaded. The heating and cooling rate of an induction-heating furnace are high enough so that this procedure is feasible. (See also ELECTRIC FURNACES.)

The sintered carbide material may be utilized as is or subjected to further operations. In the manufacture of cutting tools for high-speed metal-cutting machines, such as lathes, milling machines or drill presses, the cemented carbide is needed only for the tip of the cutting tool. A steel shank, which is a rod or rectangular piece of tough steel, is used to hold a small piece of the sintered carbide material. This piece may typically be only a fraction of an inch in thickness and half an inch square. Small pieces of cemented carbide of this type are fastened to the steel shank by brazing or soldering with copper or silver alloys. This technique can be used to fasten cemented-carbide tips to lathe cutting tools, drills, saw blades and almost any other type of cutting tool. The advantage of cemented carbide over tool steel as a cutting tool stems from its ability to cut while red hot.

If the cemented carbide is to be used as a wear-resistant material, it may be inserted in a hole made in a heavier piece of steel. The dimensions of the carbide and the hole should be such that the carbide can be pressed into the hole under pressure. Another method of getting a good fit is to cool the carbide to below room temperature, while the steel is heated to cause expansion. If the dimensions of the carbide and the hole are correct, the carbide can easily be inserted in the hole in the warm steel and

when the whole assembly reaches room temperature, the steel will have contracted around the cemented carbide to grip it tightly.

A few types of small cemented-carbide parts are made by hot-pressing in dies, as in the case of refractory metals. This process offers some advantage in rapidly producing parts of somewhat lower quality than those made by pressing and sintering.

Carbide powders can also be used to provide hard, wear-resistant coatings on large areas of a softer metal without going through the pressing and sintering cycle. For this purpose, carbide powder and cobalt powder are forced into a hollow nickel or iron tube about one-quarter inch or larger in diameter. Twelve-inch lengths of this carbide-filled tubing can be used as arc-welding electrodes to provide a hard facing of carbide particles bonded with a cobalt-nickel-iron alloy on any electrically conducting surface. The process consists of striking an electric arc between the electrode and the surface to be plated, just as in arc welding. The heavy electric current in the arc (50–200 amp.) causes melting of the end of the tube, the cobalt and the surface layer of the work being plated. Tungsten carbide and molten metal drop from the end of the electrode to the surface of the work and solidify there to produce a material much like a cemented carbide. In this fashion, a tough base metal may be coated with an extremely wear-resistant coating about one-sixteenth to one-eighth inch thick.

In another version of this process, a hot mixture of tungsten carbide and cobalt powders is projected forcibly onto a base-metal surface by a gas explosion to produce very thin wear-resistant coatings on the base metal.

Since the end of World War II, much effort has been devoted to the development of heat-resistant materials which can operate under stress at high temperatures, as, for example, in gas turbines or jet engines. These materials have been made experimentally from powdered compounds of refractory metals with carbon, boron and silicon. These elements form carbides, borides and silicides, respectively, with most of the refractory metals. Powder particles of these compounds can be bonded together with a metal, as in the manufacture of cemented carbides. The major shortcoming of such materials is their poor resistance to mechanical shock.

The same may be said of metal-ceramic combinations made from ceramic powders which are bonded with a metal (see METALLURGY: *Cermets*). But ceramic parts of silicon carbide and aluminum oxide are produced by pressing and sintering on an industrial scale for unique application.

Among the metal carbides that have been developed for high-temperature operation are those of titanium and chromium, with nickel or a nickel-base alloy as the binder. These were developed primarily for use in jet-engine components, with high resistance to oxidation at temperatures from 870° to 1,200° C. (about 1,600° to 2,200° F.). These carbides also are sometimes referred to as "cermets." In addition to jet-engine components they have been used in high-speed tools, dies and other high-temperature applications. Chromium carbides with nickel, nickel-chromium or nickel-cobalt as binder are resistant to oxidation and corrosion at temperatures up to 980° C. (about 1,800° F.). Commercial applications include dies, punches, valve components, etc. Carbides of molybdenum, vanadium and hafnium with metal binders of cobalt, nickel, iron or chromium have been developed for specialized uses, as in rocket nozzles.

POWDER RIVER, the name of two streams in the western part of the U.S., one heading in Wyoming and the other in Oregon. Powder river in Wyoming drains the east and south slopes of the Bighorn mountains through Crazy Woman and Clear creeks and a flat central plains area through its north, middle, and south fork tributaries. Near Kaycee, Wyo., the river flows east 18 mi.

and then bends abruptly north to the Wyoming-Montana border, where it curves eastward and then northward to join the Yellowstone near Terry, Mont. Little Powder river, an east side tributary, heads in Wyoming near Gillette and flows due north to the main stem near Broadus, Mont.

Powder river in northeastern Oregon is bordered on the west by the Blue mountains, on the north by the Wallowa mountains and on the south by sagebrush-covered hills. The river flows generally southeast and empties into Snake river near Robinette, Ore. (G. V. Sk.)

POWELL, CECIL FRANK (1903–), British physicist, who was awarded the 1950 Nobel Prize for Physics "for his development of the photographic method in the study of nuclear processes and for his discoveries concerning mesons," was born at Tonbridge, Kent, Dec. 5, 1903. After studying natural science at Sidney Sussex College, Cambridge, he worked for two years as a research student in the Cavendish Laboratory. In 1928 he was appointed research assistant to A. M. Tyndall, director of the Wills Physical Laboratory at the University of Bristol; there he remained as lecturer, reader and, after 1948, as Melville Wills professor of physics. His experiments led to many fundamental discoveries. The most important of these was the development of a photographic method of observing the tracks of elementary particles. The method was subsequently applied to the study of the particles occurring in the primary cosmic rays which come from outer space. This was done by exposing plates coated with a special emulsion on high mountains and in special balloons made of a thin plastic material. One consequence of this work was the discovery in 1947 of new forms of matter, the heavy mesons. Powell was elected a fellow of the Royal Society in 1949, and was given its Royal Medal in 1961. In collaboration with G. P. S. Occhialini he wrote *Nuclear Physics in Photographs* (1947), and with P. H. Fowler and D. H. Perkins, *Study of Elementary Particles by the Photographic Method* (1959). (W. J. Br.)

POWELL, JOHN WESLEY (1834–1902), U.S. ethnologist and geologist, the founder of the United States Bureau of American Ethnology, is remembered both for his pioneer classification of American Indian languages and for his surveys of the Rocky Mountain region. He was born in Mount Morris, N.Y., on March 24, 1834, and educated at Wheaton (Ill.) and Oberlin (O.) colleges. After serving in the Union Army throughout the Civil War, he began his professional career in geology with his appointment, in 1865, as professor of geology and curator of the museum at Illinois Wesleyan University, Bloomington, and afterward at Illinois Normal College, Normal. In 1867 Powell began a series of expeditions to the Rocky Mountains and the canyons of the Green and Colorado rivers during which, in 1869, he made a daring boat trip of three months through the Grand Canyon. For the Smithsonian Institution, in which he founded and directed the Bureau of American Ethnology, he also made ethnological studies that resulted in the first definitive analysis of North American Indian languages. His able work led to the establishment of the United States Geographical and Geological Survey of the Rocky Mountain Region, with which he was occupied from 1870 to 1879. This survey was incorporated with the United States Geological and Geographical Survey in 1879, the year in which Powell became director of the Bureau of American Ethnology. In 1881 he was appointed director also of the geological survey, a post he occupied until 1894. He died in Haven, Me., on Sept. 23, 1902.

Powell's works in linguistics included *Introduction to the Study of American Indian Languages* (1880); and the classic "Indian Linguistic Families of North America," Bureau of American Ethnology, *Seventh Annual Report* (1891). His main publications in geology were *Exploration of the Colorado River of the West and Its Tributaries* (1875); *Report of the Geology of the Eastern Portion of the Uinta Mountains* (1876); *Report on the Lands of the Arid Regions of the United States* (1878); and *Canyons of the Colorado* (1895).

See F. S. Dellenbaugh, *A Canyon Voyage* (1962); M. T. Place, *John Wesley Powell: Canyon's Conqueror* (1963).

POWELL, VAVASOR (1617–1670), a Welsh-speaking leader of the Puritans in Wales in the 17th century, was born at

Cnwclas, in the parish of Heyop, Radnorshire. While a schoolmaster at Clun, Shropshire, he was converted to Puritanism by Walter Cradock. After two years as vicar of Dartford, Kent, in 1646 he received a certificate from a parliamentary committee as a preacher at large in Wales, where by 1654 he had become known as the "metropolitan of the itinerants." Later Nonconformity in mid-Wales owed much to his labours. The political opinions which he developed under the influence of millenarianism led him to oppose Oliver Cromwell's Protectorate, against which he framed a remonstrance with 322 signatures, *A Word for God* (1655). He was no insurgent, but he was suspect. In 1661 he was excepted from the coronation pardon and for most of his remaining years he was in prison, either in Southsea Castle, Hampshire, or in the Fleet Prison, London, where he died on Oct. 27, 1670. He issued nine works during his lifetime; others, including an autobiographical piece, appeared posthumously.

POWER, LIONEL (?-1445), English composer and music theorist, whose association with Christ Church Priory, Canterbury, began in 1423. During the last four years of his life he received a yearly allowance of livery, presumably for musical assistance either as composer or as composer and organist. In previous years he could have served in a less exalted capacity than the *armigeri* (esquires) among whom his name appears, and may well have acted as instructor in music. He died in Canterbury on June 5, 1445. As a composer, he was closely in touch with musical developments in France, and made use of the chanson style (melody in the uppermost voice part) in such works as the *Missa alma redemptoris mater* and the motet "Mater ora filium." The *Missa rex seculorum* may also be his, though it is ascribed to John Dunstable in some sources. Just over 30 of Power's compositions have survived; some were published in the series *Denkmäler der Tonkunst in Österreich* and in the Plainsong and Mediaeval Music Society's edition of *The Old Hall Manuscript* (1930-38). (D. W. St.)

POWER. The word "power," as used by the engineer, indicates energy under human control and available for doing mechanical work. The principal sources of power are the muscular energy of men and animals; the kinetic energy of the winds and of streams; the potential energy of water at high levels, of the tides and of waves; the heat of the earth and of the sun; and heat derived from the combustion of fuels. Of these sources of power the winds, waves and solar heat suffer the disadvantage of being essentially intermittent and therefore requiring some method of storage of power if the demand for power is continuous. From the point of view of the size and cost of the power plant, when large amounts of power are required, windmills, wave motors and solar engines are not adaptable to large-scale power generation; tidal power, while it may be developed in certain places for large power, usually entails excessive first cost; volcanic power or natural steam is used in Italy and Iceland; hydraulic turbines and heat engines alone permit the construction of compact plants of practically unlimited capacity and of moderate first cost. The commonly accepted unit of power is the horsepower, which was defined by James Watt (1736-1819) in 1783 as the equivalent of 33,000 foot-pounds (f.p.) of work per minute. This is about ten times as much work as can be done per minute by a labourer working eight hours per day.

The use of domesticated animals was the first enlargement of the power of man and the beginning of his civilization. The use of the wind for sailing vessels was an early development, but its use in operating windmills dates from about the 12th century. Water wheels were known in Greek times and are described by Vitruvius, but their capacity was very small. To the end of the 18th century the largest water wheels for industrial use did not exceed 10 h.p. The earliest operative heat engine was the cannon, used first at the end of the 13th century. The social consequences of its invention were momentous; it had a great part in the destruction of the feudal system. It represented a greater concentration of power than had been possible previously. Its indirect

influence in stimulating the development of the art of cutting metals is of prime importance in the history of the heat engine.

The special incentive which gave birth to the steam engine was the desire to remove water from mines (particularly the tin mines of Cornwall). In 1698 Capt. Thomas Savery's engine was patented and a number of his engines were built. They were found to be extravagant in their use of coal. Four years later the first steam engine using a cylinder and piston was devised by Thomas Newcomen.

It was while repairing a model of this engine that James Watt made the improvements that resulted in the modern steam engine. In 1782 Watt patented a double-acting rotative engine which for the first time, made steam power available for driving all kinds of mechanism. The result of this invention was the factory system and the Industrial Revolution. It became possible also to apply steam power to navigation and to railroads.

The next important advance in power generation was the invention by Benoît Fourneyron of the hydraulic (reaction) turbine in 1827, for utilizing the energy of water available under high heads. Impulse water turbines of the Pelton type, adapted to use the highest heads, were developed in California about 1860. Hydraulic turbines reached a high degree of perfection, giving efficiencies in excess of 90%.

The thermal efficiency of a heat engine is a function of the maximum and minimum temperatures of the working substance and also of the cycle of operations. The cycle of maximum efficiency for given temperature limits is the Carnot cycle. Combustion, which is the source of heat in heat engines, may occur either outside the engine (external combustion) or inside the engine (internal combustion). In external-combustion engines the working substance is distinct from the products of combustion, and heat travels to it by conduction through containing walls, such as boiler heating-surface. The maximum temperature of the working substance is then limited by the strength of the containing walls at high temperature. With internal combustion the products of combustion are used as the working substance, and there is no maximum temperature limit, since the containing walls, piston and valves can be water-cooled. The theoretical thermal efficiency of the steam turbine is about 36%, of the diesel engine about 50%. The brake thermal efficiencies actually realized are considerably lower. The internal-combustion engine is compact, of light weight, instantly available for use, has low labour cost and no stand-by losses. Its principal disadvantage is that it uses a fuel more costly than coal except in diesel engines utilizing the cheapest grades of oil.

The first practical internal-combustion engine was that of E. Lenoir (1860). Two years later Beau de Rochas showed that for good efficiency it is necessary to compress the explosive mixture before igniting it, and in 1876 this idea was effectively realized in a successful explosion engine by N. A. Otto. The Otto cycle is the standard cycle in automobile, airplane and many stationary and marine engines. The fuel used by Lenoir and Otto was coal gas, but in 1883 Gottlieb Daimler substituted volatile liquid hydrocarbon fuel (gasoline or petrol) and thereby made the engine available for automotive purposes. The use of less volatile hydrocarbon fuels (kerosene, fuel oil, etc.) was first successfully developed by Hornsby in the Hornsby-Ackroyd engine of 1894. A year later Rudolf Diesel built his first engine, in which the air is brought up to the temperature of ignition of the fuel by the work of compression alone and fuel is injected in a finely atomized state after the compression is completed. It is possible to burn in it any fuel that can be atomized by high-pressure air injection, or by spraying under very high pressure through small openings, or by other means. It offers the combination of the cheapest fuel and the highest efficiency of utilization. The diesel engine was slow in development at first because of many practical difficulties, especially from heat stresses. It came into wide use, however, in ships, railway locomotives and motorbuses.

The principal uses for power up to about 1890 were for driving shafting, pumps, compressors and hoists, for locomotives and for marine propulsion. With the improvements that had recently been made in the use of electricity the power station appeared

Electricity is a means for transmission of power and the only means which is economical for long distances and for complicated systems. The earlier power-transmission systems by rope drives, compressed air and water under pressure were too costly and cumbersome to survive.

The history of the development of power shows a constant striving for greater economy, greater compactness of the units and greater capacity of each unit.

POWER BOATS: see MOTORBOAT; BOATING.

POWER OF ATTORNEY is a formal written authority signed by a principal, usually under seal, empowering an agent named therein to act generally or in certain specified matters on the principal's behalf. Powers of attorney are frequently used in land transactions, in which case the agent's authority must be in writing. A proxy to vote stock, or the power signed upon transfer of stock, are other typical uses.

The principal may revoke any power of attorney by notice to the agent, even though it is expressly stated to be irrevocable, unless the power is coupled with some interest making it inequitable to do so. In England, certain short-term powers relating to land are irrevocable by statute, when a consideration has been paid. See AGENCY. (R. T. S.)

POWERS, HIRAM (1805–1873), perhaps the most famous U.S. sculptor of the middle of the 19th century, was born in Woodstock, Vt., on June 29, 1805. He discovered his talent for modeling while working in a waxworks museum in Cincinnati, O., about 1829. In 1835 he set out for Italy to become a sculptor, stopping in Washington to model a portrait of Andrew Jackson (now in the Metropolitan Museum of Art, New York city), which is probably the best portrait he ever made.

He arrived in Italy in 1837 and settled in Florence, where he remained for the rest of his life. Powers' most famous work was the "Greek Slave" (Corcoran gallery, Washington, D.C.), a female nude, which caused a sensation when it was exhibited at the Crystal Palace exposition in London in 1851. High prices were paid for his work. He produced many portrait busts of the prominent American visitors to his studio, where he charmed them with his lively conversation.

Powers died in Florence on June 27, 1873, just when his sculpture and that of his contemporaries was beginning to be supplanted by the work of a later generation.

See Albert Ten Eyck Gardner, *Yankee Stonecutters* (1945); Lorado Taft, *History of American Sculpture* (1924). (A. T. G.)

POWER TRANSMISSION. The appliances for the utilization of natural sources of energy may be classified into three groups: (1) Prime movers, by means of which the natural form of energy is transformed into mechanical energy. To this group belong all such devices as water, gas and steam turbines, steam engines, internal-combustion engines, etc. (2) Machinery of any kind which is driven by energy made available by the prime mover. To this group belong all machine tools, textile machinery, pumping machinery, cranes—in fact every kind of machine which requires any considerable quantity of energy to drive it. (3) The appliances by means of which the energy made available by the prime mover is transmitted to the machine designed to utilize it.

In many cases the prime mover is combined with the machine in such a way that the transmitting mechanism is not distinctly differentiated from either the prime mover or the machine, as in the case of the locomotive. In other cases the energy made available by the prime mover is distributed to a number of separate machines at a distance from the prime mover, as in the multiple pulley-and-belt drives used in early factories. In this case the transmitting mechanism has a distinct individuality.

Finally, prime movers may be located in places where the natural source of energy is abundant (near waterfalls or in the neighbourhood of coal fields), and the energy made available is

transmitted in bulk to factories, etc., at relatively great distances. In this case the method and mechanism of distribution become of paramount importance, since the distance between the prime mover and the places where the energy is to be utilized is limited only by the efficiency of the mechanism of distribution.

This article deals with power transmission by mechanical and hydraulic means. For a discussion of the generation, transmission and distribution of electricity, see ELECTRIC POWER. (X.)

MECHANICAL POWER TRANSMISSION

Mechanical power transmission refers to the transfer of power through and among machines by means of mechanical devices, such as shafts, gears, belts and clutches. Other methods of power transmission, e.g., electrical, are generally used to convey power over long distances. Power can also be transmitted by means of vibrating media, such as sound and electromagnetic waves—as, for instance, in the tremendous force that is effected by an explosive charge. Any moving mass possesses energy and, therefore, power. A flowing river or a blowing wind each possesses power which is available anywhere along its path of travel.

POWER AND ITS MEASUREMENT

Power.—Power is the time rate of doing work. When a body weighing 5 lb. is raised vertically a distance of 4 ft., 20 ft.-lb. of work are performed. In general, work is done whenever a force is moved through a distance; work is the product of force times displacement. Either the force or the displacement must be effective; i.e., either the displacement must be the component parallel to the force direction or the force must be the component parallel to the displacement path.

In fig. 1, for example, the applied force makes an angle of 30° with the direction of motion of the box along the floor. Thus the component parallel to the floor—the effective force—is $100 \times \cos 30^\circ$, or 86.6 lb. The work, then, is 86.6×5 , or 433 foot-pounds (ft.-lb.). The downward component, $100 \times \sin 30^\circ$, or 50 lb., performs no work because the box does not move in the vertical direction.

The factor of time is not considered in this example. On a slick floor the box might have moved 5 ft. in 3 seconds, while on a rough floor the time might have been 30 seconds. The differ-

FIG. 1.—WORK SHOWN AS A RESULT OF FORCE (THRUST OF 100 LB. AT AN ANGLE OF 30°) AND DISTANCE (OBJECT MOVED 5 FT., A TO B)

ence is due to the frictional force between floor and box. What the frictional force does is also work, but the energy is wasted in heating the floor or the box, or both. Less of the total work is left in the second case, and so the box moves (accelerates) slower. The point is that the same amount of work is expended in each case but over a different period of time. In the first case, work is performed at 433/3 or 144.3 foot-pound-seconds (f.p.s.), and in the second case at 433/30 or 14.43 f.p.s. These figures are a measure of power—the time rate of doing work (see POWER; HORSEPOWER).

Mathematically, the time rate of work is expressed as dW/dt —the first derivative of work, W , with respect to time, t . This is the power at any given instant; the average power during some particular time interval is the total work divided by the time consumed: $P_{avg} = W/\Delta t$.

Work performed by a force F on a body which is thereby displaced a distance ds in the direction of the force is Fds ; the power P is Fds/dt . Since ds/dt , the time rate of displacement, is veloc-

ity, power equals force times velocity, or $P = Fv$. Thus, force multiplied by effective velocity is an expression of power.

A torque or moment M , applied to a body will cause it to rotate. That is, the body will undergo an angular displacement $d\theta$ during the time dt . The power involved here is: $P = dW/dt = M_d\theta/dt = M_t\omega$, where ω is the angular velocity. Power is thus the result of force translation along a straight line, torque rotation about a plane, or some combination of the two.

These fundamental definitions can be used to derive the power involved in any particular case. When the force, or torque, and velocity are constant, power is computed, using the finite expressions. When either or both vary, the infinitesimal expressions are applied and integrated. Such cases can become quite complicated, mathematically.

Power Measurement.—Power-delivering machines must be evaluated, because the amount of power being delivered is most important. In numerous cases, power output can be measured at different places. For instance, in the case of an automobile, power can be measured at the output end of the engine or at the wheels. Thus it is possible to measure and identify power in many ways, such as indicated horsepower, brake horsepower, shaft horsepower and friction horsepower (see HORSEPOWER).

In steam, gasoline and diesel engines, the working substance, resulting from the fuel combustion outside or inside the cylinder, exerts a varying force on a moving piston. In a reciprocating compressor and pump, power supplied to the shaft is transmitted to the piston and, in turn, to the working substance. In either case the piston force is variable. This variation must somehow be measured if the power delivered to or by the piston is to be determined. A special device called an indicator is used, and indicated horsepower (i.h.p.) is thus measured.

Of the many types of indicators, probably the most common is the piston type, often called a steam-engine indicator (it was originally designed to measure the power of steam engines). In a device of this type, the piston within the body of the indicator is actuated by the varying pressure within the engine cylinder to which it is connected. Motion of the indicator piston is, in turn, resisted by a calibrated spring and thus moves in direct proportion to the pressure and the spring force. A string fastened to the drum at one end and to the engine crosshead at the other rotates the drum to correspond to the engine-piston motion, giving a record of pressure versus piston displacement on a sheet wrapped around the drum. The area within the indicator diagram, being force times displacement, represents the net work performed by or on the engine piston during each cycle. It is therefore a measure of the engine's power. Actually, power is determined by first computing the mean effective pressure (m.e.p.)—the diagram area divided by the diagram length. The calculation yields the equivalent constant pressure which defines the same amount of work. When the m.e.p. is multiplied by the piston area, the total force is found. This force multiplied by the stroke L and the number of cycles per minute n , and divided by the horsepower factor, yields the indicated horsepower:

$$\text{i.h.p.} = \frac{(\text{m.e.p.})ALn}{33,000} \text{ per piston face}$$

The result, of course, must be multiplied by the number of cylinders (or faces when each side of each piston develops power) present in the engine. Other indicators differ in the type of pressure-sensing unit or recording device; electrical, optical and diaphragm principles have been used.

Power may also be measured at the output end of an engine. A dynamometer, such as the Prony brake, is used for this purpose. The Prony brake is an energy-dissipating device in which friction generates heat. Some dynamometers use fluid friction in place of solid friction; e.g., hydraulic and air dynamometers. In other types, power is converted to electrical energy and dissipated in resistors as heat. Still another type is the torque transmission dynamometer, which measures the power actually being delivered. The power passes through the dynamometer without waste and is delivered by it to the work shaft. It is the angular twist occurring in the dynamometer shaft which is measured; this twist

is directly proportional to the torque and so can be used to obtain the shaft horsepower (s.h.p.). Another transmission dynamometer uses electric strain gauges to sense the twist in the shaft, the strain gauge output being calibrated to yield the torque, which then can be converted into shaft horsepower (see DYNAMOMETER).

Whenever one body slides or rolls over another, friction develops. Friction consumes power, and the power thus lost is called friction horsepower. Friction horsepower is not easy to measure. It can be determined, however, by measuring the power input at zero load; the entire input must be friction power, since external work is not being done. Friction horsepower can also be found by the method of difference: both input and output power, e.g., indicated and brake horsepower, are measured; the difference between the two is loss and so represents friction horsepower.

Any power wasted in friction becomes unavailable to do the machine's work, and thus the machine becomes less efficient. Mechanical efficiency, therefore, can be stated as the ratio of input to output horsepower. It is a measure of an engine's capacity to keep the externally usable power at a maximum; alternatively, it is also a measure of the ability of a machine to use the power supplied it to do useful work.

POWER PRODUCTION

Prime Movers.—Prime movers are power-generating devices, the output of which is used to operate machines. It is immaterial how the power is developed within the prime mover. In some, the energy is created chemically, as the burning gases in the internal-combustion engine; others convert one form of energy into another by physical means. For instance, steam is expanded to yield shaft power in the reciprocating steam engine; i.e., heat is transformed into mechanical power.

The terms prime mover, power source and power plant are often used interchangeably, but differences may exist. A prime mover provides the immediate energy needed to run the machine; the tiny motor powering an electric shaver is a prime mover. A power plant generates power within itself: the automobile engine is a power plant, but it also acts as a prime mover, turning the rear wheels of the car.

Fundamentally, the sun is the source of all power; the equivalent of the energy obtained from 2×10^{14} tons of coal reaches the earth as solar energy each year. If man knew how, he could produce 1 h.p. from the solar energy striking each square yard. Some of this energy is naturally consumed for man's welfare: evaporation and climatic differences, which bring about rain and winds, supply water, water power and wind power; vegetation feeds both man and animal and so generates muscular power; and the vegetation of past ages is available as coal and petroleum.

For practical purposes, discussion must be limited to power sources found on earth in sufficient quantity for man's use. These are muscle, water and wind power, wood, coal, petroleum and natural gas. The direct use of solar energy constitutes another, although as yet minor, source (see SOLAR ENERGY, UTILIZATION OR). Atomic power is a source man has learned to harness only recently, and nuclear reactors are now used as the heat source in steam-power plants and marine propulsion. The only major difference between the ordinary and the nuclear steam-power plant is the replacement of the boiler by the reactor (see ATOMIC ENERGY; NUCLEAR ENGINEERING).

A typical list of prime movers might include: (1) muscles; (2) windmills; (3) sails; (4) water wheels; (5) reciprocating steam engines; (6) spark-ignition engines; (7) diesel engines; (8) hydraulic turbines; (9) steam turbines; (10) gas turbines; (11) jet and rocket engines; (12) electric motors; and (13) springs. The first four are industrially no longer important in much of the world, although they were in the past; however, in technically undeveloped nations they still provide the major portion of the power consumed.

MECHANICAL TRANSMISSION ELEMENTS

Devices which transmit the power output of prime movers to the place of use are transmission elements. Power involves time

force or torque, and velocity. The same power can result from a large force at low velocity or from a small force at high velocity. In one place on a machine one combination may be required; at an adjoining place, the other combination. If both locations are to be supplied by the same prime mover, many transmission elements may have to be interposed. Therefore, the elements may be numerous and complex.

Mechanical transmission elements include such devices as shafts, gears, belt drives, chain drives, couplings, clutches, brakes, power screws, cams, linkages, flywheels and bearings.

Shafts.—The various designs of shafts may be classified for convenience into two groups: transmission and machine shafts. Transmission shafts are those used outside the machine to bring power to it. These may be relatively long and supported at several places. Line shafts and countershafts, so common in older manufacturing plants, were of this type, distributing the power from a single prime mover to machines throughout the plant. In modern plants the single prime mover has been replaced by individual prime movers, one in each machine. Therefore any shafting needed becomes an integral part of the machine and so falls into the second group, machine shafts.

Basically there is no difference between machine and transmission shafts. Both transmit power, and they differ only in length and the number of stations at which power is withdrawn. The diameter depends upon the torque being transmitted and may be just as large on a short shaft as on a long one. In addition to the torque, shafts are subjected to bending forces (transverse to the shaft), if only due to their weight. Thus, flexure, as well as torsion stresses, is always present.

Since shafts are often critical members, they must be properly designed. The amount of twist, as well as the stress, must remain within safe limits. Generally, shafts are made of plain carbon and alloy steels. When greater strength is required, particularly at higher speeds, nickel, nickel-chromium and chrome-vanadium alloy steels are used. Shafts are hot-rolled to standard sizes, and for use under severe fatigue conditions, they are turned and ground or polished to eliminate all surface defects. In addition, they often are given special heat-treatments.

Most shafts are solid and of circular cross section, although they may be hollow, *e.g.*, to carry lubricants on an inner, concentric shaft, and occasionally a power shaft may have a cross section other than circular (*see SHAFT, DRIVING*).

Keyways and keys are an integral part of power shafting. Sometimes a shaft alone is used between the prime mover and load; more often, however, shafts have many other power-transmission elements attached to them. The elements must be fixed rigidly to the shaft, and to assure this, fasteners, such as keys, pins, cotter and splines, are used. These devices are interposed between the shaft and transmission elements to prevent relative motion between them. This often involves keyways along the shaft, as well as fasteners (*see KEYS AND KEYWAYS*).

Gears.—When teeth are placed around the surface of a cylinder, cone or hyperboloid, the member becomes a gear, another power-transmission element. Gears can transfer power from one shaft to another, and the shafts may be intersecting, as well as parallel. The transmission is positive because gears provide meshing surfaces which do not depend upon friction as the driving medium. Power must be transferred at a constant velocity ratio, quietly and with a low friction loss. Such requirements are not easily satisfied. Thus, gear teeth must be of proper profile, dimension, tolerance and finish. Gears having standard profiles but differing in other details are needed to connect the many shaft directions and satisfy other conditions arising in power transmission. The following types have been developed: spur, bevel, hypoid, helical, herringbone and worm. Detailed descriptions and applications may be found in the article **GEARS**.

Belt Drives.—Belts are convenient power connectors when shafts are some distance apart and when an absolutely constant velocity ratio is not essential. Belts usually are used to connect shafts that are parallel, but the flexibility of belts permits other arrangements. Belt-connected shafts can be made to turn in opposite directions by crossing the belt.

BY COURTESY OF THE NATIONAL INDUSTRIAL LEATHER ASSOCIATION

EXAMPLE OF FLAT PULLEY BELT MADE OF LEATHER

Leather is the most common flat belt material, but rubber, balata and textiles are also used. The leather is tanned, mineral tanning being preferred for applications where water, steam and oil are present, and layers of the leather then are cemented to form multiple-ply belts. Belt lengths must be fastened together to form the closed loop needed for a drive. The most efficient joint is the cemented lap joint. A simple type is the rawhide-lacing method; wire hooks and steel loops are also used.

A necessary part of the belt drive is the pulley over which the belt rides. Iron, steel, wood, compressed fibre, and plastic laminates are all used to make pulleys. Split as well as solid pulleys are common, the split type being easy to fasten to a long shaft because the halves can be placed over the shaft and clamped to it. When it is required to stop and start the driven shaft while the driving shaft continues its rotation, a tight-loose pulley combination is useful; the belt is shifted from one pulley to the other by means of a lever arrangement.

The V-belt, having a reinforced trapezoidal section, can transmit more power because of the gripping action between the belt sides and the V-grooved sheave. Most V-belts have a rubber-fabric outer cover surrounding a central portion of cotton- or wire-reinforced rubber. V-belts are made endless and in a sufficient number of standard sizes to meet most needs. Stretch in these drives is best taken up by means of idler pulleys or pivoted motor bases.

A more recent belting development is the toothed belt, which has teeth on its inner surface to engage corresponding spaces on axially grooved pulleys. This arrangement approximates the positive gear drive, and it can be used when a flexible drive capable of synchronizing the shafts is needed. (*See also PULLEY AND BELT*.)

Chain Drive.—When positive power transmission between shafts too far apart for gear connection is desired, chain drives become useful. The greater elasticity of chain drives also provides better shock absorption. In addition, wear is reduced because of the larger contact area.

A chain is a combination of close-tolerance links, pins and rollers. Standard chains are made in two forms: roller chain and silent chain, and they are manufactured in many sizes. Three principal dimensions define the chain: the pitch (length between rollers), the inside width of the chain and the outside diameter of the roller. A special link, easy to assemble and disassemble, is used to fasten the chain ends. Chains ride on sprockets or toothed wheels, the teeth being shaped to mesh precisely with the chain links.

A less refined but equally practical chain drive can be obtained by running a common link chain over a sprocket designed in the form of a pulley with its rim shaped to interlock with the links.

This type of drive is especially useful when heavy loads must be lifted without danger of slippage, as in the anchor windlass and in the differential chain hoist used in maintenance shops. (See CHAIN.)

Couplings.—Couplings are used to join shafts. In general, a coupling is considered a permanent connector, although it can be disconnected for repairs. Both rigid and flexible couplings are made; the latter allow for slight shaft misalignments. Couplings are made in many different styles, the most important of which are discussed in the article COUPLING.

Clutches.—The clutch is a device designed to connect and disconnect a power source and a load. Mechanical-contact clutches are of the positive friction type. Positive clutches contain protruding jaws which engage when the two halves are brought together. The jaws are either square (in which case rotation in either direction may be handled) or spiral (in which case only unidirectional rotation is possible).

The positive clutch is simple, slip-free and light. It does not develop appreciable heat and so can be engaged and disengaged frequently. On the other hand, the sudden engagement and release subjects not only the clutch but also the attached machinery to much shock and wear.

The friction clutch contains two friction surfaces, one on the driving element, the other on the driven element, and some form of linkage to engage and disengage the friction surfaces. Probably the chief advantage of the friction clutch is its ability to slip slightly when first engaged, thus cushioning shocks and reducing wear and stresses. The most common types are discussed in the article CLUTCH.

Brakes.—The mechanical brake, like the clutch, contains two friction surfaces and a mechanism which brings them into contact. The brake absorbs kinetic energy by generating and dissipating heat. Block, band, disk and shoe brakes are common. (See BRAKE.)

Power Screws.—Threaded rods (screws) are often used to transmit power. Lathes, presses, jacks and materials-testing machines are typical of devices employing power-transmission screws. Screw drives are not very efficient, but for slow, powerful motion, they are convenient. The lathe tool-carriage screw (see LATHE) is illustrative of an important trait of the power screw: its ability to convert a rotational force (torque) into a powerful linear (translational) force.

Cams and Linkages.—A cam transmits power by means of a follower in direct contact with it. The contact is either sliding or rolling. The cam itself can take many forms and can impart an infinite variety of reciprocating or oscillating motions to the follower. Because it can be designed to provide nearly any complex motion, it finds much use in automation devices, computers and servomechanisms. (See CAM.)

Like cams, linkages primarily transmit motion, although in some applications they may push or pull a load and in transmitting power become machines. For instance, the power generated at the piston of an internal-combustion engine is transmitted to the crankshaft by means of the connecting rod. The combination is one of the two basic link mechanisms: the slider crank and the four-bar chain. Important linkages of one type or the other are devices like the Scotch yoke, the Whitworth quick-return mechanism, the Geneva wheel, escapements, toggle joints, Hooke's coupling and the straight-line mechanisms. (See LINKAGES.)

Flywheels, Bearings.—These two devices only assist in power transmission; they do not in themselves actually transmit power. Flywheels are attached to a shaft and, because of the large mass involved, absorb and release energy to maintain a more uniform rotation. For example, during the power stroke of a punch press the kinetic energy of the flywheel provides some of the power suddenly needed. Therefore, shaft rotation is reduced but not stopped, as it might be without the flywheel.

Bearings permit motion of one part relative to another with a minimum of friction or power loss, while simultaneously supporting the load on the moving element. They are necessary machine elements in a power-transmission system but do not themselves transmit useful power. (See BEARINGS.) (J. P. V.)

HYDRAULIC POWER TRANSMISSION

A variety of machines use some liquid for developing a push or pull, for moving some object or for controlling some action. Oil, water or some other liquid can be used, but oil is the most common. For practical purposes, it does not change its volume when the pressure is increased. Thus, if oil fills a hydraulic system completely (leaving no air or gas pockets), the motion of a piston can be controlled conveniently and within close limits by the oil flow. Oil lubricates the sliding parts and also prevents rust.

Many complicated hydraulic systems have been developed; however, most of these are essentially combinations of certain simple hydraulic circuits. A study of these simple systems is helpful in understanding the more complicated systems.

Hydraulic Press.—The simple system in fig. 2 illustrates the action of many devices, including the hydraulic press. The two

FIG. 2.—HYDRAULIC PRESS

cylinders are connected by a pipe. There is a close-fitting piston in each cylinder, and liquid in the pipe and cylinders. Assuming no leakage past the piston, the pressure of the fluid is the same in all parts—a statement of Pascal's law (see MECHANICS, FLUID). Essentially the same fluid pressure acts on the face of each piston. Thus a small force F_1 on piston A (small area) can balance a large force F_2 on piston B (large area). In principle, the hydraulic press is analogous to the mechanical lever.

Hydraulic System.—Fig. 3 is an example of a hydraulic system. Oil from a reservoir flows through a pipe into the pump which increases the pressure of the oil. The oil then flows through a pipe into the control valve, which regulates the flow to the cylinder.

A relief valve, pre-set at some safe maximum pressure, is provided for the protection of the system; if the oil pressure should rise above the safe maximum, the relief valve will open and relieve the pressure. Oil entering the cylinder acts on the piston, and this action develops a force on the piston rod which can be used to operate some device. Oil from the cylinder returns to the

FIG. 3.—COMPONENTS OF A HYDRAULIC SYSTEM

reservoir. A filter in the circuit removes dirt and foreign matter from the oil.

As an illustration, assume that the oil pressure produced by the pump is 1,000 lb. per square inch (p.s.i.) and that the piston area over which the oil pressure acts is 3 sq.in. The force on the piston then is $3 \times 1,000$, or 3,000 lb. Thus, a relatively small pressure, acting on a small cylinder, produces a relatively large force to act on some load.

Fig. 3 also illustrates the principle of the hydraulic amplifier. Assuming that the pump produces a pressure of 1,000 p.s.i. in the system, as above, and that a force of 8 oz. is required to move the control valve through its entire range, from fully closed to fully opened, the 8-oz. force can be used to vary the output force on the piston through a range of 0-3,000 lb.

General Features of Hydraulic Systems.—There are three basic parts in the typical hydraulic system: (1) an oil pump; (2) a cylinder or chamber having an actuating piston driven by the liquid; and (3) valves and piping to control the flow of the liquid. The actuating piston can be given any motion desired for control and power. Straight-line reciprocating motion is common, and rotary motion of the driven unit can be accomplished with different hydraulic motors. With these basic features in mind, it is possible to develop different combinations of the simple system.

Hydraulic Pumps and Motors.—In the electric generator, mechanical energy is converted into electrical energy. In the fluid pump, mechanical energy is converted into fluid energy. Therefore, the electric generator and the pump are analogous. Likewise, both the electric motor and the hydraulic motor produce mechanical work, the former from electrical energy, the latter from mechanical energy. The fluid motor may be of either the reciprocating or the rotary type.

Hydraulic machines are of two principal kinds: the dynamic or velocity machine and the positive-displacement or static-pressure machine. In the dynamic or velocity type the action between some mechanical part and a fluid involves significant changes in fluid velocity. The electric fan and the automobile torque converter are examples of the dynamic type.

In the positive-displacement or static-pressure machine the characteristic action is a volumetric change or a displacement action. The hand bicycle pump is an example of the displacement type of hydraulic machine. A positive-displacement machine may have either a fixed or a variable displacement. For example, the internal-combustion engine involves a crank, connecting rod, and piston; the piston displaces a certain fixed volume in the cylinder with each revolution of the crank. If the stroke could be varied, then the displacement could be varied.

The basic hydraulic machine is the plunger pump. It consists of a cylinder fitted with a reciprocating piston, and valves for directing the liquid to and from the cylinder. When acting as a pump, the piston does work on the liquid; the pressure is increased. When functioning as a motor, the liquid does work on the piston.

In a rotary hydraulic pump, work is done by a rotating member on the fluid; the pressure at the outlet is higher than the pressure at the inlet. In a rotary hydraulic motor, fluid pressure is higher at the inlet than at the outlet; the difference in fluid pressure is absorbed by the rotating member to turn the output shaft. Rotary machines are usually classified into three main types, according to the design of the rotating element: gear, vane or piston.

The hydraulic gear pump or motor has a pair of meshing gears in a casing. As the gears rotate, liquid passing through the inlet is trapped between their teeth and the casing and is carried around to the outlet. During each revolution of the gears a certain volume of liquid is transferred from inlet to outlet, so this is a fixed-displacement machine.

The hydraulic vane pump or motor has a rotating member fitted with sliding vanes and set off-centre in a casing. The entering liquid is trapped between the vanes (which ride on the inside of the case) and is carried to the discharge. Both the gear machine and the vane machine are described further in the article PUMP.

Fig. 4 shows the design principles of a hydraulic radial-piston pump or motor. The reaction ring, or housing, and the rotating cylinder block have centres which do not coincide. As the cylinder

ROTATING CYLINDER BLOCK

ENGINEERS' HANDBOOK"; REPRODUCED BY PER-
MISSION OF MCGRAW-HILL BOOK COMPANY, INC.

FIG. 4.—HYDRAULIC RADIAL-PISTON
PUMP OR MOTOR

block rotates, the pistons in the cylinder block execute a reciprocating motion in a radial direction. By means of a valve arrangement, the liquid moves in and out of the machine at the centre of the cylinder block. The displacement of this machine can be varied by altering the distance between the centres of the cylinder block and the housing.

Various arrangements of axial-piston machines have been devised. Fig. 5 illustrates the features of one arrangement of a hydraulic axial-piston pump or motor. The pistons move back and forth in the cylinder block in a direction parallel to the axis of rotation of the cylinder block; this explains the term "axial-piston." The liquid enters and leaves the piston chambers, or bores, at the left end of the cylinder block, which is suitably arranged with a valve plate. The axis of the rotating shaft (either driver or driven) is set at an angle with respect to the axis of rotation of the cylinder block. As the shaft rotates, the piston connector actuates the piston; in one revolution of the shaft, each piston has reciprocated back and forth. This machine can be arranged for a variable displacement by varying the angle.

Standard gear pumps and motors are available for pressures of 2,000 p.s.i. or more, and gear motors are rated to deliver up to 20 h.p. Vane pumps and motors are made for the same pressures, and vane motors will deliver up to 125 h.p. Rotary piston pumps and motors are built for pressures of 5,000 p.s.i. or more, and the motors have outputs of as much as 150 h.p.

Valves.—In hydraulic systems one of the most common types of valve is the piston or spool valve (fig. 6). As shown in the figure, fluid enters port A, passes through the valve body and leaves at port B. By sliding the valve stem, the ports A and B could be blocked by a spool. Various arrangements of ports and spools can be used to get different types of flow control.

Accumulators.—Some hydraulic systems include an accumulator, which is a device for storing fluid energy. An air accumulator is a closed chamber, partly filled with air, into which the pump supplying hydraulic power to a machine delivers liquid while the machine is not working at full capacity. Such an air cushion is used on many reciprocating water pumps. The main purpose of the accumulator is to allow hydraulic machines, such as lifts and presses, to work for a short time at a greater rate than the pump can supply energy. The accumulator acts as a pressure regulator; it serves to damp out pressure surges and shocks in the system.

Hydraulic Transmissions.—Various methods can be used to connect two rotating shafts. In many cases purely mechanical connectors are suitable: gears, chain drives, clutches. In other applications, however, service requirements are best met with some form of hydraulic connector or transmission. In practice two types of hydraulic transmissions are commonly found: (1)

FIG. 6.—PISTON OR SPOOL VALVE

the static or displacement transmission; and (2) the hydraulic, hydrodynamic or dynamic coupling (see TORQUE CONVERTER).

Displacement Transmission.—The hydraulic displacement transmission is a combination of a rotary pump and a rotary motor connected by piping. The pump may be some distance from the motor, or the two may be mounted in a single housing.

This type of transmission has several advantages. For example, the output shaft can be maintained at a constant speed despite a varying input-shaft speed. The direction and speed of the output shaft can be controlled remotely and accurately, and a fixed power output can be maintained over a range of speeds. Automatic overload protection can be maintained, and power consumption can be kept low.

There are four major combinations of pump and motor in a displacement-type transmission.

In the first, a variable-displacement rotary pump is connected to a fixed-displacement hydraulic motor. For a constant work load, a variation in the output-shaft speed will result in an almost constant output torque and variable power. Constant-torque hydraulic transmissions are used on machine tools and conveyors.

A second arrangement couples a fixed-displacement rotary pump with a fixed-displacement rotary motor; there is a flow-control valve in the connecting line to vary the rate of oil flow to the motor. If the load on the output shaft is constant, the output torque will be constant and the power will vary proportionally with the speed.

In a third arrangement, a fixed-displacement pump is connected to a variable-displacement motor. There are various applications, as in machine-tool spindle drives, in which it is desired to maintain constant output power as the output speed is varied. This condition can be realized by varying the hydraulic motor displacement; in this case the output torque decreases as the speed increases.

Finally a variable-displacement pump may be connected to a variable-displacement motor. This combination gives different variations in output-shaft speed, torque and power.

Hydraulic Coupling.—A hydraulic coupling is a combination of a centrifugal pump and a hydraulic turbine. It is sometimes called a hydraulic flywheel, primarily because it reduces torsional vibrations. The action of a hydraulic coupling can best be illustrated by two ordinary electric fans set facing each other. One fan is started by switching on the electric current; its blades rotate, the air flow turning the blades of the other fan. In the hydraulic coupling, the rotating input or primary shaft drives a centrifugal-pump runner or impeller. This usually has straight radial vanes or blades; in construction it resembles a grapefruit half, with the fruit removed. As the pump runner builds up speed, kinetic energy is added to the fluid, which flows outward along the vanes, crosses a gap and enters the turbine runner. Usually the turbine runner is similar in construction to the pump impeller, with straight radial blades. After sufficient energy has been developed, the liquid turns the turbine runner, which is connected to output or secondary shaft. There is no mechanical connection between the input and output shafts; the linkage between them is solely through the medium of the moving fluid.

Since there are no torque-reacting members in the hydraulic coupling other than the pump impeller and the turbine runner, the output torque always equals the input torque for steady operating conditions. The speed of the input shaft always exceeds that of the output shaft. At the start of operation, the input shaft rotates while the output shaft remains stationary; the "slipage" is 100%; at normal speeds and loads, the slip may be low as 1%–4%. The efficiency of the coupling is defined as the ratio of the power output to the power input. At normal speeds and loads, the efficiency of a hydraulic coupling is high; it may be 95%–99%. Torsional vibrations or shocks on either shaft of the hydraulic coupling are damped by the fluid. The load on the output shaft may be stalled without stalling the driver or input shaft. Hydraulic couplings have been built with capacities ranging from 1 to 36,000 h.p. In some automotive transmissions, a hydraulic coupling is added, along with the gearbox, in the power drive between the engine and the rear wheels. The hydraulic coupling is

not a substitute for the gearbox: the gearbox is used to change the torque, whereas the hydraulic coupling does not change the torque. The hydraulic coupling merely serves to cushion shocks.

A variant of the hydraulic coupling is the electromagnetic clutch which contains a fluid suspension of paramagnetic particles (e.g. a compound of iron). When an external magnetic field is applied, the fluid suspension becomes almost solidified and capable of transmitting torque. (R. C. Br.)

POWHATAN. This group of Algonkian Indian tribes in the tidewater portion of Virginia and southern Maryland had been welded into a confederacy, by the conquests of an able chief known by the same name, shortly before the settlement of Jamestown in 1607. His daughter Pocahontas (q.v.) married John Rolfe. After Powhatan's death the Indians massacred 347 British settlers in 1622. Fourteen years of relentless warfare followed until the Indians submitted, only to rise again in 1644 and slay 500 whites. The war that followed broke them, and though in 1669, 2,100 remained of the original 8,000, they dwindled to about 700, mixed with Negroes and whites, and were known as Chickahominy Pamunkey and by other tribal names. In the 1960s an estimated 3,000 Powhatan were reported, largely scattered along the Virginia coast. See also ALGONKIAN TRIBES.

See J. R. Swanton, *The Indian Tribes of North America* (1957); F. W. Hodge (ed.), *Handbook of American Indians North of Mexico* (1959). (A. L. K.; X.)

POWIS, EARLS AND MARQUESSES OF. The Welsh principality of Powis, comprising the county of Montgomery and parts of the counties of Brecknock, Radnor, Shropshire, Merioneth, and Denbigh, was subject to the princes of North Wales from about the 9th to the 13th century. In about 1200 it was divided into North and South Powis. It seems clear, however, that OWEN AP GRUFFYDD AP GWENWYNWYN (d. 1293), who succeeded his father in 1286, held his lands in South Powis of Edward I as an English barony. Owen's only son, GRUFFYDD ap OWEN (d. 1309), died without issue, and the lands and the lordship of Powis went with Owen's daughter Hawise to her husband, JOHN DE CHERLETON or Charleton (d. 1353). Their great-grandson, EDWARD, died in 1421 without male issue and the barony fell into abeyance between Edward's two daughters.

SIR RICHARD GREY (1436–1466), of "Pole" (Welshpool), as "Dominus de Powes" swore allegiance in Parliament to Henry VI in July 1455. On the death without legitimate issue of his great-grandson EDWARD GREY, in 1551, the barony fell into abeyance and became extinct. However, Edward instituted his illegitimate son EDWARD universal heir; this Edward in 1587 alienated the lordship and castle of Powis to SIR EDWARD HERBERT (d. 1595), second son of William Herbert, earl of Pembroke. Edward Herbert's son, WILLIAM (c. 1573–1656), was created Baron Powis of Powis on April 2, 1629. During the English Civil War he held the castle for Charles I. His grandson, WILLIAM (c. 1626–1696), was created earl of Powis on April 4, 1674, and Viscount Montgomery and marquess of Powis on March 24, 1687. From 1678 to 1687 he was in the Tower of London, accused of complicity in the Popish plot. In 1688 he followed James II into exile and was created duke of Powis by the dethroned king. WILLIAM (c. 1662–1745), 2nd marquess, also suffered as a Jacobite. When his son WILLIAM (c. 1698–1748) died unmarried, the titles became extinct. In 1748 HENRY ARTHUR HERBERT (c. 1703–1772), who had been made Baron Herbert of Chirbury in 1743, was created Baron Powis and earl of Powis. The title again became extinct at the death of his son GEORGE EDWARD HENRY ARTHUR in 1801, but George's only surviving sister Henrietta Antonia married

EDWARD CLIVE (1754-1839), Baron Clive of Plassey (son of the soldier Robert Clive), who was created Baron Powis and earl of Powis on May 14, 1804. The title has remained with his descendants, who took the surname Herbert, and the present holder, **EDWARD ROBERT HENRY HERBERT (1889-)**, 5th earl of Powis is his great-grandson.

POWYS, the name of three outstanding English writers, sons of the Rev. C. F. Powys. **JOHN COWPER POWYS (1872-1963)**, was born at Shirley, Derbyshire, on Oct. 8, 1872, and educated at Sherborne School and Corpus Christi College, Cambridge. He was a university extension lecturer for some 40 years, 30 of them in the United States. He died at Blaenau Ffestiniog, Merioneth, North Wales, on June 17, 1963. His works include poetry, philosophy, literary criticism, a striking *Autobiography* (1934), and the series of long, panoramic novels on which his fame chiefly rests, including *Wolf Solent* (1929), *A Glastonbury Romance* (1932), *Owen Glendower* (1940), and *Porius* (1951).

THEODORE FRANCIS POWYS (1875-1953), was born at Shirley on Dec. 20, 1875, and died at Mappowder, Dorset, on Nov. 27, 1953. He was educated privately and became a farmer, soon abandoning this to live on a small private income. He began to write early, but was slow to publish; two small essays in philosophy attracted little attention, but in 1923 *The Left Leg* introduced him to a wider public; thereafter his short stories were collected at intervals—*The House with the Echo* (1928), *The White Pater-noster* (1930), and others—and he published eight novels, of which *Mr. Weston's Good Wine* (1927) is the best known; this beautiful allegory of the wines of Love and Death is unique in English fiction. T. F. Powys had also a gift for ironic humour, best seen in *Kindness in a Corner* (1930).

LLEWELYN POWYS (1884-1939), was born at Dorchester, Dorset, on Aug. 13, 1884, and died at Clavadel, Switzerland, on Dec. 2, 1939. He was educated at Sherborne and Corpus Christi, Cambridge. Though early stricken with tuberculosis he lived a full life, traveling widely and commenting on all he saw, in such books as *Ebony and Ivory* (1923), *The Verdict of Bridle-goose* (1926), *A Pagan's Pilgrimage* (1931), and *Earth Memories* (1934). He wrote mainly in essay form, hedonistic reflections on life, sensitive reflections on nature and country manners, and appreciations of idiosyncratic writers like Thomas Deloney and Sir Thomas Browne. His last and best book was the "imaginary autobiography" *Love and Death* (1939), a love story distilling the reflections of a lifetime.

No three writers could be more dissimilar. John Cowper works on a vast canvas crowded with characters, and Theodore within the confines of a Dorset hamlet, his cast a few villagers. John Cowper works out complex permutations of character, interweaving motive and event; Theodore sees all in black and white, good or evil, without compromise. His style is spare and strange, full of beauty, irony, and horror, deceptively simple. John Cowper's style is eloquent and rhetorical, a great spate of words which cannot be stemmed. Llewelyn Powys, almost entirely neglecting fiction, was the most consciously propagandist, proclaiming the delights of the senses and the bounty of the sun.

Others in this remarkable family of 11 children were Littleton (1874-1956), a headmaster of Sherborne Preparatory School, author of two volumes of autobiography; Gertrude (1877-1952), a painter; Albert Reginald (1881-1936), an architect long associated with the Society for the Protection of Ancient Buildings; Marian (1882-), an internationally celebrated expert on lace; and the poet and novelist Philippa (1886-1963).

P'O-YANG, a lake in northern Kiangsi Province, China, is a rapidly silting up flood reservoir for the Yangtze River at the northern end of the basin, the drainage of which coincides with the area of Kiangsi Province in central China. The lake covers an area of 1,073 sq.mi. (2,780 sq.km.) and is 70 ft. (21 m.) deep at high water, but shrinks greatly during the dry winters. Through its flood plain flows its chief river, the Kan Chiang, from the south,

the Lo-an Shui and Hsin Chiang from the east, and the Hsiu Shui from the northwest. River steamboats navigate between the lower reaches of these and the narrow northern P'o-yang arm to reach the Yangtze at Huk'ou. (H. J. Ws.)

POYNINGS, SIR EDWARD (1459-1521), lord deputy of Ireland from September 1494 to December 1495, mainly remembered for the laws, called after him, which subjected the Irish Parliament to the control of the English king and council, the son of Robert Poynings and grandson of Robert, 4th Baron Poynings, was probably born at Southwark. His mother was Elizabeth, daughter of William Paston. A rebel (1483) against Richard III, Poynings attached himself to Henry Tudor, earl of Richmond, who employed him after his accession as Henry VII in military offices at Calais and elsewhere. Yorkist pretenders against Henry VII having secured support in Ireland even from the lord deputy Gerald Fitzgerald, 8th earl of Kildare, Henry decided to experiment with a regime of military and financial experts who would attack the Yorkists in the field, take statutory steps to prevent the king's government in Dublin being utilized against him, and endeavour to revive the king's revenue which had virtually disappeared. In 1494 Poynings was put in charge of this program (see *IRELAND: History*).

From the military standpoint, Poynings was successful in driving the Yorkist pretender, Perkin Warbeck, out of Ireland. He was less successful against the Ulster Irish lords, and was obliged to abandon his military expedition, thereby losing any chance of reducing the whole of Ireland to obedience.

Poynings' legislative measures earned him a lasting, if unsought fame. As part of the policy of imposing upon the English colony in Ireland laws now enforced in England, 49 statutes were passed at a parliament held at Drogheda in the years 1494-95. Of these, two measures subsequently came to be associated with the name of Poynings. The first applied all recent English public laws to Ireland; the second and more famous one subjected the meetings and legislative drafts of the Irish Parliament to the control of the English king, and of his English council (but not of the English Parliament). Thereafter until 1782 Parliament could not legally meet in Ireland until licensed to do so by the English lord chancellor, and until the causes for the meeting and the bills to be put before it had first been approved by the king and his English council. Moreover, as draft legislation had to be approved by the king in council before being put before the Irish Parliament, amendments to government measures could not be introduced in Ireland.

The measures taken to revive revenue were not successful. The Dublin administration actually became too costly for Henry VII, who ultimately decided to recall Poynings (December 1495); Poynings was subsequently appointed warden of the Cinque Ports. Under Henry VIII he helped to negotiate the Holy League in 1513. He died at Westenhanger, Kent, in October 1521.

See A. Conway, *Henry VII's Relations with Scotland and Ireland, 1485-1498* (1932). (R. D. Es.)

POYNTING, JOHN HENRY (1852-1914), British physicist, discoverer of Poynting's vector that describes energy flow, and experimenter in gravitation, was born at Monton, near Manchester, on Sept. 9, 1852. He studied at Owens College, Manchester, and at Trinity College, Cambridge. He was bracketed third wrangler in 1876. Poynting went as demonstrator in physics to Owens College, but returned to Cambridge in 1878 on his election as fellow of Trinity College. In 1880 he was appointed professor of physics at the Mason College, which afterward became the University of Birmingham. He retained this post until his death at Birmingham on March 30, 1914.

Poynting carried out experiments over a period of 12 years to determine the gravitational constant and the mean density of the earth. He used a balance method and during the course of his experiments added considerable knowledge to the technique of accurate weighing. (See *GRAVITATION: Poynting's Experiment*.) Poynting's best-known work is that in the papers "On the Transfer of Energy in the Electromagnetic Field" (*Phil. Trans. A.*, 1884) and "On the Connection between Electric Currents and the Electric and Magnetic Induction in the Surrounding Field" (*Phil.*

Trans. A., 1888). In the first paper Poynting showed that the flow of energy at a point could be expressed by a simple formula in terms of the electric and magnetic forces at that point. This is known as Poynting's theorem and the vector is also called by his name. Poynting also wrote papers on radiation and the pressure of light and several books.

POZNAN (Polish POZNANSKIE) is the second largest *województwo* (province) in Poland, with an area of 10,318 sq.mi. (26,723 sq.km.) and a population (1960) of 1,992,758. The province lies within the north European plain. The Kocie Mountains, to the south, rise only to 932 ft. (284 m.) above sea level. The region has natural east to west communications; its central axis is the Warta River, navigable from the mouth of the Prosna. Lakes of glacial origin occur mainly in the northern and western parts of the province, most of them in Kujavia, near Goplo Lake. The postglacial soils are not particularly fertile, but careful cultivation and artificial fertilizers produce some of the highest yields in Poland. Agriculture and livestock breeding employ about four times as many people as do industry and crafts. Pig breeding is of the highest quality in Poland. The large amounts of agricultural and animal produce support the local food industry (sugar, meat products, potatoes, fruit and vegetable products, and distilling) and provide exports.

The chief mineral wealth is brown coal, rock salt, and potash, which occur (the salt as salt plugs) in the comparatively recent Kujavia and Pomerania anticline formations, (see Bydgoszcz). A new industrial region was established in 1949–55 near Konin, based on brown coal and potash salt from the region of Klodawa. The long-established building-material industry and glass and porcelain manufacture are based on local Pliocene loam and post-glacial sands. The metal and machine industries, both well developed since World War II, are important.

Settlements are evenly distributed throughout the province. About 35% of the population is urban. The largest towns include Poznan, Kalisz, Gniezno, Ostrow Wielkopolski, and Pila (*qq.v.*).

(K. M. Wr.)

History.—Poznan is the cradle of the Polish state. From very early times it has been known as Wielkopolska, or Great Poland, as opposed to Malopolska, or Little Poland, to the southeast. From 1138 to 1314 Wielkopolska was one of the autonomous Polish principalities within a form of a federal Polish state. After the reunification of the Kingdom of Poland under Wladyslaw I (Lokietek), Poznan shared the fate of the united country.

At the first partition of Poland, in 1772, the districts to the north of the Notec River fell to the share of Prussia. The rest of the province followed in 1793. In 1807, after the Peace of Tilsit, the province was incorporated in the Duchy of Warsaw, but in 1815 it reverted to Prussia as the grand Duchy of Poznan. During the first decades after the Congress of Vienna the Prussian regime was, on the whole, conciliatory, and Prince Antoni Radziwill, a Polish nobleman, was appointed lieutenant governor of the province; there was a provincial assembly and local representative bodies. At the end of 1830, however, a new policy was inaugurated with the presidency of E. H. von Flottwell: the experiment of settling subsidized German colonists on Polish soil (started by Frederick the Great after the first partition of Poland) was resumed, and the Polish language was deprived of its position of equality with German in the government offices, law courts, and schools.

In 1848 Poznan revolted against Prussian rule, but this armed rising was suppressed and a policy of stricter germanization was applied. In the period of Kulturkampf, 1872–74, German became the language for all teaching. Polish was not allowed except for religious instruction and in the two first classes of the primary schools. In 1900 Polish was completely eliminated by the decision that even the catechism must be taught in German. This measure provoked, in 1901, the incident of Wrzesnia (the protest of Polish mothers who took the part of their children when the latter were beaten by the schoolmasters for refusing to say the Lord's Prayer in German) and, in 1903, the famous children's

strike, which lasted for more than a year.

The sharpest battle that the Poles had to sustain in defense of their nationality was the struggle for the soil. It was marked by three laws: the Colonization Law (April 26, 1886); the law forbidding building (Aug. 20, 1904); and the Law of Expropriation (March 20, 1908). In enforcing these laws Germany spent 1,300,000,000 gold marks (mainly in Poznan, but also in Pomorze and Upper Silesia) between 1886 and 1914. Bismarck established the form of this policy, and Bernhard von Bülow continued it. But the Poles would not give in. The report of the Commission on Colonization (*Ansiedlungskommission*), prepared in 1906, on the 20th anniversary of its foundation, stated: "Incontestably the Poles have increased their material force. Their national consciousness has become stronger."

In 1910 the Provinz Posen, as it was called, covered an area of 11,193 sq.mi. (28,990 sq.km.) and had a population of 2,099,831, of which, according to the German census, only 61% were Poles. Those "61%," however, shortly after the Armistice of Nov. 11, 1918, rose on Dec. 27 and shook off German domination.

The Treaty of Versailles did not restore Poznan to Poland according to its historic frontiers, but left certain border districts in Germany. This newly defined Poznan had an area of 10,242 sq.mi. (26,527 sq.km.) and a population of 1,967,865 (1921 census), including 327,846 Germans. Ten years later the total population was 2,106,500, including 173,500 Germans. A change in the administrative division of Poland took place on April 1, 1938. Certain northern districts of Poznan (for instance, Bydgoszcz) were given to Pomorze, while certain others, which had previously belonged to the province of Lodz (Kalisz, Kolo), were added to Poznan. As a result, its area was increased to 10,899 sq.mi. (28,228 sq.km.) and its population (1931 census) to 2,339,600.

During World War II Germany annexed the whole of western Poland. Poznan was called Gau Wartheland, and even Lodz (renamed Litzmannstadt) was added to it. After the war, when the formerly German lands east of the Oder-Neisse frontier were included in Poland, the province of Poznan was temporarily extended westward up to the Oder, but on July 6, 1950, when a new province of Zielona Gora was created in the west, Poznan returned, with a few exceptions, to its 1938 boundaries. (K. Sm.)

POZNAN, one of the oldest cities of Poland, is the capital of the Poznan *województwo* (province) and the seat of a Roman Catholic archbishopric. Pop. (1960) 408,132. The city lies in the great Polish plain, halfway between the Sudety (Sudeten) Mountains and the Baltic Sea and on the navigable course of the Warta River, a tributary of the Oder. In this sector the Warta flows northward, linking two parallel east-west valleys (*pradoliny*), a natural communication which has always served commercial functions throughout the history of Poznan. The city today is on the direct rail and road routes between Warsaw and Berlin and has rail links with all the larger Polish towns. It has air services to Szczecin (Stettin), Warsaw, and Lodz, and an inland port on the Warta.

The oldest part of the city lies in the fork formed by the two arms of the Warta and the Cybina, its right-bank tributary. There became known as the Cathedral Island or Ostrow Tumski. There, in 968 the first Roman Catholic cathedral of Poland was erected, in Romanesque style. It was rebuilt in Gothic style in the 14th and 15th centuries, and again in the 18th century. Badly damaged during the 1945 fighting, it was again rebuilt in Gothic style. The Golden Chapel (1837), a Raczyński foundation, escaped destruction; it contains the tombs of the first two kings of Poland, Mieszko (Mieczyslaw) I and Boleslaw I the Brave. The smaller Gothic St. Mary's Church (1434) and the Baroque archbishop's palace (1732) stand nearby.

In the 13th century a new town (now known as the Old Town or *Stare Miasto*) began to grow on the left bank of the Warta. Its centre was occupied by the Old Market Place with a town hall built about 1300 in Gothic style; after the great fire of 1536 it was rebuilt in 1556–60 in Renaissance style; destroyed in 1945, it was restored to its former magnificence to become a museum.

Toward the end of the 18th century the city grew farther westward. New streets were constructed around a wide rectangular

square (1803), named Freedom Square in 1919. The most remarkable building facing the square is the Neoclassic Raczyński Library (1829); this, too, was destroyed in 1945; it was rebuilt in 1956. In 1905–10 William II, the German emperor, built in the western part of the city a neo-Romanesque castle, which after Poland's restoration housed some faculties of the university and became the new city hall after 1945. The city walls, built by the Germans in the mid-19th century, were dismantled in 1902 and replaced by a green belt, but the citadel on the north side remained. The town area was increased by including the suburbs of Srodka (east), Wilda (south), Jezyce and Lazars (west), and Górczyn (southwest).

Poznań is a cultural and scientific centre for the whole of western Poland. It has seven higher educational establishments including the Adam Mickiewicz University (founded 1919) and many other cultural and educational institutions. It contains Poland's oldest zoological garden, one of the largest collections of palms in Europe, and a fine botanical garden.

The city is one of the largest industrial and trade centres in Poland. The International Poznań Trade Fair, inaugurated in 1921, is held there annually, as well as local trade fairs. The industry of Poznań employs nearly half of all those employed in industry in the Poznań *województwo*. The chief industry is metal-hurgy, and agricultural implements are manufactured. Also well developed are chemical, clothing, food, and printing industries.

(K. M. Wł.)

History.—Poznań was founded as a fortified place with a castle in the 10th century. It became the see of the first Polish bishop (968) and the first (together with Gniezno) capital of Poland. In 1253 Poznań was granted municipal autonomy, and in 1394 King Władysław II Jagiełło gave the city staple right for all wares passing from Poland into Germany and from Germany into Poland. The German settlers, who began to arrive about 1250, were gradually assimilated. From the mid-15th century to the beginning of the 17th century the city prospered and became a centre of the Polish Renaissance and Reformation movement. The Lubrański Academy, the first humanist institution of higher education in Poland, was founded there in 1519.

The Swedish wars of the mid-17th century and the Northern War at the beginning of the 18th century ruined the city. Its revival at the end of the 18th century was interrupted by its annexation by Prussia at the second partition of Poland in 1793. From 1807 to 1815 Poznań was part of the Duchy of Warsaw, afterward reverting to Prussia.

Under the German regime, especially during 1830–48, the city was a centre of Polish cultural and social progress and political conspiracy. After the unsuccessful rising of 1848 measures of repression against Polish organizations followed, but a resolutely anti-Polish and anti-Roman Catholic policy on a large scale was originated by Otto von Bismarck, and was carried out after 1871. Poznań then became the bulwark of the Poles in their successful struggle against germanization. In 1886 the Commission on Colonization was established in the city to buy up Polish land for German colonists. The Poles countered by cooperative credit organizations in which both peasants of the countryside and the middle class of the town took a prominent share. Aleksander Jackowski (1816–1905) and Father Piotr Wawrzyniak (1849–1910) were the main organizers of this economic resistance movement; soon the Poles succeeded in buying more land than they lost.

In 1894 the creation of a subsidized *Deutscher Ostmarkenverein* (nicknamed H.K.T. by the Poles from the initials of its three founders) for the promotion of German advance in the east, the great increase of the funds at the disposal of the Commission on Colonization, and the financing of a campaign against the Polish middle class all proved insufficient, and Bernard von Bülow, the German chancellor, brought, in 1904 and 1908, new legislative means to bear. They were, however, largely rendered futile by the disciplined organization of the entire Polish element, as well as by its continuous growth. Poznań and its countryside shared in the material progress of Germany after 1871. Between that year and 1910 the city's population increased from 56,000 to 156,000.

On Dec. 27, 1918, the city rose against the Germans, shaking off a 103-year occupation. In September 1939 the Germans returned to Poznań for more than five years. In January–February 1945 the city became a battlefield for the retreating Germans and the victorious Soviet forces. By the 1950s the city's rebuilding was completed. Although remaining the chief town of the province, Poznań in 1956 became an independent administrative unit. The famous strike at the Cegielski metallurgical plant on June 28, 1956, was the beginning of a national process of liberalization.

(Jz. A. Z.; H. J. Z.)

POZZO DI BORGO, CARLO ANDREA, COUNT (1764–1842), Corsican nobleman who became a Russian diplomat and was a conspicuous champion of French interests after the Napoleonic Wars, was born at Alata, in Corsica, on March 8, 1764, four years before Genoa's cession of the island to France; he was educated at Pisa. On the outbreak of the French Revolution he was one of two delegates sent to the National Assembly in Paris to demand the political incorporation of Corsica in France; and he was subsequently a Corsican deputy to the Legislative Assembly (1791–92). In early life, through his family, he had been closely associated with Napoleon and Joseph Bonaparte, but on his return to Corsica he found himself in opposition to them: he took the side of Pasquale Paoli (*q.v.*) while the Bonapartes were veering to the Jacobin side. Elected official chief of the civil government, he was summoned, with Paoli, to appear before the Convention in Paris, but ignored the summons and favoured the English protectorate over Corsica (1794–96), during which he was president of the council of state under Sir Gilbert Elliot. When the French occupied Corsica, he fled to Italy, then to England. Having accompanied Elliot (by then Lord Minto) on an embassy to Vienna in 1798, he stayed there for most of the following six years.

In 1804, through the influence of Prince Adam Czartoryski, Pozzo served as Russian commissioner with the Anglo-Neapolitan army in 1805 and with the Prussian in 1806 and was entrusted with an important mission to Constantinople in 1807, before the Tilsit alliance between the Russian emperor Alexander I and Napoleon. This alliance caused Pozzo to retire to Vienna and thence to London. He was recalled by Alexander in 1812 and went on a successful mission to obtain Sweden's collaboration against the French. In 1814, on the downfall of Napoleon and the entry of the Allies into Paris, Pozzo, now a Russian general, became high commissioner to the provisional government of France; and at the Bourbon restoration he was appointed Russian ambassador to the French court. He was present at the Congress of Vienna and joined Louis XVIII of France in Belgium during the Hundred Days in 1815. There he negotiated with the duke of Wellington, who objected strongly to Alexander's idea of consulting the people of France about their future form of government.

In Russia, Pozzo's attachment to the Bourbon dynasty was considered excessive, and indeed during the early years of his residence in Paris he laboured constantly to lessen the burdens laid on France by the Allies and to shorten the period of foreign occupation—so much so that the French government made him a count (1825) and that it was even suggested that he should become France's foreign minister.

The accession of Charles X of France, whose reactionary tendencies he had always disliked, undermined Pozzo's influence in Paris; but after the Revolution of 1830, he smoothed relations between France and Russia when Nicholas I was reluctant to recognize Louis Philippe as king of the French. Fear lest Pozzo's Francophile sympathy should damage Russian interests ultimately led to his being transferred to London (1835). There his health suffered; and on retiring from the Russian service (1839) he moved to Paris, where he died on Feb. 15, 1842. His diplomatic correspondence with the Russian minister Karl Nesselrode was edited by Charles Pozzo di Borgo in two volumes (1890–97).

See A. Maggiolo, *Corse, France et Russie: Pozzo di Borgo, 1764–1842* (1890); P. Ordioni, *Pozzo di Borgo . . .* (1935). (G. A. L.N.)

POZZUOLI, an ancient seaside town in the Province of Napoli (Naples), region of Campania, south Italy, lies 5 mi. (8 km.) W of the city of Naples, and is an episcopal see. It stands on a promontory of volcanic tuff, almost marking the centre of the Gulf

of Pozzuoli separating Cape Posillipo (east) from Cape Miseno (west). Pop. (1961) 52,640 (commune). The intense volcanic activity characteristic of this area has given rise to thermal springs and to changes in the level of the land which has caused buildings to be submerged beneath the sea. The countryside is fertile and picturesque and the climate is mild.

Many traces of the Roman city of Puteoli remain nearby, including a well-preserved amphitheatre (1st century A.D.); baths; and a necropolis with stuccoed and painted underground chambers. The cathedral of S. Procolo incorporates several columns of the Temple of Rome and Augustus. In it is buried the composer G. B. Pergolesi (1710–36), who died at the neighbouring monastery of S. Gennaro (St. Januarius). Temple porticoes along the shore have been drowned by the sea as a result of earth movements. Semisubmerged is the old Roman market (erroneously called the Temple of Sarapis) of the 1st century A.D., which consists of a quadrangle with central courtyard and an arcade with merchants' booths. Inland, to the northeast, is the famous solfatara (called by the Romans the Forum of Vulcan), a semiactive volcano which exhales sulfurous vapours and gives vent to liquid mud and hot mineral springs. Along the coast to northwest is the Monte Nuovo, a volcanic cone which arose after eruptions in 1538.

Pozzuoli is on the Rome-Naples railway line. The people engage in fishing; food processing based on the abundant local fruit and vegetable produce; and the manufacture of machinery. The local volcanic material is used for making the fine cement called pozzolana from the name of the town (see CEMENT). Thermal baths are provided for visitors.

Ancient Puteoli was founded c. 529 B.C. by Greek emigrants and called by them Dikaiarkeia, "city of justice." Rome captured it in the Samnite wars; it was vainly besieged by Hannibal in 214. From 194 it had the status of a colony. Its port made it a leading commercial centre and, indeed, a cosmopolitan city. In A.D. 60 St. Paul spent a few days at Puteoli while on his way to Rome as a prisoner (Acts 28:13, 14), and found a Christian group already in existence there. The town's fortunes declined with the chaos that accompanied the end of the empire, and local volcanic and seismic activity caused most of the people to move to Naples.

(M. T. A. N.)

PRABHU, a member of a group of important scribe castes of Maharashtra (q.v.) in western India, numbering about 30,000 in the 1960s. More than 20,000 of these were Chandraseni Kayastha Prabhus concentrated in Thana and Kolaba districts and in Bombay city; the smaller Pathare Prabhu and Dhruv Prabhu castes respectively are located mainly in Bombay and Poona cities. Prabhus are the equivalent of the Kayastha writer castes in Bengal and northern India. Like the northern Kayasthas, Prabhus claim membership in the Kshatriya (q.v.) varna (class) of rulers and warriors by descent from Prince Arjuna of the Mahabharata epic; they name Chitrugupta, the Brahman (q.v.) accountant for the god of death, as a maternal ancestor. Prabhus have claimed historical ties with classical rulers of Oudh and Bihar, but are first clearly documented as accountants in Muslim service during late medieval times. Administrators and soldiers for the Maratha (q.v.) kings and peshwas, the Prabhus were landlords, civil servants, and practitioners of modern learned professions under British rule. They approximate Maharashtrian Brahmins in social organization and religion. They imitate Brahman clan (gotra) names, but without claiming descent from Vedic sages. They prohibit marriage among sapindas (see INDIAN LAW: Hindu Law: Marriage) and until recently forbade the remarriage of widows. They employ Brahman priests fully and take the sacred thread (see HINDUISM: Everyday Religious Life). See also CASTE (INDIAN).

See R. E. Enthoven, *The Tribes and Castes of Bombay*, vol. 3 (1922); R. V. Russell, *The Tribes and Castes of the Central Provinces of India*, vol. 3 (1916).

PRACTICE AND PROCEDURE. Law is sometimes said to consist of two parts, substantive law and adjective law. The former is concerned with the definition of legal rights, the latter with the modes of enforcing them. This article discusses the machinery of the courts and the methods by which both the state and the individual (the latter including societies, whether incor-

porated or not) enforce their rights in the several courts. For the composition and powers of these courts, see COURT. Procedure is a self-explanatory term; practice may be defined as the rules of procedure, these being one part of the system of adjective law. The other principal part is the law of evidence (q.v.); i.e., the rules governing proof of the facts by means of which a party seeks to establish his claims or to rebut those of his opponents.

Emphasis in this article is placed on practice and procedure in the English courts; practice and procedure in United States federal and most state courts and in the Canadian courts derive from the same source as in England, namely, the rules of common law and equity. Scotland has different rules and different nomenclature from England, because the main roots of the Scots system is Roman law. (See SCOTS LAW.) The main principles of Anglo-American practice and procedure will be discussed as follows:

I. England

A. Criminal Prosecution

1. The Prosecutor
2. Indictable Offenses and Summary Offenses
3. Magistrates' Court Proceedings
4. Trial of Indictable Offenses by Higher Courts
5. Appeals

B. Civil Procedure

1. Protection and Enforcement of Legal Rights
2. High Court Procedure
3. Magistrates' Court Procedure

II. United States

1. History of the Code Reform
2. Federal Rules of Civil Procedure
3. Status of Pleading Systems
4. Course of Proceedings in a Civil Action
5. Criminal Procedure

III. Canada

1. Selection of the Forum
2. Beginning Actions and Pretrial Procedure
3. Trials
4. Enforcement of Judgment

I. ENGLAND

It is convenient to distinguish at the outset between, on the one hand, the rules applicable to proceedings the object of which is to maintain public order or to punish breaches of it; and, on the other hand, the rules applicable to proceedings whose object is to establish or enforce civil rights, whether public or private. Therefore the two following sections deal consecutively with procedure in criminal prosecutions and civil procedure.

A. CRIMINAL PROSECUTION

1. The Prosecutor.—Prosecutions are undertaken in the name of the crown, but they may be started by private individuals or by corporate bodies (e.g., British Railways, which has to initiate a vast number of prosecutions for such offenses as pilfering on the railways or traveling without a ticket, apart from more serious offenses). There are, however, certain offenses for which prosecutions may not be instituted without the authority of the attorney general, such as incest, except where the director of public prosecutions has instituted the proceedings, and offenses under the Official Secrets Act of 1911.

The director of public prosecutions has particular duties in relation to a number of offenses. He must institute, undertake, or carry on criminal proceedings in any case involving the death penalty; in any case, referred to him by a government department, in which he considers that criminal proceedings should be instituted; and in any case which appears to him to be of importance or difficulty or otherwise to require his intervention. Chief officers of police have to report to the director a number of offenses allegedly committed within their districts. These include incest and other serious sexual offenses, forgery, coinage offenses, sedition, conspiracies to pervert the course of justice, corruption by a private official, obscene or indecent libels, and offenses against the Extrajurisdiction Act of 1870 and the Fugitive Offenders Act (1881). The director's duties in relation to special classes of cases are not, however, exclusive; i.e., there is no question of others being forbidden to prosecute if he decides not to. A private individual may prosecute in cases other than those in which prosecution may be initiated only on the order of a judge of the Queen's Bench Division, on the

authority of the attorney general or on that of the director of public prosecutions, if the director does not choose to prosecute; as, for example, in a murder charge.

However, while the director of public prosecutions undertakes the more difficult and important cases and private prosecutors intervene on a limited number of occasions, most charges are preferred and most prosecutions are undertaken by the police. Any constable may prosecute, but in practice the authority of a superior officer is obtained before proceedings are undertaken in a case of any seriousness.

2. Indictable Offenses and Summary Offenses.—Before considering further the procedure in criminal trials, it is necessary to distinguish between indictable offenses and summary offenses, because the procedure differs accordingly. An indictment is a written accusation signed by the clerk of a court of assize or quarter sessions charging a person or persons accused of an indictable offense with such an offense; the indictment may, by means of separate counts, charge him or them with more than one offense. An indictable offense, if committed by an adult, is triable on indictment, while summary offenses are triable only summarily (*i.e.*, by magistrates sitting in a court of petty sessions without a jury).

In effect, indictable offenses are those offenses which are tried by a jury in a court of assize or quarter sessions. From this point of view, there are three classes of offense: (1) those triable only on indictment; (2) those triable only summarily (*i.e.*, by magistrates' courts without a jury); and (3) those triable either on indictment or summarily, at the option either of the prosecution or of the accused. For example, a charge of causing death by dangerous driving is triable on indictment only; a charge of driving without due care and attention can be tried only summarily; and a charge of simple dangerous driving (*i.e.*, without causing death) or of driving under the influence of drink or drugs can be tried either way, at the choice of prosecution or defense.

The defendant has a right to trial by jury (*i.e.*, by indictment) if the offense (unless it is an assault or comes under s. 1 of the Vagrancy Act, 1898) carries a maximum sentence of more than three months' imprisonment. The right of a prosecutor to demand that the accused be tried by jury depends on a number of enactments dealing with specific offenses. The prosecutor will normally claim trial by jury where he considers that the offense merits a severer penalty than a magistrates' court is competent to impose (although petty sessions have the power to send an offender convicted before them to quarter sessions for sentence); whereas a defendant will choose to be tried by jury if he considers that he has a better chance of being acquitted by a jury than by magistrates.

Most criminal cases tried in England and Wales are tried by magistrates' courts. In 1962, for example, 29,570 persons were found guilty of indictable offenses by the higher courts (*i.e.*, assizes, crown courts, and quarter sessions), whereas 174,205 persons were found guilty of such offenses by magistrates' courts. When to this total is added the figure of 1,062,821 persons found guilty of nonindictable offenses, it will clearly be seen how high is the proportion of criminal business done by magistrates' courts. Criminal proceedings in such courts are initiated by information, as distinct from civil proceedings, which are initiated by complaint. An information, apart from any statutory requirement to the contrary, need not be in writing, but is generally required by the courts to be so; but where a warrant has been issued for an arrest, the information must be in writing and substantiated by oath. A warrant may be issued only where the offense charged is an indictable one (for the question of arrest, see below).

3. Magistrates' Court Proceedings.—*By Way of Information.*—As has been said above, most proceedings in criminal cases are by way of information, and for the majority even of indictable offenses this procedure is followed because the cases are decided by magistrates' courts rather than by the higher courts.

The first step in the judicial process is the laying of an information before a justice of the peace, who has to decide whether the matter is within the scope of his jurisdiction (*e.g.*, whether the offense was committed within the county or borough for which

he is a justice) and whether it is otherwise proper for a prosecution to proceed. If he decides these questions in the affirmative, he has next to decide whether to issue the defendant a summons to appear before the court or whether to issue a warrant for his arrest. He will not as a rule issue a warrant in the first place unless the charge is serious or unless a summons is likely to be disobeyed; but he has power to issue a warrant in respect of any indictable offense. A warrant cannot be issued in respect of an offense which is triable only summarily; and before it can be issued at all the information must be put into writing and substantiated on oath.

The summons must state briefly the substance of the charge and must be signed by the justice issuing it; it must state the time and place at which the defendant must appear to answer the charge. A single summons may be issued in respect of several informations. A summons may be served in person, left with some person at the defendant's last known address, or sent there by registered post. The Magistrates' Courts Act, 1952 (s. 3), provides for the jurisdiction of justices where offenses have been committed on jurisdictional boundaries or have been started in one jurisdiction and finished in another. Such offenses may be treated as having been committed in either jurisdiction.

When the case comes for trial the court, if the accused appears, states to him the substance of the information and asks him whether he pleads guilty or not guilty. A procedure has come into existence whereby, on charges that are triable only summarily, the accused can at his option plead guilty in writing, setting out any grounds of mitigation that there may be; and the court may thereupon convict and sentence him. Equally, a defendant who is absent may plead guilty through solicitor or counsel representing him, and the court may thereupon proceed to pass sentence. If the accused does not appear, and it is established that he has had reasonable notice of the trial (or, on an adjourned trial, that he has previously failed to appear), the court can decide to hear the case in his absence; or, if the information has been substantiated on oath and the offense is considered to be of sufficient gravity to justify it, can issue a warrant for his arrest.

If the information charges the defendant with an offense that is triable either summarily or on indictment, the mode of trial to be selected depends on a number of factors. If the accused has a right of trial by jury, he must be informed of his right before he is called on to plead guilty or not guilty. If he should not have this right, or should he, having it, decide not to exercise it, the procedure to be followed depends mainly on the course adopted by the prosecution. If the prosecution applies to have the case tried summarily, the court may decide to grant the application (though, before doing so, if the offense is within the jurisdiction of quarter sessions, the magistrates should inform the accused that, if he is convicted and they are of opinion that he merits a more severe punishment than petty sessions can impose, they may send him to quarter sessions for punishment). This gives him a further opportunity to choose trial by jury. Thus, in effect, it is as a rule only at the option of both prosecutor and defendant that an accused, charged with an offense triable either summarily or on indictment, will be tried summarily. An important exception is made if the accused is a child under 14. Such a child will be tried summarily unless he is charged with homicide; or, if he is accused jointly with a person who has attained the age of 14, the court, if it considers this necessary in the interests of justice, may commit them both for trial. The court also has power to deal summarily with any offense other than homicide with which an accused under 17 is charged, though if he is between 14 and 17 it is not bound to do so.

Summary Trial.—Once it is decided that the trial shall be a summary one, the procedure is the same whatever the offense. The prosecutor calls his witnesses, addressing the magistrates if he considers it necessary; and the defense does likewise, both prosecutor and defense being limited as a rule to one speech. The court is composed either of a minimum of two lay justices, or of one stipendiary magistrate where provision for such exists. If, as in the vast majority of magistrates' courts, the magistrates are laymen, their clerk (who is normally, though not necessarily, a solicitor—he may be a barrister, or even have no legal qualification, though

this last is unusual) gives them such guidance as they may require on questions of law. He should not, however, retire with them to form their conclusions on the questions of fact which they have to decide. The chairman, finally, announces the decision of the court and the sentence it has decided to impose.

The proceedings are in open court. There are, however, some important differences for the trial of an accused under 17 years of age. He is tried by a juvenile court whose members are drawn from a special panel of justices. The proceedings are in private, the sittings are in a room apart from the adult court where other cases are being tried on the same day, and the press is not allowed to publish reports.

4. Trial of Indictable Offenses by Higher Courts.—*Pretrial Procedure.*—When a trial is not to proceed summarily, the functions of the justices are to hear and record the evidence presented by the prosecution, and by the defense, if any; and either to commit the accused for trial at one of the higher courts, if they consider that there is a case for him to answer, or else to discharge him. When sitting for this purpose the justices are described as examining justices (these functions can be discharged by a single justice). Examining justices are not bound to sit in open court, although in fact they generally do so. They have power to prohibit the publication of any report of their proceedings if they consider that such publication is likely to prejudice the fair trial of the accused. Each witness has to sign the record taken of his evidence.

The court has to bind each witness (other than the accused himself and any witness to his character only) to attend and give evidence before the court by which the accused is to be tried; and it also has to bind the prosecutor by a recognizance to prosecute before that court.

When it appears to the court that the attendance of a given witness at the trial is not required, either because of some statement made by the accused or because the witness's evidence is merely formal, the court may bind him over to attend the trial conditionally, if he has not already been bound over; or direct that he shall be treated as having been so bound over, if he has already been bound over. The effect is that it is not necessary for the witness to attend the trial unless the court requires him to do so, and that at the trial his evidence may be read instead of being given by himself in person.

If any witness refuses to enter into a recognizance, the court may commit him into custody until he does so enter, or, if he continues to refuse, until the trial. He must be released if the court decides to discharge the accused.

If the court decides to commit the accused for trial, it may either commit him into custody or grant him bail; in other words, allow him to be free, subject to giving such recognizances as the court may require for his appearance at the trial. Committal is normally either to the next quarter sessions (if the charge is within the jurisdiction of quarter sessions) or to the next assizes. There are, however, provisions authorizing the court to commit to assizes if the gravity of the case warrants it, even if the charge is technically within the competence of quarter sessions; and also to commit to quarter sessions or assizes other than the local ones on grounds either of hardship or of general convenience. Having started inquiries into any information relating to an offense that is triable either summarily or on indictment, the justices may, if they think proper, try the case summarily on application made either by the prosecutor or by the accused.

Trial Procedure.—The courts to which magistrates may commit defendants for the trial of indictable offenses, *i.e.*, in general, assizes (to which judges come on circuit) and quarter sessions (*see* QUARTER SESSIONS, COURT OF), include certain courts where the trial of criminal cases is to some extent centralized, such as the Central Criminal Court at the Old Bailey in London, and the Crown Court in Manchester, where a judge of the High Court of Justice presides over the most important trials. The chairman's part in trials at quarter sessions is precisely the same as that of the recorder or as that of the judge at an assize court except that, when the defendant is convicted, the chairman and the justices sitting with him will confer as to the sentence.

Trial in all these courts is conducted in the same way. Its essential feature is that it is trial by jury. A judge conducts the trial, gives any rulings on law that are necessary in the course of it, and passes sentence (after consultation with lay justices at county sessions) on any convicted prisoner; but the jury, as judges of fact, agree on the verdict, which has to be unanimous, on each count of the indictment. The trial usually begins with the clerk of the court reading each count and asking each accused person to plead either guilty or not guilty to it. If there is any objection to the form of the indictment, or it is sought to make any amendment thereto, this matter must be disposed of by the court before the prisoner is called upon to plead. If there is more than one prisoner, and all or some of the pleas are of not guilty, it will be decided whether the prisoners are to be tried separately or together after the taking of their pleas. If the pleas are all of guilty, counsel for the prosecution outlines the prosecution case and calls evidence—normally from the police officer in charge of the case—as to the antecedents of the accused. The accused or his counsel calls any evidence as to the accused's previous good character or as to the difficulties of his situation; and addresses the court, as is said, "in mitigation"—that is, in order to persuade the court to take the most lenient view possible of the offense. Finally, if the offense charged is a felony, the clerk calls on the accused to say why the court should not now proceed to pass sentence on him; and thereafter, when the prisoner has said anything that he wishes, the court passes sentence. The same procedure is followed after a verdict of guilty as after a plea of guilty.

When the court proceeds to trial after a plea of not guilty, the clerk calls on each member of the jury by name (either prosecution or defense may object to any individual juror; *see* JURY). After a jury of 12 has been empaneled without objection, the clerk administers an oath to the jurors collectively that they will try the issues according to the evidence, and then reads to them the contents of the indictment. Prosecuting counsel next addresses the jury, outlining the nature of the charge or charges and the evidence which he intends to call in proof. At the conclusion of his speech he calls his witnesses and examines them; the defense then cross-examines them so far as is considered necessary or useful; and the prosecutor thereafter examines them again, if he deems it expedient, on any matters raised in the course of cross-examination. When he has finished reexamining his last witness, he says to the judge, "That is the case for the prosecution" or words to that effect.

At this stage (if the defense considers that there are gaps in the prosecution evidence which justify such a course), the defense may submit to the judge that there is no case for the jury to consider. Should the judge accept this submission in relation to any of the counts, he directs the jury to bring in a verdict of not guilty in relation to them. If the verdict or verdicts so reached should dispose of the whole indictment, the prisoner is discharged and the trial is at an end. Otherwise, or if there is not a submission of no case, the defense will deploy its own case.

The course this takes will depend on the nature of the defense evidence; if the defense calls no evidence, counsel (or the accused himself, if, as seldom happens with the development of the legal aid system, he is unrepresented) will forthwith address the jury. If there is only one defense witness, or the evidence is short and simple, the defense testimony will be called for at once. If the defense case involves more than one witness, and counsel deems this course to be warranted, he will address the jury in order to explain the general nature of the defense before witnesses are called. They will be examined, cross-examined, and reexamined in the same way as the prosecution witnesses. The defendant himself may choose whether to give evidence on oath, or not on oath and without leaving the dock, or to remain silent. If he elects to give evidence on oath, he leaves the dock and testifies, like the other witnesses, from the witness-box. If he does not give evidence on oath, the prosecution may not comment on his not doing so, although the judge may.

At the conclusion of the evidence for the defense, the prosecution may apply to call evidence in rebuttal should any unexpected defense evidence justify this course; the judge will not allow

this except in unusual circumstances. Both prosecution and defense counsel have then the opportunity to address the jury, first the former, then the latter. Finally, the judge sums up, his summing up consisting partly of a legal direction to the jury and partly of a review of the facts in which it is essential that he should put to the jury the defense against each charge. At the conclusion of the summing up the jurors retire to consider their verdict or verdicts. When they return to the court their foreman (whom they have elected) announces the verdicts they have found. If these are all not guilty, the prisoner is discharged. Otherwise, the same procedure is followed as that described above as if the accused had pleaded guilty.

5. Appeals.—Appeals in criminal cases can be classified under three heads: (1) appeals on questions of fact, from magistrates' courts to quarter sessions; (2) appeals, whether on questions of fact or of law, from the higher courts (*i.e.*, assizes and quarter sessions) to the Court of Criminal Appeal (*see* CRIMINAL APPEAL, COURT OF), and, ultimately, with leave, to the House of Lords; (3) appeals, on questions of law only, to the divisional courts from magistrates' courts or from quarter sessions (when sitting in an appellate capacity only; appeals from quarter sessions exercising their original jurisdiction go to the Court of Criminal Appeal, as stated above).

Appeals in the first two of these three categories can be initiated by the defendant only. Appeals in the third category can be initiated on behalf of either defendant or prosecutor; and the divisional court, where a prosecutor's appeal is successful, may either send the case back to the lower court with a direction to convict or may order a rehearing.

Appeals from Magistrates' Courts to Quarter Sessions.—Notice of appeal has to be given within 14 days, although this time can be, and often is, extended by leave of quarter sessions. Appeal may be against either conviction or sentence. The procedure is by way of rehearing, the respondent opening his case first and calling his witnesses (if the appeal is against conviction), just as in the lower court, and the appellant following. Speeches are limited to one each, unless some question of law is involved. Fresh evidence (*i.e.*, evidence not called in the court below) may be called on appeal.

Appeals from Higher Courts to Court of Criminal Appeal.—An appeal lies as of right on a question of law, but by leave either of the court of first instance or of the Court of Criminal Appeal on a question of fact. A notice of appeal setting out the grounds of appeal has to be submitted to the court within 14 days (except on capital charges, where there is no time limit). When a notice is given (which may be with an application for extension of time), a transcript of the shorthand note of the evidence, of the summing up, and of any rulings on law that the judge may have made, is submitted with the notice to one of the judges of the Court of Criminal Appeal, who may himself grant the application for leave to appeal. If he does, the court (of three judges, or, in an exceptionally important or difficult appeal, five) then proceeds to hear the appeal. If he does not, the court may hear the application and grant it, often treating this as though it were the appeal itself, which the court may allow or dismiss—it may, of course, simply refuse the application for leave to appeal. An appeal may be against conviction or sentence or both. When it is against sentence, the Court of Criminal Appeal may increase the sentence; and it sometimes grants an application for leave to appeal against sentence in order to increase it. When the court dismisses an appeal against conviction it (or the House of Lords) may certify that there is a point of law of exceptional public importance, and it (or the House of Lords) may then grant leave to appeal to the House of Lords. The certificate does not of itself entitle the appellant to leave to appeal to the House of Lords, but is a necessary prerequisite of such leave.

The appeal is by way of rehearing; but this normally consists of the reading of relevant parts of the transcript by the appellant's counsel and argument thereon. The respondent's counsel follows, and the appellant's counsel has a right of reply. Evidence not used in the court below is in practice only admitted by the appeal court when it has not been available at the trial; but the appeal court is

empowered to hear oral evidence. After long controversy, the court was authorized to order a new trial instead of directing the entry of a judgment and verdict of acquittal; but it is still permitted to deal finally with a matter. A retrial may take place only in respect of (1) the offense of which the appellant was convicted at the original trial and in respect of which his appeal is allowed; (2) any offense of which he could have been convicted at the original trial on an indictment for that offense (*e.g.*, attempted housebreaking instead of housebreaking); (3) an offense charged in an alternative count of the indictment on which the jury was discharged from giving a verdict at the trial.

Appeals to the Divisional Court.—These are by way of case stated; that is, the party intending to appeal asks the chairman of the magistrates' court or of the court of quarter sessions to prepare a statement of the relevant facts and of the grounds of the court's decision. In practice, the appellant will generally prepare the case through his legal advisers and ask the chairman to agree to it and sign it. If the court refuses to state a case, the appellant may apply to the divisional court for an order of mandamus directing the lower court to state a case. Appeal lies from the divisional court, with leave, to the House of Lords.

See CRIMINAL LAW.

B. CIVIL PROCEDURE

1. Protection and Enforcement of Legal Rights.—Criminal proceedings have been considered above; *i.e.*, those in which some breach, or alleged breach, of public order is involved, whether it be a crime of violence or of dishonesty or both; or whether it be some offense creating conditions of physical danger or inconvenience to the public (as do motoring offenses, or even such comparatively trivial breaches of public order as riding a pedal cycle without lights or stopping a railway train by pulling the communication cord without good reason).

The procedure now to be discussed concerns cases in which the rights of an individual (or of a corporation, such as a county council or a limited company) are invaded by some act or omission on the part of another; and in which action is taken in the courts to redress the matter by (1) obtaining compensation (damages); (2) restraining repetition of unlawful conduct by means of an injunction (*q.v.*) addressed by the court to the wrongdoer; (3) commanding performance of a specific action where a party to a contract, for example, is failing to carry out his part of the bargain. There are cases, too, in which a party to a contract seeks to ascertain or clarify his legal rights, when he may seek from the courts a declaration or rectification of the written contract.

There is a class of cases where a party seeks from the High Court of Justice (*q.v.*), one of whose essential attributes is unlimited jurisdiction, the protection or enforcement of his rights either against an inferior court (in the sense of a court of limited jurisdiction; *e.g.*, a county court or a magistrates' court); or against a government department or a local authority which, for the purposes of particular legislation (such as the Town and Country Planning acts), has judicial or quasi-judicial powers. The High Court, although it is only a court of appeal from such courts when so established by statute, has a general, supervisory jurisdiction to see that they comply with and keep within the law. It carries out these duties by three types of order: mandamus, certiorari, and prohibition. An example of mandamus has been given above, where a party seeks an order to a magistrates' court that it shall state a case to enable the High Court to consider the legal correctness of its decision.

An order of certiorari is made where the award of a judicial or quasi-judicial tribunal either constitutes an excess of its jurisdiction or contains an error on its face. An order of prohibition forbids an inferior court or an authority with judicial or quasi-judicial powers to act outside its lawful scope—as when a tribunal has evidenced its intention of hearing a cause outside its jurisdiction (*see* ABATEMENT).

Other cases which come under this head are matrimonial causes. The Probate, Divorce, and Admiralty Division of the High Court alone has jurisdiction to grant decrees of divorce or nullity of marriage and of judicial separation. It, too, alone has unlimited power

ers to order a divorced or separated person to maintain his spouse or former spouse. (But the magistrates' courts also exercise matrimonial jurisdiction over a very wide field; they can, for example, order a husband to maintain his wife and children.)

The proving of wills (*see PROBATE*) and the granting of letters of administration where wills cannot be found, so that the estates of deceased persons can be distributed, are other functions of the courts. This jurisdiction inheres in the Probate, Divorce, and Admiralty Division of the High Court, but the county courts have powers to deal with smaller estates. Much of this work is non-contentious.

Parallel with the division of jurisdiction over matrimonial causes between the Probate Division of the High Court and the magistrates' courts is that among the Chancery Division of the High Court, the county courts, and the magistrates' courts over the guardianship of infants. The Chancery Division and the magistrates' courts likewise divide between them provision for claims by mothers against putative fathers for the maintenance of illegitimate children; and jurisdiction in relation to adoption orders is again divided among the Chancery Division, the county courts, and the magistrates' courts.

These categories of types of proceedings that can be brought in the civil courts are by no means exhaustive. No mention has been made, for example, of the Restrictive Practices Court, with its extremely important jurisdiction under the Restrictive Trade Practices Act, 1956, and the Resale Prices Act (1964). They perhaps indicate sufficiently the field of work covered by the civil courts.

2. High Court Procedure.—Initiation of an Action.—There are four means of starting proceedings in the High Court: by writ, by originating summons, by originating motion, and by petition. Each of these has its own uses, although at some points they overlap. The writ has to be used in claims based on tort (*i.e.*, on civil wrong—other than trespass to land, fraud, or breach of duty, whether contractual, statutory, or otherwise) where the damages claimed are in respect of the death of or injury to any person or in respect of damage to property. Actions for trespass to land may be begun either by writ or by originating summons; and probate actions and certain admiralty actions also may be initiated by writ. An originating summons must be used where an application (other than in pending proceedings) is made under any act, except where some other procedure is expressly required or authorized. Except where otherwise specifically required, proceedings may be begun either by writ or by originating summons, as the plaintiff (*i.e.*, the party initiating the proceedings) considers appropriate. Proceedings in which the principal issue is likely to be the construction of an act of Parliament or of some document, or in which there is unlikely to be any substantial dispute of fact, are appropriate for the use of originating summons unless the plaintiff intends to apply for summary judgment. Proceedings may only be begun by motion or petition when this is expressly authorized by the rules of the Supreme Court. An example of procedure by motion is the apportionment of salvage in the Admiralty Division. The petition is best known for its use in matrimonial proceedings, but it is also used in the Chancery Division in certain types of company and bankruptcy proceedings.

Proceedings may be begun and carried on by the plaintiff either in person or through his solicitor.

Preparation of an Action for Trial.—The rules of the Supreme Court of Judicature govern procedure. They are framed by the Rules Committee and cannot take effect until laid before Parliament. These rules are not here analyzed or even summarized; but a general picture is given, seen in its most complete and perhaps most complex form in the action started by writ. The issue of a writ sets in motion a lengthy but logical sequence of steps that have to be taken if each party to the action contests it to the stage at which it is tried. These steps have each to be completed within a certain time; what these times are can be ascertained by reference to the rules themselves. In each case, the times allowed can be extended either by consent of the parties or by leave of the court.

Writs and Endorsements.—The writ itself consists of a direction from the sovereign to the defendant which, after setting out

the names of the parties, commands the defendant to enter an appearance within eight days of its service, and warns him that in default of his doing so the plaintiff may proceed and that judgment may be given against him (the defendant) in his absence. Before the writ is issued it has to be endorsed with a statement of the nature of the plaintiff's claim. This may be either a general endorsement, as, for example, "The plaintiff's claim is for damages for breach of contract"; or a so-called special endorsement, which under the subheading of "statement of claim," sets out in more detail what is the contract alleged and how the defendant is said to be in breach. It is also open to the plaintiff, if the writ is endorsed generally and not specially, to deliver the statement of claim at the same time as he serves the writ. The writ must in either event be endorsed with the name and address of the plaintiff or of any solicitor serving it on his behalf, and with a statement showing that it has been served, together with the date of service. Various methods of serving the writ are prescribed, but the ordinary method is by personal service on the defendant, or, if the latter has so authorized, upon his solicitor. The next step is incumbent upon the defendant: namely, to enter an appearance, which can be done by either delivering it or posting it to the Central Office of the Royal Courts of Justice. After an appearance has been entered by or on behalf of the defendant, the plaintiff, if he has not already done so, has to deliver his statement of claim.

Applications for Summary Judgment.—If the writ is specially endorsed, or if the statement of claim is delivered at the same time as the writ is served and the claim is for debt, for liquidated damages (*see DAMAGES*), or for the specific performance of a contract the plaintiff may swear an affidavit to the effect that there is no defense to the action, and apply for summary judgment. This step is taken by means of a summons to appear before one of the masters of the Supreme Court. The masters are subordinate judicial officers who are entrusted, subject to the right of appeal to a judge sitting in chambers (as distinct from open court), with the supervision of all interlocutory and procedural matters and who have certain defined and limited powers to give judgment. An application for summary judgment may be either granted or refused outright, or the master may make some other order directing the trial of the matter. Whatever order he makes is subject to an appeal to the judge in chambers, or, with leave, from the judge to the Court of Appeal: there is, however, no appeal to the Court of Appeal from a decision refusing summary judgment.

The Pleadings.—Should summary judgment not be claimed or be refused, the next step is the delivery of a statement of claim, should this not have been taken already. This should set out the material facts on which the plaintiff bases his claim, though not the evidence by which he intends to prove it. The defendant has in his turn to deliver a statement, called the defense, which in its turn sets out the material facts on which he relies; in default of defense the plaintiff may apply for judgment. The statement of claim and the defense are each called "the pleadings." There may be further pleadings if it cannot be presumed, for example that the plaintiff traverses all matter in the defense, so that there may be a reply, a rejoinder, and even a surrejoinder (though these last two are most exceptional). It is open to either party to apply to strike out his opponent's pleading, or part thereof, on the ground that it discloses no cause of action or of defense, as the case may be, and on certain other grounds; the effect of a successful application of this sort may be to dispose of the matter. It is likewise open to either party to apply for further particulars of his opponent's pleading on the grounds that this does not sufficiently disclose the case he has to meet; and the delivery of further and better particulars may be ordered.

The above is a simple example in which one plaintiff sues one defendant for one cause of action. The rules make provision for the joinder both of parties and of causes of action. Further, if a defendant (1) claims against a person not already a party to the action any contribution or indemnity; (2) claims against such a person any relief or remedy relating to or connected with the original subject-matter of the action, and substantially the same as some relief or remedy claimed by the plaintiff; (3) requires that any question or issue relating to or connected with the orig-

nal subject matter of the action should be determined not only as between himself and the plaintiff but also as between either or both of them and a person not already party to the action; he may issue a notice, called a third party notice, containing both a statement of the nature of the claim made against him, and a statement either of the nature and grounds of the claim made by him or of the questions or issues to be determined. The leave of the court is required for the issue of a third party notice, unless the action is begun by writ and the notice is issued before delivery of the defense. A third party has the same rights against the defendant as the latter has against the plaintiff; and he may bring in a fourth party, and the fourth party a fifth party, and so on.

Discovery and Inspection.—When the process of exchanging pleadings has been concluded and the pleadings, under the rules, are deemed to be closed, the parties normally have to serve on the other parties lists of the relevant documents which are, or have been, in the possession, custody, or power of the former. This process is known as discovery and is followed by inspection.

Summons for Direction.—After either the close of pleadings (or in the actions in which discovery is necessary) after discovery, the plaintiff has to take out what is known as a summons for directions. The object of this, in the words of the rule, is to provide "an occasion for the consideration by the court of the preparations for the trial of the action, so that: (a) all matters which must or can be dealt with on interlocutory applications and have not already been dealt with may so far as possible be dealt with; and (b) such directions may be given as to the future course of the action as appear best adapted to secure the just, expeditious, and economical disposal thereof."

There are certain classes of actions to which the rule as to the summons for directions does not apply—e.g., cases where directions have already been given in an application for summary judgment; actions referred for trial to an official referee (a judge who deals with actions in the High Court involving detailed inquiries into figures); and actions for the infringement of a patent.

The matters to be considered at the hearing of the summons for directions include the place and mode of trial. It must be decided whether there is to be a jury or not, and whether the case is suitable for transfer to a county court, to an official referee, or to the commercial list (where it can be tried, rather more expeditiously, by a judge with special experience of commercial matters). The court (which means for these purposes a master of the Supreme Court) has also to consider whether the writ or any of the pleadings requires amendment; whether in any respects documentary or affidavit evidence should be allowed instead of oral evidence; and whether there should be any limitation of the medical or expert evidence to be called. The court has also to try to secure that the parties make all admissions and all agreements that appear to be reasonable, as to the conduct of the proceedings; and the parties have to try to dispose of all interlocutory business that may be necessary before trial, such as any applications to administer interrogatories (which have to be answered on oath) to any other party to the action.

When the interlocutory business has been disposed of, the plaintiff has to set the action down for trial; and, should he fail to do so within a reasonable time, the defendant may apply to the court for the action to be dismissed for want of prosecution.

The Trial.—At the trial the procedure followed is broadly similar to that in a criminal trial, although there are differences, some of which depend on whether or not there is a jury. The plaintiff (generally, of course, through his counsel) will open his case with an address outlining the issues and the evidence he proposes to call. The defendant may at the conclusion of the plaintiff's evidence submit that it discloses no case; but if he does so he has to stand on his submission—that is, he is precluded from calling evidence in support of his own case. If he does not make such a submission, the defendant will decide whether to make an opening address or not, will call his evidence, and will conclude his case by a speech, to which the plaintiff will reply. If there is a jury, the judge will then sum up to it (probably, if the case is of any complexity, putting to it a number of questions, frequently agreed with counsel for the parties, to which the jury has to give the

answer). If there is no jury, the judge will deliver a judgment setting out his findings on the facts and the legal conclusions he draws from them—announcing, in fact, the result of the action. If damages are claimed in the action, and there is a jury, it decides the amount of the damages, if any; if there is no jury, the judge does so. He also decides and announces his award as to costs; i.e., as to who must pay the costs of the action.

Costs are in the discretion of the judge; but this discretion has to be exercised judicially, and the normal rule is that costs follow the event. The judge will then simply direct that the successful party shall have the costs of the action, and these will then be submitted to a process known as taxation. The matter will be remitted to one of the court officials called taxing masters, who will quantify the amount to be paid by the unsuccessful to the successful party, applying the principle that the latter is entitled to such costs as were reasonably necessary for the prosecution of the action. In practice, the taxing master will generally reduce quite drastically the successful party's bill. His decision is subject to appeal by either party should he err in principle. Different scales of costs are applicable to different classes of action, the most usual scale being known as "party and party," where costs are taken into account from, but not before, the issue of the writ.

If damages have been awarded, and the party against whom they are awarded indicates his intention to appeal, the judge may order (in whole or in part) a stay of execution. The effect of this is that the successful party may not take steps to enforce payment of the damages until after the appeal, or until the time allowed for entering a notice of appeal has expired.

A formal judgment embodying the order of the court has to be prepared and signed.

The procedure outlined above is particularly applicable to actions in the Queen's Bench Division of the High Court. Differences exist, both among kinds of action, especially when started otherwise than by writ, and among divisions of the High Court. Clearly, where the main issue is the construction of a document, the processes of preparing for trial (the chief complexities of which derive from the necessity of submitting and proving, whether orally or by documentary evidence, those facts which are relevant and legally admissible) will need to be less elaborate. Likewise, in the county court, where the subject matter of the action is less weighty than in the High Court (*see COURT*), to apply the identical principles with the same elaboration as in the High Court would be not only uneconomic but in effect a denial of justice if the stakes involved were less financially valuable than in a High Court case. For details of procedure, see *The Annual Practice* (for proceedings in the High Court) and *The County Court Practice* (for proceedings in the county courts).

3. Magistrates' Court Procedure.—Civil proceedings in magistrates' courts are initiated by the making to the court of a complaint, which need not be in writing or on oath, followed by the issue of a summons if the complaint shows that the subject matter is within the jurisdiction of the court. At the hearing the court has to state to the defendant, if he appears, the substance of the complaint, and then to hear the evidence. If the complaint is for an order for the payment of a civil debt or for the variation of any order for periodical payments (or, it would seem, for any order within the court's competence), the court may, with the defendant's consent, make an order without hearing evidence.

Much of the civil jurisdiction of magistrates' courts is concerned with domestic proceedings as defined by the Magistrates' Courts Act, 1952 (s. 56); these include cases under the Guardianship of Infants acts (1886, 1925), and the Summary Jurisdiction (Separation and Maintenance) acts 1895 to 1949, among others. The court for these purposes has to consist of not more than three justices, of whom if possible at least one shall be a man and at least one a woman. The public has no right to be present and the court may order the withdrawal of all those, including the press, who are not directly concerned, during the taking of indecent evidence.

For information on appeals, *see APPEAL; COUNTY COURT; COURT OF APPEAL*. In order to initiate an appeal, a notice of appeal has to be given, setting out the grounds. The appeal is

by way of rehearing, but this is carried out by reading of the transcripts of evidence taken in the lower court; only in exceptional circumstances, when the court is satisfied that important evidence is available that was not available at the hearing at first instance, will leave be given for fresh evidence, oral or documentary, to be heard. For an appeal to the House of Lords, more elaborate documentary preparation is required, and the parties to the appeal have to prepare a detailed statement of their case. An appellate court may order a new trial if that is considered appropriate.

Appeals from magistrates' courts in civil cases are governed by the same procedure as appeals in criminal cases. A case stated to the High Court is considered by a divisional court of the appropriate division; for example, a matrimonial appeal by way of case stated will be heard in the Probate, Divorce, and Admiralty Division, and an appeal under the Guardianship of Infants acts in the Chancery Division.

II. UNITED STATES

Though shorn of many of the trappings of the English tradition, the practice and procedure of all the courts of the United States except those of Louisiana are derived from the English system. But since each state and territory, and the federal government also, has its own system of courts and its own procedure, considerable diversity exists.

In general, the United States courts have benefited from a reform of court procedure similar to that made in England during the 19th century, owing to Jeremy Bentham, Lord Langdale, and others (Bentham's influence in the United States was strong); but the extent of the reform varies among the different jurisdictions. The most far-reaching change was that of the so-called code reform of procedure which was fathered by the code of civil procedure adopted in New York State in 1848; this code was eventually followed in substance in 40 U.S. states and territories and in the federal system. A later reform was that of the Federal Rules of Civil Procedure, adopted in the federal courts in 1938 and copied in many of the states, as noted below.

1. History of the Code Reform.—In 1847 the New York legislature instructed a commission "to provide for the abolition of the present forms of actions and pleadings in cases at common law; for a uniform course of proceeding in all cases . . . and for the abandonment of all Latin and other foreign tongues, so far as . . . practicable, and of any form and proceeding not necessary to ascertain or preserve the rights of the parties" (N.Y. laws, 1847, C. 59, § 8). The commission reported a code which was adopted April 12, 1848. This measure, largely the work of David Dudley Field (*q.v.*), a member of the commission, is often called the "Field Code"; it served as the model for other codes in the United States.

The most fundamental part of the code is its single form of action for all civil cases. The distinctions among various common-law actions and among their forms were abolished; the separation in procedure of equitable from legal relief was abandoned. Prior to adoption of the codes, most American states, following the English example, distinguished, in varying degrees, "legal" and "equitable" actions. These two systems offered distinctive remedies and followed distinctive procedures. Equitable relief includes all remedies which historically were available only in the courts of equity. As a substitute, the codifiers planned a system combining law and equity, with only one form of action—the civil action. This same step was taken in England a generation later in the Judicature Act of 1873; thereby English law may be said to have borrowed from its child.

The full benefits of this reform were not attained in all the states, for many courts clung to the ancient forms of action, holding them to rest upon distinctions fundamental in the law. Furthermore, some courts were hostile toward the attempted union of actions at law and suits in equity. In these cases the history and tradition of the separate systems of law and equity were strong obstacles to a complete amalgamation. It has therefore often been held that the theory of the action, whether legal or equitable, must be pointed out in the pleadings. In fact, however, the difference between law and equity actions is chiefly in the remedy

granted, and this should not be an objection to the single action or the simpler forms of pleading.

Perhaps one obstacle has seemed greatest to the courts in preventing a complete union of law and equity: this is the requirement in all the state constitutions that the right of trial by jury shall remain inviolate. This is construed to mean a preservation of that right substantially as it was when each state's constitution was adopted. As a result, jury trial is a matter of right in cases which would formerly have been actions at law, while in equitable claims no such right exists. Some courts, in protecting the constitutional right, continue to divide all actions into "law actions" and "equity actions." A more convenient rule, and one more in keeping with the code principle, is followed in many states, where the question of the form of trial is not allowed to affect the pleading in advance of the trial. If an issue arises at the trial whether there is a right to jury trial, it is decided by the nature of the issues developed in the pleadings in the light of the historical method of trying such issues.

Another important characteristic of the code is its emphasis upon pleading facts, not evidence or conclusions of law. Fact pleading was substituted for the issue pleading of the common law. This part of the code reform has been comparatively unsuccessful, because no clear line of demarcation exists between statements of fact and statements of law. An additional change wrought by the code was the adoption of the equity principles of greater freedom of joining parties (combining different suits) and of rendering judgments in part for and in part against the various parties, as the justice of the case may require (the "split judgment" of equity).

In spite of the fact that the code reform has not had the same degree of success in all the states, it seems in general to have been in accord with the desires of the people for simpler procedure. Modern plans for further reform are all in the direction of greater simplification of practice through authorized rules of court.

2. Federal Rules of Civil Procedure.—Modern reform plans were embodied in the Federal Rules of Civil Procedure, adopted by the Supreme Court of the United States to regulate the practice in the U.S. district courts. The rules were the culmination of a long struggle carried on by leaders of the bar for reform in the federal system. Traditionally the procedure in these trial courts had been divided, although a single judge sat in both law and equity cases. In equity the practice was uniform in the many district courts under rules laid down by the Supreme Court. But on the law side, as opposed to equity, each district court was supposed to conform to the practice in the courts of the state where it was sitting, subject, however, to a considerable and constantly increasing number of federal statutes dealing with details of procedure.

The resulting hodgepodge led the American Bar Association, from 1912 on, to press with vigour for complete rule-making authority to be given to the Supreme Court, so that a uniform system might be developed. No advance was made, however, for several years because of opposition from U.S. senators convinced of the need of preserving the local practice in their individual states. At length, after the Rule-Making Act of 1934 became law, the Supreme Court appointed an advisory committee of lawyers and law teachers to prepare a draft of rules. The committee consulted many members of the bar and bench and many teachers in the law schools and, after the publication and revision of preliminary drafts, made its final report, which the court accepted in 1937. The set of rules was reported to and lay before Congress for a full session, as then required by statute, and became effective Sept. 16, 1938. The committee remained active, recommending amendments from time to time. Among these were amendments effective March 19, 1948, that made extensive reforms; and another, effective Aug. 1, 1951 (Rule 71A, Condemnation of Property), that added a complete rule governing the taking of property by eminent domain—the power of the federal and state governments to take private property for public use without the owner's consent.

The Supreme Court discharged the original committee in 1951. A statute enacted in 1958 gave the Judicial Conference of the

United States the responsibility of making a continuing study of all federal procedure and recommending additions or amendments to the rules in the interest of simple and effective administration of law. In 1960, at the request of the conference, the chief justice of the United States appointed advisory committees for civil, criminal, admiralty, bankruptcy, and appellate procedures, together with an overall standing and supervising committee on practice and procedure. In 1963 an additional advisory committee to draft rules of evidence was authorized. Thus the continuity of court rule making in the federal system is assured. On recommendation of these committees, certain minor amendments of the civil rules were adopted effective July 19, 1961, and a more extensive series of amendments was adopted effective July 1, 1963. Further amendments of the civil rules and amendments of other systems of procedure within the rule-making power were under study.

The federal system of procedure, as regulated by rules of the court made in this way, became a model for reform in most of the states. Those which adopted the federal system are noted below; but hardly one of them has not been affected by the reform in some degree or at least had its bar fired with zeal for far-reaching improvement. The system employs all the best features of English and U.S. state practice acts or codes, and it is generally regarded as ensuring, to a large extent, simple, flexible, and effective court administration. Notable features include a simple and generalized statement of claim and the various devices of discovery and pretrial procedure noted below.

3. Status of Pleading Systems.—The states are often classified as "code" or "non-code," depending on whether or not they adopted the Field Code established in New York in 1848. The lines of distinction, however, became blurred, particularly after 1938 when the federal rules began to be felt. By that time code pleading had been adopted in the following 31 jurisdictions: Alaska, Arizona, Arkansas, California, Colorado, Connecticut, Illinois, Indiana, Iowa, Idaho, Kansas, Kentucky, Minnesota, Missouri, Montana, Nebraska, Nevada, New Mexico, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Puerto Rico, South Carolina, South Dakota, Utah, Washington, Wyoming, and Wisconsin. The adoption of the federal rules brought into this group all the vast federal system, with its 86 district or trial courts and the courts of the District of Columbia, the Canal Zone, Guam, and the Virgin Islands. And the spread of the federal rules to the states, while occurring for the most part in jurisdictions already having code pleading, brought into this group certain other states, notably Maine, New Jersey, and West Virginia. In nearly all of these jurisdictions the law and equity procedures have been fully merged, though in Arkansas, Iowa, and Oregon a formal distinction, and in Illinois a formal labeling, of actions at law and suits in equity are maintained in the same court.

In the mid-1960s the following jurisdictions had fully adopted the federal rules: Alaska, Arizona, Colorado, Delaware (separately for the chancery and law courts), District of Columbia, Hawaii, Idaho, Kansas, Kentucky, Maine, Minnesota, Missouri, Montana, Nevada, New Jersey, New Mexico, North Dakota, Puerto Rico, Utah, Washington, West Virginia, and Wyoming. Furthermore, the federal rules have been followed extensively, although not completely, in revisions of practice in Florida, Iowa, Louisiana, Michigan, New York, and Texas. Also, specific sections or separate rules have been adopted in Alabama, Arkansas, California, Connecticut, Georgia, Illinois, Louisiana, Maryland, Nebraska, New York, Ohio, Pennsylvania, South Dakota, Texas, and Vermont. Hardly a jurisdiction, however, remains unaffected; thus the important Rule 16 for pretrial conferences is universal. Only one state has turned backward; in Nebraska the rules were adopted in 1943, only to be repealed at once by the state legislature.

With respect to the non-code states, now few in number, the old classification into "quasi-code" and "common-law" jurisdictions based on the nearness of approach to code pleading is no longer useful. The practice in states such as Georgia, Massachusetts, New Hampshire, and Virginia is relatively simple and uncomplicated. There is less trace of the modern approach in Mississippi, Rhode Island, and Tennessee, although even these can hardly be termed "common-law" jurisdictions, since the an-

cient practice has been improved in many ways, as by breaking down the old distinctions between law and equity. It is true, however, that the surface diversity among U.S. jurisdictions is accentuated by the fact that an attorney of one state cannot appear as counsel in the courts of another except by special permission of the court for an individual occasion. Underneath, however, is a substantial similarity of objective which could be more easily and fully achieved by uniform rules. Adoption of the federal rules by additional states is a desirable trend toward such uniformity.

4. Course of Proceedings in a Civil Action.—Notice to the defendant at the institution of suit and an opportunity to present his side of the case are essential to the U.S. system of justice. In many of the states the traditional practice is followed of issuing a writ in the name of the state directing the sheriff to make the summons to a defendant to appear in court to answer a suit against him. In others, however, a simple written summons to appear, signed by the plaintiff or his attorney, is used instead; it is served upon the defendant by anyone not a party to the suit—usually by a clerk of the plaintiff's attorney. Even in these jurisdictions, however, when the plaintiff claims some extraordinary or provisional remedy, such as attachment of the defendant's property, arrest of the defendant, or an injunction, notice is given in the form of a court order served by some public officer, such as the sheriff.

Proper service of the summons is essential; unless the defendant is legally notified of the action, no jurisdiction is acquired over his person. Moreover, the action has to be brought to the proper court, the one that has jurisdiction over the subject matter.

Next come the pleadings, the first step being the filing by the plaintiff or his attorney of his complaint or petition. This contains the names of the parties and the court, a statement of the facts making up the plaintiff's cause of action, and a demand for the judgment to which he thinks he is entitled. The complaint is served upon the defendant with the summons, or after the parties are in court, or else is supplied to the defendant by the court clerk.

If the defendant desires to defend, his first move is to enter an appearance, which may be done, without his presence in court, by a written notice of appearance by his attorney or by filing an answer to the complaint. By demurring, the defendant may question the legal sufficiency of the complaint—he asserts that the law provides no remedy for the factual situation stated in the complaint. Where demurring does not exist, as in Illinois and New York, he moves for judgment and thus raises the same issue. In the defendant's answer he may deny the plaintiff's allegations; alternatively, he may admit them and allege new matter in his defense or as a basis for a counterclaim against the plaintiff. To this the plaintiff under most codes may file a reply. At this stage the pleadings are generally required to come to an end. The actual trial follows, with the production of evidence by the parties, followed by the verdict, if a jury is present, and culminating in judgment. If the defeated party so desires he may then take an appeal to some appellate tribunal. (See APPEAL.) When the judgment is finally effective—it can be stayed in many cases by an appeal—extensive proceedings are available to secure its enforcement.

The federal system is substantially the same, but with some change of emphasis from formal pleadings of fact to short and succinct statements of claim or defense, ending with the answer or with a reply to a counterclaim. The demurrer has been abolished, and objections may be presented either by answer or by a motion, including a motion for summary judgment, supported by affidavits or depositions on the merits. Stress is placed on reaching the merits quickly. Hence, so that each party may be thoroughly informed of all elements of the case at once and may thus be in a position to prepare his case completely in advance of trial, there is an extensive system of discovery by the taking of depositions, generally by witnesses; by submission of interrogatories (written questions to witnesses or parties to the suit); by requests for admissions (formal statements of relevant facts); and by the production of documents, and so on. Pretrial conferences, which are optional, are widely used. Their object is to settle the issues (the

points affirmed by one side and denied by the other) and to dispense with formalities of proof of detail. They add to the sense of full preparation for trial and often facilitate settlements out of court. There is practically complete freedom of joinder of actions, both of parties and of suits, as well as of counterclaims. New parties may be summoned to answer claims developed in the case. This system is rounded out by provisions governing trials; these include waiver of jury trial by failure to ask for it within a set time and the simplifying of appeals.

The procedure described is that followed in the trial courts of general jurisdiction, usually but not always called district courts. In the states, there are usually other courts, with limited jurisdiction, inferior to the trial courts. These are known by such names as county court, municipal court, justice of the peace court, small claims court, conciliation court, and the like. Even within a single state, there frequently is a bewildering hodgepodge of these, and their procedures are as varied as the courts. Commonly the defeated litigant in a minor court may have his case tried again in the district court, but this depends on the state and on the nature and size of the claim.

A movement looking to further reform, supported by the American Bar Association, advocates improved court structure and administration. The main feature would be a unified court which would sit in various divisions as required. The chief justice, assisted by an administrative director, would supervise the system and there would be centralized administrative responsibility along businesslike lines. The movement for an integrated court—indeed the whole stress upon better administration of the courts—promises to be the outstanding trend of law reform in the decade commencing in the mid-1960s; in about three-fourths of the states there are responsible movements in the profession, the bar associations, and the legislature toward this end. Outstanding reforms have been achieved in Connecticut (P.A. 1959, C. 28), New Jersey (Const. 1947, Art. 6), Puerto Rico (Judiciary Act, 1952), and Wisconsin (Sess. Laws 1959, C. 315).

5. Criminal Procedure.—Here again the English practice is the source. For capital crimes and many other serious offenses, indictment by a grand jury is still an essential step in a criminal prosecution in many jurisdictions. This body varies in number in different jurisdictions but is usually made up of not less than 12 and not more than 23 persons. The indictment is usually prepared beforehand by the prosecutor and is given to the grand jury for its consideration. A majority of this body must concur in presenting an indictment, which then serves at the trial as the prosecution's complaint. The grand jury may also act upon its own knowledge, upon an information (similar to an indictment) of the prosecutor, or upon a complaint made under oath by a private person before a committing magistrate (one who has authority to conduct preliminary hearings in the case of serious crimes).

A number of technical rules apply to the indictment, making criminal procedure very rigid. Thus, in many jurisdictions, unless the indictment describes the offense with great detail, including its time and place of occurrence and the accused's name, it may be quashed. Authorities today advocate a procedure requiring only that reasonable notice of the ground of complaint be given the accused. In a considerable number of states an information by the prosecutor has been substituted for the indictment by the grand jury. An information suffices in the federal courts except in offenses punishable by more than one year's imprisonment. Trial by jury is usually a constitutional guarantee except for minor offenses. But in Maryland and Connecticut the accused may choose to be tried without a jury.

The American Law Institute, an organization of judges, lawyers, and law teachers with headquarters in Philadelphia, Pa., recommended an advanced and simplified Model Code of Criminal Procedure (1931), which has been adopted in some states. More lately the Supreme Court reformed its criminal procedure, following the method of drafting first employed for the civil rules. Its Advisory Committee on Rules of Criminal Procedure recommended, and the court approved, the Federal Rules of Criminal Procedure; these became effective throughout the federal system March 21, 1946. And, as noted above, a continuing advisory

committee has been organized to recommend changes or additions to the federal rules. Thus there is promise that reform in criminal procedure, which has lagged far behind that occurring in civil procedure, is now at hand.

See ADMIRALTY JURISDICTION; APPEAL; ARBITRATION; COSTS; CRIMINAL LAW; EVIDENCE; JUDGMENTS AND DECREES; PROBATE, SUPREME COURT OF THE UNITED STATES, THE. (C. E. CL.)

III. CANADA

The potential for diversity in procedure in Canadian courts has been enormous. Under the British North America Act, Canada's constitution, 11 legislatures, one of which (Quebec) operates nominally under a civil-law system (see CIVIL LAW), have competence to create systems of courts with their own procedure. Further, procedure in all criminal matters in Canada is controlled by the federal government by virtue of s. 91 (27) of the act. In general, however, there is remarkable uniformity in this branch of the law, and such differences as occur are differences of detail rather than principle.

The principal reason for this has been, no doubt, the extremely close relation of the Canadian legal profession and system to that of England. With a common heritage, as well as the fact that the Privy Council was the final court of appeal for Canada until 1949 it was natural for procedural innovations in Canada to spring from the great reforms that occurred in England in the late 19th century. The English Judicature Act of 1873, by which common-law and equity jurisdictions were fused, has served as a pattern to all Canadian legislatures. (Parenthetically, because of the influence of United Empire Loyalists and other U.S.-trained lawyers in the Maritime Provinces, the merger of equity and common law was completed in Nova Scotia in 1855, many years before this happened in England.) There was, however, powerful opposition to this change in Ontario, a stronghold of conservatism, where originally common law and equity were administered by separate courts using old forms of English procedure. Nevertheless, after several abortive attempts to overcome the opposition of the bar, a Judicature Act modeled on the prevailing English legislation was finally enacted in 1881. Initially, the results of this move were not satisfactory; but slowly, due to modifications of the code in 1888, 1896, and 1913 and more acquaintance with the new procedure by lawyers, the changes became acceptable. Once the battle had been won in Ontario the other provinces followed suit, the last being Prince Edward Island in 1929.

The similarities between procedure in the common-law jurisdictions and in Quebec are especially striking. English influence was felt in Quebec as early as 1763, when at the prompting of the attorney general, Francis Maseres, courts of King's Bench and Common Pleas were established. Maseres, born in London of French Huguenot parents, exerted great influence on the development of law in Quebec and was responsible for much of the English content in Quebec law. Since 1777, when certain aspects of English procedure were introduced by ordinance, most of the basic concepts of procedure in the common-law jurisdictions have been included in Quebec's Code of Civil Procedure.

There is no marked difference in Canada between civil and criminal procedure; the latter is essentially civil procedure where the crown acts as plaintiff and rules of evidence are more strictly enforced. Therefore there has been virtual uniformity in the principles of procedural law, those being the principles of the English law on the subject. The following section deals only with those areas of the law which substantially differ from English practice.

1. Selection of the Forum.—The first procedural problem in any litigation is the choice of the court in which to bring action. In most federal countries this poses serious problems. In Canada the British North America Act provided for a dual system of courts, one for the provinces, which may establish their own courts (s. 92 [14]), and one for the Dominion (s. 101). In practice, however, this has not resulted in federal courts for federal matters and provincial courts for provincial matters. Generally, most matters have been dealt with, at least initially, by the provincial courts that were in existence at the time of confederation. Each

province has a superior court of general jurisdiction from which appeals are taken to the provincial court of appeal. In most cases these are both branches of the province's Supreme Court, the former being called the Supreme Court, the High Court of Justice, or the Court of Queen's Bench, the latter the Court of Appeal or the Appellate Division of the Supreme Court. Below these are various levels of minor courts, the chief being the County and District Courts which try civil and criminal actions by either judge or judge and jury as well as accept appeals from certain inferior courts within the county or district. At the bottom of the judicial hierarchy there exist a multitude of minor courts such as the surrogate courts for the probating of wills and estates; division courts for civil actions involving small sums of money; magistrates' courts for trials of minor offenses and preliminary inquiries; justices of the peace for the issuance of warrants and summonses; and family and juvenile courts for matters involving the family relationship exclusive of divorce.

Superimposed on this have been the federal courts. The federal government, although having the power to establish a federal system of courts, has never created one of general jurisdiction except in very limited matters. In fact, it has established only two significant courts: the Supreme Court of Canada and the Court of Exchequer in 1875. The former court, which since 1949 has been the final court of appeal in Canada, exercises an almost completely appellate and extremely wide jurisdiction. If more than \$2,000 is involved, almost any case can go to it. This is a completely different approach from that in the United States, where the Supreme Court will hear only cases of national significance. The Exchequer Court is a court of original but not general jurisdiction, dealing with patent and trademark, admiralty, and tax cases, suits against the crown, and certain other lesser federal matters. Thus, the Canadian court system, though not unitary in the English tradition, varies from the federal model supplied by the United States.

This refusal to adopt a completely dual system of federal and provincial courts seems justified on practical grounds and is, perhaps, inevitable in a sparsely populated country. There are obvious advantages in avoiding the duplication of courts and personnel. Also federal control over the appointment of provincial judges (s. 96) and review by the Supreme Court of Canada ensures, to a great extent, conformity in the interpretation of federal legislation by provincial courts. The absence of any federal court of both original and general jurisdiction, besides causing the greatest part of litigation in Canada to be dealt with in provincial courts, also means that there is virtually no problem of conflicting jurisdictions between provincial and federal courts as there is in the United States. The few jurisdictional problems stem from the legal notion that each province is an autonomous sovereign state. Thus, the intricacies of private international law are introduced into intraprovincial litigation. Fortunately, geography, population, and economics all work against the occurrence of a great many of these situations.

2. Beginning Actions and Pretrial Procedure.—Whether the cause of action is based on common law or equity, most civil actions in Canada are begun by writ of summons. In certain classes of actions, such as actions for liquidated demands, enforcement of mortgages or dower, the writ may be specially endorsed and become subject to summary judgment procedure. Thus, the plaintiff may specially endorse his writ with a statement of claim requiring the defendant to file an affidavit stating his belief that he has a valid defense on the merits. If such document is not filed, the plaintiff may immediately have judgment signed against him. When such an affidavit is filed the plaintiff may examine him upon it and move for judgment, but such motions are rarely successful. In many cases, however, such affidavits are not filed; hence this device has been widely used by litigants.

There are certain exceptions to this method of commencing actions. For example, in actions to enforce mechanics' liens the proceedings are begun by the filing of a statement of claim and proceeding immediately to trial and judgment before an official referee in a summary manner. Again, actions for the administration of a deceased person's estate or for the partition of an estate

are started by the service of an originating notice of motion, returnable in chambers, on the party from whom an account is claimed, or, in case of partition, on some of the parties interested, and the judgment may be granted or refused. Where a judgment is granted, the officer to whom the cause is referred adds all other necessary parties as defendants, and these persons are given an opportunity to contest the decision.

As a result of general acceptance of the fundamental conception of the adversary system, Canadian pretrial procedures seek to compel the parties to disclose the issues and merits of their case. Since litigation is expensive and its results uncertain, great emphasis has been placed on pretrial procedures to expedite settlements. To this end, parties have been required only to state the material facts relied upon, and courts have been given liberal powers of amendment to remedy errors in pleading. This has meant that greater importance is attached to subsequent examinations than to the preliminary statement. Examination upon discovery has become the most important aspect of pretrial procedure, and in almost all jurisdictions, except some in the Maritimes, oral discoveries have replaced discovery by interrogatories. Because the rules permit questioning on any issues pleaded, these examinations have become as broad as those at trial.

Where witnesses are aged, infirm, or outside the province, discovery may also be had through taking evidence from witnesses *de bene esse* (conditionally) for use at trial. Although the primary purpose of this is to preserve testimony, it also discloses it and thus facilitates settlements. Provision is also made for examination of relevant, nonprivileged documents, or property, and, in personal injury cases, of the injured person.

Criminal actions are begun by summons in the case of lesser offenses and by warrant in the case of more serious offenses, both summons and warrant being obtainable from a justice of the peace. In five provinces (Ontario, Nova Scotia, New Brunswick, Prince Edward Island, and Newfoundland) the grand jury has been retained, and its approval must be obtained to institute prosecution of indictable offenses.

3. Trials.—Trials in Canada, whether by judge and jury or judge alone, follow the English pattern. The traditional adversary system, with its sharp division of functions among judge, jury, and counsel, has been maintained rigidly. The only variant has been the gradual replacement of trial by judge and jury to trial by a judge alone. The only civil cases where a right to a jury trial still exists are the common-law actions of libel, slander, criminal conversation, seduction, malicious arrest or prosecution, and false imprisonment; there is no right to a jury in equitable actions; and in the remaining actions the judge is given discretion to exclude a jury. In practice, juries are empaneled in less than 2% of cases. Unfortunately, no comparable changes have been made in the procedural rules stemming from the adversarial theory, especially as it relates to matters of evidence. This has been at the root of many criticisms of the judicial system in Canada.

Similarly, in criminal cases, juries play a continually smaller role. In almost all indictable offenses, except for a relatively few minor offenses tried by a magistrate or judge alone, the accused is entitled to a jury. In only about 3% of these cases does the accused elect for a jury trial. In cases involving more serious offenses, such as rape or motor manslaughter, however, the accused must be tried by jury.

4. Enforcement of Judgment.—The last stage of a civil trial is the execution of judgment. In theory, execution of judgment should be an executive rather than a judicial act carried out by the crown rather than the individual; indeed, a writ of execution, by its terms, is a command by the crown to a sheriff to execute the judgment. In practice, however, the sheriff does nothing until spurred into action by the successful party. Thus, as the individual rather than the crown enforces the judgment, this concluding phase of litigation with its emphasis on regulated self-help is merely another example of the adversarial principle carried to its ultimate and rather abstract conclusion.

The problems which face the judgment creditor are almost entirely procedural because virtually all forms of property, whether legal or equitable, tangible or intangible, real or personal, are now

exigible. Discovery in aid of execution is provided in most jurisdictions to assist the creditor in his search, and generally this has worked well. His problems begin, however, when he attempts to seize the assets so found, because there is no unified procedure for all types of assets.

In practice, the commonly used procedures are by way of the writ of *fiery facias* and the garnishment order *nisi*. The first works a notional seizure from the date it is filed with the sheriff, but, except for realty, it requires actual seizure to be effective against bona fide purchasers. Of necessity this involves many additional expenses. Garnishment procedure, although simple in theory, has not worked well in practice, because to successfully garnish money there must be a "present indebtedness" of the garnishee to the primary debtor. This means, in the case of wages, the sum must not only have been earned but also be payable. Thus, if the wages are paid in advance they are not earned, and if they have been handed to the primary debtor they are not payable; in both cases the creditor's garnishment is ineffective because the requirement of a "present indebtedness" is not satisfied. The rationale for the existence of these rules is found in history rather than utility. In practice they only make the execution process expensive, haphazard, and inequitable, the procedural niceties providing opportunities for error to the creditor and evasion to the debtor. This is probably the least satisfactory phase of judicial administration in Canada.

In criminal cases and cases involving the custody of children there has been a tendency to place increasing reliance on reports of social workers, psychiatrists, psychologists, and other professional persons. Outside the sphere of criminal law, however, there has been little uniformity in this, and many experts have expressed doubts as to whether judges place much reliance on the material supplied them.

PRAED, WINTHROP MACKWORTH (1802–1839), English author and politician remembered chiefly for his humorous verse, was born in London on July 26, 1802, and educated at Eton (where he founded a celebrated periodical, *The Etonian*) and at Trinity College, Cambridge, where he had a brilliant career. He was called to the bar in 1829, and entered Parliament in 1830, representing successively St. Germans, Great Yarmouth, and Aylesbury in the Tory interest. In 1834 he was appointed secretary to the Board of Control, a step in government office which was confidently expected to lead him to great heights, and in 1838 he became deputy high steward of Cambridge University and recorder of Barnstable—various recognitions of his ability which his death from consumption on July 15, 1839, in London, brought to nothing. Praed engaged a good deal in miscellaneous journalism (his

Essays were collected in 1837), but his literary reputation rests on the most accomplished body of *vers de société* in English, such pieces as "The Vicar" and "Good Night to the Season" being unsurpassed in their subtle blending of humour, sentiment, and light satire:

Good night to the Season!—the dances,
The fillings of hot little rooms,
The glancings of rapturous glances,
The fancyings of fancy costumes;
The pleasures which fashion makes duties,
The praisings of fiddles and flutes,
The luxury of looking at Beauties,
The tedium of talking to mutes;
The female diplomatists, planners
Of matches for Laura and Jane;
The ice of her Ladyship's manners,
The ice of his Lordship's champagne.

Praed shared with Southey a talent for grim humour, as in "The Red Fisherman," and his verse epistles are the best since Swift. He wrote many political squibs, some of which, for example "Stanzas to the Speaker Asleep," have a bantering grace, the effect of which is moving as well as comic.

See W. M. Praed, *Selected Poems*, ed. by K. Allott (1953); D. Hudson, *A Poet in Parliament* (1939). (K. Ho.)

PRAEMUNIRE, in English law, an offense so called from the introductory words, *Praemunire facias A.B.* ("cause A.B. to be forewarned"), of the writ of summons issued to the defendant. The word came to be used to denote the offenses, usually ecclesiastical, prosecuted by means of such a writ, and also the penalties they incurred. From the 13th century papal encroachment increased, especially in two forms. One was the disposal of ecclesiastical benefices to men chosen at the papal Curia: this was the practice of provision (*q.v.*). The other involved judicial actions in the papal court, which either ran counter to decisions in the English royal courts or drew to the Curia business thought by royal lawyers to fall outside papal jurisdiction. The first Statute of Provisors (against provision) of 1351 was followed in 1353 by the Statute of Praemunire, which provided that any subject of the king who had litigated "out of the realm" in a matter properly belonging to the king's court should be allowed two months in which to answer for his contempt.

This statute was revised in 1365 and was followed, in 1393, by the so-called "great" Statute of Praemunire, primarily directed against Pope Boniface IX. In the 16th century it acquired great importance and was used by Cardinal Thomas Wolsey against William Warham, archbishop of Canterbury, in 1518. In 1529 Wolsey himself was found liable to the penalties of praemunire. The statute was used in 1530–31 by Henry VIII to obtain the submission of the English clergy.

The Royal Marriages Act of 1772 is the last which subjects anyone to the penalties of a praemunire.

See E. B. Graves, "The Legal Significance of the Statute of Praemunire of 1353," *Anniversary Essays in Medieval History by the students of Charles Homer Haskins*, ed. by C. H. Taylor (1929); W. T. Waugh, "The Great Statute of Praemunire," *English Historical Review*, vol. xxxvii (1922). (J. R. L. H.)

PRAENESTE (modern PALESTRINA), a very ancient city of Latium, lies 23 mi. (37 km.) ESE of Rome on the Via Praenestina on a spur of the Apennines facing the Alban Hills. On the summit of the hill (2,471 ft. [753 m.]), at Castel San Pietro, nearly a mile from the later Sullan settlement and the modern town of Palestrina, stood the ancient citadel, the site of which is now occupied by the church of San Pietro and a ruined medieval castle of the Colonna family. Portions of the southern wall of the ancient citadel, built of very massive blocks of limestone, are still to be seen; and two walls (also of polygonal masonry), which descended from the citadel to the town, can be traced. Praeneste's foundation was traditionally assigned to the mythological period (Virgil, *Aeneid* vii, 678); Odysseus' son Telegonus was one of the supposed founders. By the 7th century B.C. Praeneste was rich, powerful, and civilized with an Etruscanized culture. Its wealth is shown by the contents of the Barberini and Bernardini tombs, now in Rome in the Villa Giulia Museum. Tombs of the 6th and 7th centuries have not yet been found, but those of the 4th and 3rd

are known. Praeneste was famous for its *cistae* or bronze toilet chests of the 4th and 3rd centuries B.C., which in the beauty of their engravings reach a high level of artistic achievement. Reliefs in ivory also have been found.

In 499 B.C., according to Livy, Praeneste formed an alliance with Rome; during the 5th century it was exposed to attack by the Aequi. After Rome had been weakened by the Gallic invasion (390), Praeneste frequently fought against Rome and joined in the great Latin War of 340–338. It was punished by the loss of part of its territory, and it became an ally of Rome, possessing the right of exile (*ius exilii*); i.e., persons banished from Rome might live at Praeneste. The city remained loyal to the Roman cause, resisting both Pyrrhus and Hannibal. After 90 B.C. it received Roman citizenship and became a *municipium*. In the civil wars the younger Marius was blockaded in the town by the Sullans (82 B.C.); on its capture the male inhabitants were massacred in cold blood, and a colony of Sulla's veterans was settled on part of its territory, while the city was removed from the hillside to the lower ground at the Madonna dell'Aquila, and the temple of Fortuna was reconstructed. Under the empire Praeneste, from its elevated position and healthy air, became a favourite summer resort of wealthy Romans, whose villas studded the neighbourhood. Horace ranked it with Tibur and Baiae, though in fact it never rivaled Tibur or the Alban Hills as a fashionable residence. Still, Augustus resorted to it; here Tiberius recovered from an illness, and Hadrian and Marcus Aurelius had villas. Among private owners were the younger Pliny and Symmachus. The nuts of Praeneste were famous and its roses were among the finest in Italy. The Latin spoken there was somewhat unusual, and was ridiculed by Romans such as Plautus. A calendar, set up by the grammarian M. Verrius Flaccus in the forum of Praeneste, was discovered in 1771.

Its greatest claim to fame, however, was its great temple to Fortuna Primigenia (i.e., the first-born of Jupiter) and the oracle connected with the temple, known as the "Praenestine Lots" (*sortes Praenestinae*); these responses were given on slips of wood. An immense complex of buildings rose up the hillside like a pyramid in terraces, linked by ramps or stairs, and covered the area occupied by the medieval town. The higher section was later incorporated into the Palazzo Colonna-Barberini (begun in 12th century A.D.); in 1944 during World War II this was severely damaged by bombing, which revealed much of the ancient structure. This area has been restored (1952–55) and a museum housed in the palace. The lower buildings, near the cathedral, include the so-called "antro delle sorti," with marine mosaics, a temple, and the famous Nile mosaic. Little idea can be given here of the grandeur and complexity of the temple site. The cult was flourishing by 241 B.C., but the period of great building remains controversial: many (e.g., G. Lugli) would assign it essentially to Sulla, but Fasoli and Gullini (see below) date it c. 150 B.C. Moreover, while the complex is normally explained as upper and lower parts of a sanctuary, some believe that the lower buildings were not part of the *area sacra*. This immense and imposing sanctuary, probably the largest in Italy, was visible from a great part of Latium, from Rome, and even from the sea.

PRAESTÖ, an amt (county) of Denmark, embracing southeastern Sjaelland (Zealand), the island of Mön, and islets including Bogø and Nyord, is centred on the small town of Praestö. Area 654 sq.mi. (1,694 sq.km.). Pop. (1960) 121,976. Its gently undulating morainic surface with fertile clay loams forms an important mixed farming district. Impressive limestone cliffs occur at Stevns Klint and Möns Klint. The ports of Naestved (pop. [1960] 19,617) and Vordingborg (11,780) are the principal settlements.

(Ha. T.)

PRAETOR (derived from Latin *prae-ire*, "to lead, to precede") was the title borne by the consuls in the early republic of Rome (see **CONSUL**). Its military connotations remain in the ad-

jective *praetorius*, in such phrases as *castra praetoria* and *cohors praetoria* and its translation into Greek with the word *strategos*, "general." The praetorship was instituted as a patrician office for the administration of the civil law in 366 B.C. when the consulship was first held by a plebeian (see **PATRICIANS**). The praetor (later called *urbanus* when other praetors were added) was elected by the centuriate assembly (see **COMITIA**) as a junior colleague of the consuls, whose *imperium* (authority) was superior to his. He could hold military command, summon the senate in the absence of the consuls, and perform other public functions, but could not legally hold a consular or a praetorian election. The office was first held by a plebeian in 336.

Increases in the number of foreign traders and residents made necessary the creation of a second praetor (*praetor peregrinus*) to judge suits between foreigners and between citizens and foreigners, under whom considerations of equity began to relieve the strict application of the civil law. About 227 two praetors were added to govern the provinces of Sicily and Sardinia. The organization of the two Spanish provinces led to the addition of two more in 197, a number which remained fixed until L. Cornelius Sulla (dictator 81–79). The praetor had six lictors (two in the city), as well as the *toga praetexta* and the curule chair, while the praetors in Spain, such as Aemilius Paullus in 191–189, who had 12 lictors, usually received a consular *imperium*. Additional provinces and the creation of new courts to deal with extortion (149), treason (103), and murder (before 98) added to their duties. Finally, Sulla raised the number to eight and placed the series of courts regularly in their charge (extortion, bribery, embezzlement, treason, murder, and forgery), while continuing the *urbanus* and the *peregrinus*, each being allotted his jurisdiction before entrance upon office. This meant in practice that praetors served a year in Rome before proceeding to provinces as propraetors or proconsuls. Julius Caesar raised the number to 16, Augustus reduced it to 8, but added 2 new praetors of the treasury and raised it temporarily to 16 again. Later numbers vary according to fields of competence, sometimes, as with Agricola, too many for the fields to be allotted. Claudius abolished the praetors of the treasury, but two were created to deal with trusts (*fidei commissa*), another to deal with disputes between the *fiscus* (q.v.) and private citizens (Nerva), another as a guardian for minors (Marcus Aurelius), one in charge of the *centumviri* (q.v.; Augustus), and one for cases involving freedom of slaves.

Under the principate elections became a form determined by imperial commendation of candidates and the process of *destinatio*, but the magistracy remained an important stage in a senatorial career, as the command of a legion and of provinces of second rank were reserved for ex-praetors. The urban praetor's responsibility under the republic for the games of Apollo became a general praetorian responsibility for the major games.

From early in the history of the magistracy the praetor as a civil administrator issued an edict on entering office stating the procedure by which he would be guided. This edict, accepted and modified by succeeding praetors, became one of the most important factors in molding and adapting the Roman law to new conditions and the demands of equity and good faith. Under Hadrian this development ended when the "perpetual edict" was codified and published in definitive form, but praetorian jurisdiction in both civil and criminal law had already been circumscribed by imperial responses, judgments of the imperial consilium, and the jurisdiction of the emperor, the senate, and the urban and praetorian prefects.

In the late empire most praetorships disappeared but the *praetor urbanus* remained with the heavy burden of providing games, and also those who were guardians of minors and those who judged questions of freedom. The office became a *munus* ("public duty") instead of an *honor*.

Praetor was the title of the elected head of the Latin League, and of the chief magistrate in some Latin and Italian towns.

PRAETORIAN GUARD, the household troops of the Roman emperors. By the 2nd century B.C. Roman generals had a bodyguard known as the praetorian cohort (*cohors praetoria*). After the Battle of Philippi (42 B.C.) 8,000 veterans who refused discharge were formed into praetorian cohorts and shared between M. Antonius (Mark Antony) and Octavian, who later, as the emperor Augustus, stationed a number of cohorts (probably 9) in and around Rome, and in 2 B.C. appointed two equestrian prefects to command them (see **PREFECT**). Tiberius' powerful prefect Sejanus concentrated the praetorians in A.D. 23 in fortified two-story barracks on the Viminal Hill, just outside the walls of Rome to the northeast; the site is at present occupied by the Caserma Macao. The barracks were shared with the three (later four) urban cohorts, a police force under the *praefectus urbi*.

The cohorts were increased to 12 by either Gaius (Caligula) or Claudius. Vitellius enrolled 16 briefly in 69, but Vespasian returned to 9; later, possibly under Domitian, they were raised to 10 again and remained so until Diocletian. There is some doubt whether there were originally 500 or 1,000 men to a cohort; 1,000 is certainly the figure later on. A few cavalry were attached to them, but they themselves were foot soldiers. Their pay was roughly three times a legionary soldier's, and they served 16 years instead of 20. They were recruited from Italy and the romanized provinces until 193, when Septimius Severus disbanded the existing praetorians and replaced them with picked men from the legions; even before this their officers had as a rule had at least brief service with a legion.

The emperor's actual bodyguard was a separate smaller body, often of non-Romans, but the praetorians performed guard duties at the imperial palace (for which they wore the civilian toga), and a part of them was always with the emperor. Hence some of them served in foreign wars; Nero even sent a contingent of praetorians on a reconnoitering expedition into Nubia. They also acted on occasions as a political police, carrying out arrests and executions, and had various ceremonial duties.

Although the frontier legions took as much part in appointing emperors, the praetorians figure in such sensational incidents as the accession of Claudius (41), the disorders of 68–69, the lynching of Domitian's murderers (97), and, in 193, the murder of Pertinax and the subsequent auction at the praetorian camp, where the Roman Empire was knocked down to Didius Julianus for a bounty of 6,250 denarii per praetorian. This last incident probably influenced Septimius Severus in his decision to reorganize them. After this they murdered Elagabalus (222), and Balbinus and Maximus (238). Diocletian reduced their numbers. Many of them fell with Maxentius at the Battle of the Milvian Bridge (312), and in the same year Constantine finally disbanded them (but not the urban cohorts).

See R. Durry, *Les Cohortes prétorienne* (1938); A. Passerini, *Le coorti pretorie* (1939).

PRAETORIUS, MICHAEL (1571–1621), German music theorist and composer, highly regarded by his contemporaries, was born in Kreuzberg (Thuringia) on Feb. 15, 1571. He adopted the latinized form of the German name Schultheiss. After studying at Frankfurt an der Oder he was organist and *Kapellmeister* to the bishop of Halberstadt, and from 1612 was *Kapellmeister* at the court of Wolfenbüttel until his death there on Feb. 15, 1621.

Praetorius was extremely zealous for the advancement of music. An admirer of Italian music, he had a predilection for rich and varied settings for voices and all kinds of instruments. His output was considerable and various. The most important collections of his works are the settings of evangelical church songs called *Musae Sioniae* (nine parts, 1605–10), partly for 8 to 12 voices in the Venetian double choir style, and partly in simple four-part style; and the *Puericinium* (1621), where the hymn strophes receive very varied treatment, foreshadowing the choral cantata. Praetorius published much music other than his own, and in his collection *Terpsichore* (1612) he introduced several hundred foreign dance pieces to Germany.

The three surviving parts of Praetorius' great work *Syntagma*

Musicum (1614–18) comprise a Latin treatise on music theory, a lavishly illustrated account of instruments, and an exposition of musical forms and methods of performance; the fourth part, on counterpoint, was not completed. (C. P. Co.)

PRAGMATIC SANCTION, a pronouncement by a sovereign on a matter of prime importance, such as the relationship between church and state or the dynastic succession.

The Pragmatic Sanction of Bourges (July 7, 1438) was issued by Charles VII of France after an assembly had examined the decrees of the Council of Basel (q.v.). It established the "liberties" of the Gallican Church (see **GALLICANISM**), in particular by declaring that the successors to vacant prelacies in France should be elected by their chapters or convents unless the vacancy arose from the previous occupant's death *in curia*, that is, on a visit to Rome, in which case the pope could nominate his successor. In practice, election usually meant the election of the French king's nominee. Revoked by Louis XI in 1461, but reasserted from time to time later, the Pragmatic Sanction was ultimately superseded by the Concordat (q.v.) of Bologna between Francis I and Pope Leo X (1515).

The Holy Roman emperor Charles VI (q.v.) designed his Pragmatic Sanction of April 19, 1713, to preserve the integrity of the Habsburg inheritance (see **AUSTRIA, EMPIRE OF; HABSBURG**). It stipulated that if Charles left only daughters, the undivided heritage should go to the senior one and then to her descendants by primogeniture; and that if Charles died childless, it should go to his deceased brother Joseph I's daughters or their descendants, likewise in order of primogeniture. Charles laboured for years to induce the estates of the various Habsburg lands, the German princes, and the other European powers to assent to this Pragmatic Sanction; and the Peace of Vienna (1738–39), after the War of the Polish Succession, seemed to guarantee it, with Maria Theresa (q.v.) as the prospective beneficiary. When Charles died (1740), however, the War of the Austrian Succession (q.v.) broke out.

In Spain, by his Pragmatic Sanction of March 29, 1830, Ferdinand VII (q.v.) promulgated his predecessor Charles IV's unpublished decision of 1789 revoking the Salic law of succession (q.v.), so that the subsequent birth of Ferdinand's daughter, the future Isabella II, deprived his brother Don Carlos (q.v.) of his right as heir presumptive. The first Carlist War broke out on Ferdinand's death (1833).

PRAGMATISM, a term of philosophy (from Greek *pragmata*, "acts," "affairs," "business") chosen by the U.S. logician C. S. Peirce (q.v.; 1839–1914), apparently in the course of discussions with William James and others in the 1870s, to stand for a way of making our ideas clear or, more accurately, for "a method of logic a method of determining the meanings of intellectual concepts, that is, of those upon which reasoning may hinge" (*Collected Papers of Charles Sanders Peirce*, ed. by Charles Hartshorne and Paul Weiss, vol. 5, p. 464; Cambridge, Mass.: Harvard, 1935). Pragmatism was popularized by the writings of James during the first decade of the 20th century; but the later publication of Peirce's *Collected Papers* showed that the two fathers of the doctrine diverged considerably in their interpretations of it.

Peirce's original formulation of the pragmatist principle was: "Consider what effects, that conceivably might have practical bearings, we conceive the object of our conception to have. Then our conception of these effects is the whole of our conception of the object" (*Collected Papers*, vol. 5, p. 2). A more readily intelligible and apparently equivalent formula of James is that "the whole meaning of a conception expresses itself in practical consequences, either in the shape of conduct to be recommended, or in that of experience to be expected if the conception is true, which consequences would be different if it were untrue, and must be different from the consequences by which the meaning of other conceptions is in turn expressed" (William James in James Mark Baldwin, *Dictionary of Philosophy and Psychology*, New York: Macmillan Company, 1902). Both statements make a point which is closely related to the central teaching of British empiricism (see **EMPIRICISM**); but where traditional empiricism has taught that none of our conceptions (or the verbal expression of them) has a meaning unless it has been derived from some elementary sensory

impression, pragmatism teaches that no conception has meaning unless it can be applied, directly or indirectly, in the location and description of something of a kind that might be revealed to our senses.

Regarded in this way, the positive content of pragmatism is simple enough; viz., that all our conceptions, even the most abstract, derive their peculiar point or meaning from things or from differences in such things as we can actually observe and point to. But pragmatism has certain features which constitute a further important development of traditional empiricism. Two things differ practically, or differ for us, insofar as we find ourselves compelled to treat them differently or to expect different reactions from them. Similarly, according to pragmatism, two words (or conceptions) have different meanings not because of some direct relation between word and thing in either case but in virtue of their different uses; i.e., in virtue of the different ways in which they help to express or communicate different procedures—involving expectation and adjustment—with regard to the things in question. Thus pragmatism contains, or rests upon, what might be called a procedural theory of meaning. Moreover, Peirce's principle has proved a most searching tool of criticism. We are all liable to confuse highly abstract and erudite conceptions, not only in metaphysics but also in the mathematical and natural sciences; but if one conception does not differ "practically" (in Peirce's sense) from a second, then our employment of it adds nothing to our employment of that second conception. Again, we are sometimes tempted to engage in speculations which have no assignable "practical bearings"; but in that case, according to pragmatism, our thoughts and words have no assignable meaning. Men of science, Peirce claimed, have always unconsciously applied the pragmatist method to distinguish better conceptions which common sense treats as one or to identify conceptions which common sense has traditionally regarded as several. Unfortunately philosophers have not made much use of the method.

Thus far Peirce and James were in agreement; the grounds of their divergence were more complex than either of them appreciated. In the first place, for example, James wished to use the pragmatist method to vindicate—not simply to elucidate—our basic moral and religious beliefs by reference to their beneficial practical consequences on our conduct and temper. Peirce was on the whole averse to applying the pragmatist method to moral or to religious concepts, which seemed to him of a kind that could not be made clear; and certainly he was flabbergasted by some of James's ventures in this field. Second, as the basis, to a large extent, of these ventures, there was James's "pragmatist" account of our conception of truth, his view that a belief or theory is true insofar as it "works" or "pays." To be sure, James has often been cruelly misunderstood in this connection, yet it is questionable whether his account of truth can be regarded as an inevitable—and still more questionable whether it can be regarded as the one and only possible—result of applying the pragmatist method to our normal uses of the word "true." Third, underlying most of James's applications of the pragmatist method (including the case of "truth") was his strong prejudice in favour of whatever is concrete and particular and against whatever is abstract and general. This finds expression in his statement that the meaning of any proposition "can always be brought down to some particular consequence in our future experience . . . the point lying rather in the fact that the experience must be particular, rather than in the fact that it must be active" (William James, *Collected Essays and Reviews*, p. 412; New York: Longmans, Green & Co., 1920). Peirce explicitly repudiated this view. Fourth, the last-named prejudice of James was closely connected with his hankering after that form of metaphysics—"radical empiricism" he called it—according to which the fundamental reference of all discourse is "pure experience," something which is in itself neutral as between mind and matter and which is exemplified in the content of our sensations and the felt transitions between our sensations. (For example, "truth" on this view stands for certain experienceable transitions between one "bit" of experience and other bits with which it can be brought into harmonious and successful relation.) James openly confessed that he was attracted to pragmatism be-

cause he thought it would help him to vindicate his radical empiricism—of which indeed it seemed to him to be simply the logical facet. Peirce on the other hand vehemently rejected the suggestion that any doctrine of logic should be preferred for its metaphysical affinities. "Pragmatism is no doctrine of metaphysics."

Of these four grounds of divergence the last two are fundamental. In them we see the transition from Peirce's account of the meaning of a term or statement as an attribute of certain prescribable and justifiable procedures to James's account of it as an attribute of certain describable, because individually experienced, processes. The illegitimacy of this transition seemed plain to Peirce from the fact that his pragmatist principle was put forward, as has been said, as a method of "determining the meanings of intellectual concepts, that is, of those upon which reasoning may hinge." For all reasoning is, in Peircian phrase, subject to "logical control" (i.e., to agreed logical canons); but whatever is amenable to control by rules must be in the nature of a habit or general procedure of action. Hence it can only be to concepts (or their verbal expression) which are irreducibly general (i.e., such that they can be employed by any rational being in any situation of appropriate general kind) that the pragmatist principle can apply. Alternatively we can say: Pragmatism, according to Peirce, teaches that our descriptions of things are to be understood as ways of dealing with those things—but of dealing with them from the standpoint, in some respects highly specialized, but in other respects entirely general, of reasoning; i.e., of finding out how observation, hypothesis, deduction and checking of consequences shows them to behave. But while making this protest against James's misuse of his pragmatist principle, Peirce was no less strenuous than James in emphasizing its empiricist purpose; only insofar as an intellectual concept (or its verbal expression) refers to "compulsory perceptions" of a certain sort—perceptions forced upon anyone who uses it—does it possess distinctive and genuine meaning.

Largely because of these disagreements between its originators, partly also because of their respective literary failings—James's writings at their worst are intolerably slapdash, Peirce's at their worst distressingly obscure—pragmatism was subjected during the first quarter of the 20th century to scathing criticisms from philosophers both of the realist and of the idealist schools. For later readers, the annals of this interschool battle are neither lively nor illuminating.

But the inner vitality of Peirce's pragmatist teaching is sufficiently shown by the variety of first-class minds that subsequently described themselves or allowed themselves to be described as pragmatists. Among these may be mentioned the English philosopher F. C. S. Schiller, whose very uneven writings contain some admirable expositions of the "question-and-answer" character of all purposive thinking; John Dewey (*q.v.*), whose "instrumentalist" theory of knowledge owes much to Peirce and whose naturalistic metaphysics of experience would have appealed greatly to James; G. Mead, who developed in the most suggestive manner Peirce's conception of inquiry as a socially controlled activity. C. I. Lewis drew on Peirce's teaching to restate the Kantian distinction between a priori and empirical elements in knowledge.

PRAGUE (Czech PRAHA), the capital city of Czechoslovakia, is situated along both banks of a large meander of the Vltava (Ger. Moldau), a tributary of the Elbe. The Vltava is there crossed by 13 bridges. Prague lies 650 ft. (198 m.) above sea level and is approximately 160 mi. (255 km.) NW of Vienna and 75 mi. (120 km.) SE of Dresden. Area 72 sq.mi. (186 sq.km.). Pop. (1961) 998,493.

The modern town has spread along the winding riverbanks, up

CAMERA PRESS—PIX FROM PUBLIX

VIEW OF PRAGUE ACROSS CHARLES BRIDGE AND VLTAVA RIVER, WITH HRADCANY PALACE AT UPPER RIGHT

the steep terraced hill slopes, and into the side valleys as well as the surrounding high ground. The hilly position of the town forms a serious barrier to modern communications but adds greatly to its beauty which is enhanced by the many medieval and Baroque buildings with their towers and spires and by the numerous parks, of which Stromovka and the Petrin orchards and gardens are the most extensive. A few industrial districts are situated on the left bank, but the chief factories are along the right bank in the north-western part of the town (Vysocany-Liben) and a new industrial quarter is growing up in the eastern sector. The residential quarters and new housing estates lie farther from the centre and form part of greater Prague, which has engulfed the surrounding towns.

The historical parts of the town, which have retained their ancient appearance, are kept up by the state. The vast 16th- to 17th-century fortified palace on Hradcany Hill, now the residence of the president of the republic and formerly that of the ancient kings of Bohemia, dominates the entire town. The castle has a number of halls including Vladislav Hall in Late Gothic style and the Spanish Hall in 17th-century Baroque. In the inner castle yard stands St. Vitus Cathedral, begun in 1344 and finally completed in 1929. Other important buildings on the castle hill include the Romanesque basilica of St. George (912) and the Renaissance Belvedere. The Little Quarter below the castle is a district of picturesque streets overshadowed by the Baroque dome of St. Nicholas' Cathedral (1703). Overlooking the many fine squares and narrow streets stand numerous palaces, now used for public purposes. The Little Quarter is joined to the Old Town by the Charles Bridge (1357), now flanked by Baroque statues. The Old Town abounds in monuments and relics of the history of the district. Its most remarkable features include the Old Town Square with the ruins of the town hall, burned down during the 1945 uprising, and the ancient clock of the seasons. Opposite them is the 14th-century Tyn Church, in the Prague Gothic style, containing the tomb of Tycho Brahe, the Danish astronomer. The church was the religious centre of the Hussite movement and in the centre of the square is a monument (1915) to John Huss. Nearby are the remnants of the old Josef's town (the Jewish ghetto) and a 13th-century Jewish cemetery and synagogue.

Passing out of the Old Town through the 15th-century gate, or Powder Tower, to Prikopy, the site of the former moat around the old walls, there is a change from ancient beauty to modern, commercial life with department stores, hotels, restaurants, and offices. The centre of the modern town is Wenceslas Square, with the statue of St. Wenceslas (1913) and the National Museum (1894). Other sights worth mentioning include the Tyl Theatre, where

Mozart's *Don Giovanni* was first performed; the National Theatre (1883); Vysehrad Hill with the church of St. Peter and St. Paul and the poets' corner; the national monument at Zizkov with the mausoleum; and the statue of the Hussite leader Jan (John) Zizka by Bohumil Kafka (1950).

Education and Culture.—Prague University, founded by Charles IV in 1348, was the first in central Europe. The Technical University (1707) has developed a great number of faculties. Other centres of learning include the Prague School of Economics, the arts and crafts school (1885), the Academy of Graphic Arts (1799), the Academy of Music, Dancing and Film (1948), the Conservatoire (1811), and the Institute of Physical Training. The Czechoslovak Academy of Sciences carries out its research in numerous buildings.

Besides the National Museum (founded 1818) there are a technical, an ethnographical, an arts and crafts, and a Jewish museum, and museums of Czechoslovak literature and of the Working Class Movement. The National Gallery contains pictures and sculptures by famous Czech, Slovak, and foreign artists and has a unique collection of Gothic art. The Art Gallery of Prague Castle, opened in 1965, displays the remnants of the once famous art collection of Rudolf II. In addition to the central municipal library there is the university library which owns a collection of precious manuscripts and old prints. Prague has 28 theatres, including 3 belonging to the National Theatre, where drama, opera, and ballet are performed, special theatres for children (puppets), and a theatre of recorded music. A number of symphony orchestras are headed by the Czech Philharmonic.

Industry and Communications.—As a capital, Prague is the seat of the ministries, foreign trade corporations, the chamber of commerce, and the highest church dignitaries. Though the main town of the Central Bohemian region and housing its regional administrative offices, the town has autonomous status on a par with a region. For purposes of local administration it is divided into ten independent districts. It is also a big industrial town and with its surroundings now forms the largest centre of engineering in the entire country. Most of the industries are highly specialized, with more than half the production capacity devoted to heavy and precision engineering. All works have been greatly expanded and brought up to date since nationalization in 1945, and many new factories have been built. Products include automobiles, motorcycles, buses, airplanes, railway engines and coaches, machine tools, boilers, mining and foundry equipment, cranes, electrical equipment, turbines, machinery for the chemical industry, etc. Other important industries include food processing (mills, breweries, a refrigeration plant, dairy produce, and meat products) and the manufacture of clothing and chemical and pharmaceutical products. There are also printing works, phonograph and film industries, and tanneries.

The electric power for the city is brought by grid from the brown coal basin in northwestern Bohemia, which also supplies gas. There are hydroelectric power stations on the Vltava at Orlík and Stechovice, at Vrane, and at the Slapy Dam (1955).

Prague is the meeting place of rail and air routes joining the north and south of Europe and, especially, the east and west. There are three main-line railway stations. The airport, Ruzyně, is 7 mi. (11 km.) from the centre of the town. Local transport services (streetcars, trolley buses, buses) extend over 100 mi. (160 km.), with an additional 60 mi. (96 km.) of local railway lines. Holesovice, the inland harbour, is the terminus of Elbe-Vltava shipping.

History.—There is evidence that the site on which Prague stands has been inhabited since Paleolithic times. Its fertile soil and mild climate (average temperature 1.6° C [35° F] in January and 19.4° C [67° F] in July), its easy fords across the river and the possibilities of defense and of trade, favoured the growth of a town which later became the political centre of Bohemia (9th century). The ruling dynasty of the Premyslids (until 1306) succeeded in defeating all foreign attempts at subjugation and preserved the territorial integrity of the country.

The earliest settlements, documented from about the 9th century, were found at the foot of the ancient castles built on the

dominating hilltops, Vysehrad on the right bank of the river and Hradcany on the left, which were residences of the Bohemian princes and later kings. On the right bank a small settlement formed the market centre for the isolated homesteads in the neighbourhood. This developed into Stare Mesto (Old Town), and on the opposite bank King Premysl Otakar II founded Mala Strana (Little Quarter) in 1257. Under Charles IV, king of Bohemia (1346-78) and Roman emperor, Nove Mesto (New Town) was built adjacent to the old town, and the ghetto was also developed.

In the 14th century Prague was already one of the most important towns in central Europe. It was a vital crossroad of trade routes running from north to south and from east to west, and it was also a centre of culture, its university attracting scholars and students from all over Europe. Charles IV, besides founding the university, was personally responsible for extensive building activities in the town according to an elaborate plan. Outstanding examples are the Charles Bridge joining the Little Quarter to the Old Town, the Carolinum (the central auditorium of the university), and the town hall as well as several churches and monasteries in the New Town.

Foreigners who came to settle in Prague contributed toward its growth, and the German and Italian merchants grew into a rich patriciate who ruled the town. They could usually rely on the support of the king in all measures designed to curb the guilds formed by Czech craftsmen. Many conflicts arose between the two social groups and were conducted with an eye to nationality. Disputes between guild masters and their journeymen incited numerous town paupers to minor uprisings, which went on prior to and throughout the period of the Hussite Wars.

Among the scholars of the university, John Huss soon assumed a leading role in the struggle that ended with the Kutna Hora decree (1409), in which Wenceslas IV granted the Czechs a predominant position in the university. Huss, basing his criticism on the theoretical writings of Wycliffe which he developed further, publicly voiced sharp criticism of the church and the secular power it exerted as well as the sinful life of the clergy. His sermons, delivered in the Bethlehem Chapel (restored to its original appearance in 1954), gained him support among the common people. Repressive measures on the part of the church and the patriciate led to violent uprisings in 1419 during which the radical elements, led by John Zelivsky, rose to power. Prague came to the aid of the people's uprisings in the countryside, which were led by the Hussite supporters, who had established a model community at Tabor in southern Bohemia. The Taborites, led by Zizka, helped Prague and gained a decisive victory in the Battle of Vitkov Hill in 1420. After the defeat of the radicals the city patriciate and the rich burghers gradually changed sides until, toward the end of the Hussite Wars, Prague stood in the ranks of the opponents. (See HUSSITES.)

The town's significance grew under the rule of George of Poděbrady and the Jagiello dynasty, during which Prague was enriched by the building of churches and halls (e.g., Vladislav Hall) in Late Gothic style. The following centuries witnessed the growing opposition to the Habsburgs who had become kings of Bohemia on the death of Louis II of Hungary and were endeavouring to reintroduce Catholicism by force. Opposition to those measures and attempts to put an end to the feudal might and Catholic influence of the monarchy and the church led to the Defenestration of Prague (May 23, 1618), one of the steps leading to the Thirty Years' War (see BOHEMIA: *Habsburg Rule, 1526-1918*).

During the Hussite Wars the town was a Czech stronghold, but after the defeat of the Protestants at the Battle of the White Mountain in 1620, and after the public execution of Czech noblemen and Prague commoners on the Old Town Square in 1621, the German predominance increased again. Prague ceased to be the chief town of the German empire and its significance began to wane. At the very end of the Thirty Years' War the town was partially occupied by Swedish armies and shared in the general chaos and decline suffered by the whole of central Europe for many decades after the cessation of hostilities. During the Seven Years' War (q.v.) the neighbourhood of Prague was the scene

(May 1757) of the Battle of Prague in which Frederick II the Great defeated the Austrians.

In the Baroque period, rich merchants and the mainly foreign nobility (German, Spanish, Italian) who had settled in Prague and its surroundings invited some outstanding architects and artists, who were later aided by Czech masters, to embellish the town. At the time when Mozart lived in Prague, it had large gardens, aristocratic palaces, and Baroque churches, especially in the Little Quarter.

Prague's most rapid expansion, however, came with the advent of industrialization which took advantage of the proximity of coal mines and ironworks at neighbouring Kladno and Kraluv Dvur. The population, which was only 140,000 in 1843, was 849,000 in 1930. Efforts are being made to prevent the further growth of the town. In the 19th century, with the rapidly changing social and economic relations within its population, Prague became the centre of a great cultural drive for the revival of the Czech national heritage. During the revolutionary wave of the year 1848, a Slav congress was convened at Whitsuntide, and the townspeople attempted to resist the repressive measures of the Austrian generals, but the fighting on the barricades ended in surrender. Nevertheless, Czech feeling and cultural life gained in significance and in 1861 the Czechs won a majority in the town administration. At the conclusion of World War I the independent republic of Czechoslovakia was established with Prague as its capital city. In March 1939 the country was occupied by the Germans, and Hitler established a protectorate with a puppet government. On May 5, 1945, the citizens of Prague rose against the German occupying forces, erecting barricades and holding out against superior German forces until the entry of the Soviet army four days later. Prague once again became the capital of the Czechoslovak Republic. (T. GR.)

PRAGUERIE, a revolt of princes and other nobles against Charles VII of France in 1440, so named in allusion to contemporary movements at Prague and elsewhere in Bohemia. As early as April 1437 a number of princes, excluded from the royal council, had unsuccessfully plotted to reassert their influence. In 1439 the king, inspired by the constable de Richemont (see ARTHUR III, of Brittany), issued the first of his great ordinances for military reform, which forbade the raising or maintenance of troops without his permission. The king's action strengthened the princes by bringing to their support those mercenary captains whose existence was threatened. Charles I, duc de Bourbon, and Jean II, duc d'Alençon, were the real leaders of the revolt, though the 16-year-old dauphin, later Louis XI, was induced to put himself at its head. They were abetted by John V of Brittany; by Louis, comte de Vendôme; by Jean IV, comte d'Armagnac; by Jean, comte de Dunois; and by Georges de La Trémoille, Richemont's old enemy. Alençon and the dauphin began the revolt in Poitou in February 1440, but were soon outgeneraled by Richemont. They then withdrew to Bourbon territory, but the king's artillery reduced their strongholds, and in July peace was made at Cusset, on very generous terms.

The rebels had proposed peace with England and a lessening of taxation, but the towns and the people stood loyally for the king. An attempt to renew the Praguerie through an assembly at Nevers in 1442 was brought to nothing by Charles VII's diplomacy.

PRAIRIE, the grassland biome (formation) of North America, the main body extending from southern Alberta to Texas and from the western arid desert eastward to contact with the humid forests. Other grasslands are the desert plains, extending southward from western Texas and Arizona into Mexico; the California prairie of central California; and the Palouse prairie of the northwestern states of the U.S. Grasslands ecologically equivalent to various prairies, including the steppe of the U.S.S.R., the veld of South Africa, and the pampas of South America, occur on all continents.

Perennial grasses gave the prairies their special character, but numerous colourful flowering plants, particularly legumes and composites, were conspicuous in spring and autumn. Bison and pronghorn antelope, grazing animals originally abundant on the prairies, disappeared in the earliest days of exploration and settle-

ment. The coyote, jack rabbit, badger, prairie dog, prairie chicken, and many kinds of grasshoppers, robber flies, and other insects are representative of a rich variety of animal life.

Prairie climate is marked by low, irregular rainfall, high summer temperatures, strong winds, high rates of evapotranspiration, and intense late summer drought, and is increasingly rigorous from east to west. Along this gradient of decreasing water supply tall grass prairie, of sod-forming grasses 8–10 ft. high, occupied the more humid eastern area to about the 100th meridian, where it graded into the mixed prairie of bunch and sod grasses reaching heights of about 4 ft. Westward, on the high plains leading to the Rocky Mountains, sod grasses only a few inches high characterized the short grass plains.

Deep, fertile, organic soils and climate favourable to grain farming led to early destruction of most prairies; only vestiges remain in the highly productive corn and wheat belts. (M. E. B.)

PRAIRIE CHICKEN (**PRAIRIE HEN**), the name for two species of North American grouse that inhabit the west- and south-central prairies from Louisiana (rarely) and Texas to Manitoba and Alberta. The brownish, chicken-sized greater prairie chicken (*Tympanuchus cupido*), of which the extinct heath hen (*q.v.*) was a subspecies, has a short, rounded tail and dense barred patterning on the underparts. The male has a neck tuft of ten or more dark, rounded feathers that are raised when the orange air sacs are inflated during the community courtship display. The females, enticed by the performance, gather about and choose their mates. After mating, the female deposits about a dozen eggs in a cleared area and incubates them for about three weeks. The lesser prairie chicken (*T. pallidicinctus*), a smaller and paler version, is largely restricted to the central part of the range. Prairie chickens are fine game birds but are not important economically.

PRAIRIE DOG, the name for heavy-bodied, short-tailed burrowing rodents of the genus *Cynomys*, of the squirrel family, formerly abundant throughout the plains of the western United States and northern Mexico but now greatly restricted. These gregarious animals live in colonies, or "towns," formed of elaborate burrows and raised entry mounds.

Of the several species known, the black-tailed prairie dog (*C. ludovicianus*) has the widest range, occurring sparsely over the Great Plains. It weighs about 2 lb. and measures about 16 in., 3 to 4 in. of which is tail. The pelage is mainly cinnamon brown; the terminal one-third of the tail is black and the underparts are buffy white. Two to ten pups are born in late spring or early summer after a gestation period of about a month. They mature at about two years of age and live about another six years.

The prairie dog modifies its environment in building its towns: fast-growing vegetation for food is encouraged and elimination of dense cover favourable to predators such as bobcats and coyotes is effected. The funnel-shaped entry mounds, 1–2 ft.

high and 5–6 ft. across, provide high and dry access to burrows and serve as elevated lookout posts. Territories, or coterie, within a town are well defined and defended by members. Recognition "kissing" and grooming afford the frequent contact necessary to maintain the social structure of each coterie. The prairie dog's bark (its only resemblance to a dog) is a short nasal yip, varied to convey alarm, urgency, or security (the territorial call).

The smaller, white-tailed prairie dog (*C. leucurus*) differs further from the black-tailed in living at higher elevations, in building smaller colonies, and in hibernating. See also RODENT.

PRAIRIE DU CHIEN, the seat of Crawford County in southwestern Wisconsin, U.S., owes its existence to the historic military and economic importance of its site, a point on the Mississippi River about 3 mi. above the mouth of the Wisconsin River. The French and British each maintained a trading post and fort there before the territory became part of the United States in 1783. Ft. Crawford, erected in 1816, was for the next four years a link in the chain of military outposts guarding the Indian frontier. After 1820, when the American Fur Company erected a depot there, the settlement continued to be the area's trading centre. The development of varied industries ensured its permanence and in 1872 it received its city charter. Campion Academy, located in the city, is a widely known residential high school for boys. Villa Louis, home of Hercules Dousman, a factor of the American Fur Company, is maintained by the state historical society as a museum. For comparative population figures see table in WISCONSIN: Population. (R. F. F.)

PRAIRIE PROVINCES, the three Canadian provinces of Manitoba, Saskatchewan, and Alberta, located in the northern Great Plains region of North America. The prairie provinces form the great wheat-producing region of Canada and are its chief source of petroleum and natural gas. See ALBERTA; MANITOBA; SASKATCHEWAN. See also CANADA: Geographical Regions.

PRAKRIT LANGUAGES, in its widest sense, denotes those languages of India which chronologically are Middle Indo-Aryan as distinguished on the one hand from Old Indo-Aryan, i.e. Vedic and Sanskrit, and on the other hand from Modern Indo-Aryan, i.e., the present-day languages of north India and Pakistan (see INDO-ARYAN LANGUAGES). It is thus used by modern scholars both in the west and in India. In this sense it includes the literary Prakrits and Apabhramśas used by Hindu, Jain, and Buddhist writers, the languages of many inscriptions and other non-literary documents ranging from the 3rd century B.C. to the 4th century A.D., the Pali language of Southern Buddhism, and Buddhist Hybrid Sanskrit, in which the Northern Buddhist scriptures were written. The word Prakrit has been used in more restricted senses, especially by the scholars of medieval India. Some have included only the four most important literary Prakrits; others have extended the list greatly, some even to include the Dravidian literary languages, which are not Indo-Aryan at all but have borrowed many Indo-Aryan words. In general these Indian scholars have included only the literary Prakrits used by Hindu and Jain writers, excluding the Buddhist languages and the inscriptions. Prakrits. They have listed and characterized briefly many varieties which are claimed to be vernaculars, but of which nothing is otherwise known. There was a tendency to exclude the Apabhramśa dialects.

Several etymologies have been given of the Sanskrit word *prākṛta* which denotes these languages. One is that it is derived from *prākṛti* "nature" and means "the natural language" as opposed to Sanskrit (*saṃskṛta*), "the refined (or literary) language." Another involves *prākṛti* in its meaning "basis"; *prākṛta* is then "derived from the basis (Sanskrit)." In either case it is implied that Sanskrit is the norm and the Prakrits are departures from the norm and in a way inferior.

Two slightly differing dialects of Old Indo-Aryan became literary languages in the last two millennia B.C. One is that of the Vedas. The other is classical Sanskrit as formulated by a succession of grammarians ending with Pāṇini (probably 5th century B.C.). From a very early period other dialects were already developing, differing from these two in the direction of Middle Indo-Aryan. The literary languages after their standardization

remained practically unchanging in usage, but the vernaculars continued to diverge. As time went on, the users of the literary languages composed in the literary forms but spoke normally in dialects which were closer to Middle Indo-Aryan. There are even traces of their vernaculars, i.e., Prakritisms, to be found in their literary compositions.

The Prakrits in their turn began to be written, and many of them received literary cultivation. The early chronology is very uncertain, but it may be that the earliest literature is the religious texts of the Buddhists and Jains. The Buddha (6th-5th centuries B.C.) directed that each of his disciples should teach in his own vernacular dialect. It is thought that in the first few generations after the Buddha numerous Middle Indo-Aryan dialects were used in preaching and teaching. This state of affairs seems to be reflected in the multiplicity of Prakrit dialects found in the religious inscriptions of the Buddhist emperor Aśoka (3rd century B.C.). As certain Buddhist centres gained influence, the dialects of these centres came to be used as literary languages to the exclusion of the others, although it is notable that there was much dialect mixture. These teaching dialects, like Sanskrit itself, became standardized, and gradually the spoken vernaculars diverged from them. Of the Buddhist languages, Pali became the standard language of Southern Hinayāna Buddhism and the vehicle of a great body of canonical and exegetical literature. Other Buddhist schools, including many of the Mahāyāna schools, which are known as Northern Buddhism, seem to have used another Prakrit for a voluminous literature. As controversy with Hinduism began to flourish, Sanskrit came to be used by Buddhists, especially in polemic philosophical discourses. The use of Sanskrit infected this Prakrit, and resulted in a partial sanskritization of the prose written in it and even of verse texts. The result is that there survive no pure examples of this hypothetical Prakrit; the texts that survive are all more or less sanskritized, and the language is generally known now as Buddhist Hybrid Sanskrit (BHS). Both chronology and locality are very uncertain. It may be that BHS originated in a more westerly Prakrit dialect and Pali in a more easterly one, which however is still to be identified as central or west central in the Ganges valley. Crystallization of both dialects was complete in the pre-Christian period. A version of one Buddhist text, the Dhammapada (Pali and Prakrit Dhammapada), was found in a central Asian excavation at the end of the 19th century, written in a Prakrit which was different from that at the base of BHS and which belonged originally to north-west India. In all probability there were in the early centuries of Buddhism literatures in other Prakrits than these three that have survived.

For the Jain religion the situation is somewhat similar. The canonical texts of the Śvetāmbara (Shvetambara) sect are in two dialects of Ardhamāgadhī. Later texts, especially commentaries on the canon, but also others such as the epic *Pañcamaṇḍikā* of Vimala Sūri (perhaps 4th century A.D.) are in Jain Māhārāṣṭrī. The Digambara sect used Jain Śāurasenī.

In the literature of the Hindus, also, Prakrit in several dialects came to be used probably at the end of the pre-Christian era. Later, Māhārāṣṭrī was especially used in composing lyric poetry, possibly on the basis of a popular oral lyric in the dialect; it began to flourish in the 3rd-4th centuries A.D. The most important independent work of this kind that is preserved is an anthology by Hala, called the *Sattasāi* (Sanskrit title *Saptasatī* "the 700 verses"); it was compiled between the 3rd and 7th centuries. Māhārāṣṭrī is the language of the lyric verses in the classical period of the Sanskrit drama beginning (in what survives to the present) with Kālidāsa. In this dialect there were also composed epics of the *kāvya* or belles-lettres type. The most important specimens are the *Rāvaṇavahā* or *Sētubandha* (attributed to Pravarasena, possibly 6th century A.D. dealing with the subject of the Rāmāyaṇa, and the *Gaudavaha* of Vākpati (8th century A.D.), celebrating the conquest of Bengal by Yaśovarman, king of Kanauj. Others exist, including the *Kumārāpālacarita*, or the last eight cantos of the poem *Dvyaśraya-mahākāvya* written by Hemacandra (12th century A.D.) to serve as a series of illustrations to his Sanskrit and Prakrit grammar, the *Siddha-hemacandra*. These

cantos in Prakrit illustrate the Prakrit section of the grammar.

The Sanskrit drama is an important source for knowledge of Prakrit. From its beginning its dialogue must have been intended as a realistic linguistic picture. In it educated men, like kings and Brahmins, spoke and also sang in Sanskrit, the literary language par excellence. All others, with few exceptions, spoke the vernacular; i.e., Prakrit. It must have been the case, however, that people of various classes or castes spoke differing dialects, and that people of different localities appeared in the plays speaking their own local dialects. By the time of the earliest specimens now preserved conventions had begun to harden, and by the time of the classical theatre of Kālidāsa and his successors various types of characters were always provided with dialogue in the dialects which were considered appropriate and which had taken on conventional, unchanging forms. Most women, if not of low caste, speak Śāurasenī, but sing in Māhārāṣṭrī; some children and various other characters, including the Brahmin clown, speak Śāurasenī. Various types of servants, fishermen, lowcaste men and many others speak Māgadhī. Other dialects appear in the drama. Unfortunately, after the grammarians had prescribed the forms of the dramatic Prakrits, the dramatists seem to have composed according to rule rather than from any real knowledge of the dialects as living forms of speech.

A Prakrit called Pāisāci is known through grammarians' statements. According to literary tradition it was the language in which Guṇādhyā's *Brhatkathā* was composed, before A.D. 500 and possibly in the 1st or 2nd century A.D. This work is known through much later reworkings, especially Sōmadēva's *Kathāsarit-sāgara* (11th century A.D.), but unfortunately the Pāisāci text has not yet come to light.

Of nonliterary materials in Prakrit there are early coin inscriptions and inscriptions on stone (3rd century B.C. to 4th century A.D.). Beside the inscriptions of Aśoka, which are the earliest, the most interesting are probably the materials from Niya in Chinese Turkestan. These are official documents from the Kroraina kingdom and date from the 3rd century A.D. Their Prakrit is close to that of the Dhammapada. The original home of the language was northwest India, probably the region of Peshawar; it seems to have been the administrative and literary language of the Kushan empire and its central Asiatic offshoots.

Some of the other Prakrits may be located geographically with some accuracy. Śāurasenī was the dialect of Śūrasēna, the country around Mathurā (Muttra). It was the language of the Gangetic Doab, and probably extended westward as far as Lahore and eastward as far as the confluence of the Jumna and the Ganges. Its use extended also to Rājputana and Gujarat. Māgadhī was spoken in the eastern half of the Ganges valley, extending westward probably as far as Varanasi (Benares). Māhārāṣṭrī was the language of Māhārāṣṭra, the "great Kingdom" south of the Nerubudda river, where in modern times Marāṭhī is spoken. Not all the dialects may be located with equal exactitude. Pāisāci, for example, may have been spoken in the northwest, although the Vindhya region south of the Ganges valley seems more probable.

Because of the literary pre-eminence of Māhārāṣṭrī, it is the Prakrit described at greatest length by the Indian grammarians, e.g., by Vararuci (before A.D. 700, perhaps much earlier) and Hemacandra (12th century A.D.). The other Prakrits used in the dramas, as well as numerous others which never appear in the literature, are described sketchily in terms usually of their deviations from Māhārāṣṭrī.

After various Prakrits had been given standard literary form, the vernaculars continued to diverge from these standards. Again at a later period various dialects received literary form; the earliest reference to a literary use of these seems to be in the 7th century A.D. They are known by the name *apabhramśa*, ("departure from correct speech"). One dialect, western *apabhramśa*, belonged to the region of Śāurasenī Prakrit, and is represented by numerous texts, most of them by Jain authors, such as Dhana-vāla's *Bhavisattakaha* (probably 10th century A.D.), Haribhadra's *Sanatkumāracaritam* (A.D. 1159), and Somaprabha's *Kumārāpāl-pratibodha* (A.D. 1195). There are also texts in a southern *apa-*

bhramśa, corresponding to Māhārāṣṭrī, and a few in an eastern apabhramśa, corresponding to Māgadhī.

The apabhramśa dialects are the immediate predecessors of the modern Indo-Aryan vernaculars, the older stages of which seem to have been recognized by the Indian grammarians as early as the 12th century A.D. The relations, however, between the various Middle Indic dialects and the modern languages are not yet clearly known in detail.

Characterization of the Languages.—The Middle Indo-Aryan languages are marked by progressive changes from the type of the Old Indo-Aryan languages. (Skt. = Sanskrit; Ś = Śaurasēnī; M. = Māhārāṣṭrī.)

Phonetic change is conspicuous. The complex consonant clusters of Skt. are simplified, most frequently by assimilations or losses, sometimes by insertions of vowels, e.g., *putra* "son" > *putta*, *ratna* "jewel" > Ś. *radana*, Māgadhī *ladana*. Stop consonants between vowels were liable to many sorts of changes. Voiceless stops (*k*, *t*, *p*) remained in Pali, became voiced (*g*, *d*, *b*) in some dialects, e.g., Ś and apabhramśa, but were lost in M., e.g., Skt. *śata* "100" > Pali *sata*, Ś. *sada*, M. *saa*. The cumulative effect of all changes was to produce words which are very far from their Skt. origins, e.g., Vappairā = Skt. *Vākpatirājā* "king Vākpati"; *prākṛta* "Prakrit" > Ś *pāūda*, M. *pūūa*.

Noun morphology tends toward simplification; e.g., by loss of the dual number. The eight-case system of Skt. is reduced by loss and amalgamation of cases. Dative forms are completely lost in some dialects; syntactically the dative merges with the genitive. In feminine stems in *ā*, the instrumental, genitive, and locative singular have identical forms. In the apabhramśa stage case declension had gone a long way toward the Modern Indo-Aryan system of practically only two cases, absolute and oblique. The system of three genders remains intact until in apabhramśa masculine and neuter came near to a complete merging. The numerous declensional types of Skt. are somewhat reduced in number. Especially, the consonant stems tend to add vowels and merge with the vocalic declensions.

Verb conjugation shows even greater departures from the Skt. system. With some exceptions, the Skt. consonantal conjugation has been replaced in Prakrit by the conjugation type in which a vowel appears between the final consonant of the root or stem and the inflectional suffix. In Middle Indo-Aryan the vowel is often *-a-* as in Skt., but there has been a great extension of use also of *-ē-*, which derives from *-aya-* of the Skt. causative and denominative conjugations. The causative stem on the other hand often has a suffix *-vē-*, in which *v* represents Skt. *p* which in Skt. appears in only a few verbs. Exceptional remnants of the Sanskrit consonantal conjugation include the highly irregular enclitic verb "to be", e.g., *mhi* "I am" (< *asmī*), *si* "you are" (< *asi*), etc.; the 3rd singular form *atthi* (< *asti*) is not enclitic. The past tenses are completely remade into one fairly well unified system in Pali, but in the Prakrit dialects very little remains of them, except such forms as *āsi* "was, were" (< *āsīt*). The present tense has an imperative and an optative. The future remains, usually formed with a suffix *-issa-* or *-ihi-* (< Skt. *-iṣya-*) added to the present stem. Passive stems either derive from Skt. passive stems, with Skt. *-y-* appearing in M. as *-jj-* (e.g., *dijjāi* "it is given" < Skt. *diyate*), or add a suffix (Ś *-ia-*, M. *-ijja-*) to the present stem. Infinitives, gerunds, gerundives and present participles all survive from Skt., with many phonetic and other changes. Most important is the past participle, which is passive in transitive verbs and active in intransitive verbs. Syntactically, it occurs most frequently with an instrumental case of a noun, to replace the old past tense and its subject; this is the precursor of the peculiar past tense of Modern Indo-Aryan. Very frequently the past participle shows a suffix Ś. *-ida-*, M. *-ia-* (< Skt. *-ita-*) added to the present stem. This part of the verb system shows more irregularities of form than any other, because of inheritance of old forms from Skt., e.g., Ś. *gada-*, M. *gaa-* "gone" (< Skt. *gata-*) beside present stem *gacch-*; Ś. *kida-*, M. *kaa-* "made" (< Skt. *kṛta-*) beside present stem *kar-*; Ś. *nāda-*, M. *nāa-* "known" (< Skt. *jñāta-*) beside present stem *jān-*.

The vocabulary of Prakrit is in general derived from Old Indo-

Aryan, but there are also many words not so derivable, called *dēśi* or "provincial" words. Lists of these were produced by the Indian grammarians.

Pandit, *The Gaṇḍavaho by Vākpati* (1887) and *The Kumārāpālāchārī* (1900). (M. B. E.)

PRAKRIT LITERATURE. The greatest contribution to Prakrit literature was made by the Buddhists, who wrote in a Prakrit language called Pali; their writings are described in the article PALI LITERATURE. This article discusses the literature that was written in Prakrits other than Pali (see PRAKRIT LANGUAGES) and which is chiefly important as the literature of Jainism (q.v.).

Canonical Literature.—The canon of the Śvetāmbaras (Shvetambaras), one of the two Jain sects, is composed entirely in Prakrits. It was fixed in its present form by the 6th century A.D., although some portions may date from the 3rd century B.C. It contains a mixture of monastic rules, dogmatics, philosophy, cosmology, gnomic sayings, folktales, encyclopaedic enumerations and legends about Jain devotees. Its literary value varies greatly and some of the older texts, such as the *Āyāraṅga*, *Sūyagadāṃga*, and *Uttarajjhayaṇa-sutta*, sometimes reach a high poetic standard while others, such as the *Anuttaravavāīya-sutta*, consist of little more than a series of stereotyped accounts of how devotees starved themselves to death.

The earliest commentaries on this canon, the *nijjuttis*, *cūmā*, and *bhāṣyas*, are written in a Prakrit, and are noted for the wealth of ancient historical and semihistorical tradition and the mass of folktales they contain. Many of these Prakrit stories are incorporated in the later Sanskrit commentaries of Haribhadra (5th century) and Devendra (11th century).

The early quasi-canonical texts of the other Jain sect, the Digambaras, were also written in a Prakrit and are mainly on philosophical and polemic themes. One of the earliest Digambara authors is Kundakunda (perhaps 1st century A.D.), whose works include the *Pavayanāsāra*, *Samayasāra*, and *Niyamasāra*. Later Digambara philosophical writings include the *Yogasāra* and *Pārśva mātmaprakāśa* by Yogindra (6th to 10th century).

Narrative Literature.—There is a rich Prakrit narrative literature, for the Jains appropriated many of the themes of the common Indian literary inheritance for their own religious purposes. The earliest Prakrit epic is probably the *Paumacariya* of Vimala Sūri (perhaps 3rd or 4th century A.D.), based largely on Valmiki's *Rāmāyaṇa* (see SANSKRIT LITERATURE). Other versions of the Rāma story are the *Vasudevahindī* of Saṅghadeva (before the 7th century), the *Paumacariya* of Svayambhū (before the 10th century), and the *Mahāpurāṇa* of Puṣpadanta (10th century). The authors' claim to be great epic poets is not entirely unjustified, for they show an ability to compose in a highly ornate style, based on Sanskrit models. Their main aim, however, is not literary but religious, and their narrative is often interrupted by long instructive discourses on religion and morality. The protagonists are finally converted to Jainism and attain *nirvāṇa*.

The *Mahābhārata* (q.v.) story is similarly adapted for Jain purposes. Portions of the story are already found in the Śvetāmbara

canon, but the earliest Jain version of the story as a whole is the *Harivamsapurāṇa* of Jināsena (8th century). Non-Jain epics include the *Rāvaṇavahā* by Pravaraśena (perhaps 6th century) which is based on the Rāma story, and the *Gāṇḍavahā* by Vākpati (8th century), which relates the story of the conquest of Bengal by Yaśovarman, king of Kanauj.

The *kathānakas* ("minor stories"), of the type found in the commentaries on the canon, also exist as separate works. These are stories of a more popular nature, intended both to instruct and to amuse, and their language is usually simple, with occasional passages of high-flown poetic imagery. The *dharmakāhās* ("religious stories"), such as the *Samarāścakāhā* by Haribhadra and the *Bhavisattakāhā* by Dhaṇavāla (perhaps 10th century), differ from this more popular literature in being more pretentious and aiming at a more poetic style.

Jain Prakrit literature is rich in hagiographical works. Lives of the *tīrthāṅkaras* (or *jinas*), the 24 spiritual conquerors, appear in the canon, and later formed the subject of independent works called *cariyas*. The *Cauppanṇamahāpurisacariya* of Śilāṅka (9th century) is a collection of biographies of the *jinas* and other heroes. Biographies of individual *jinas* or other Jain personages include the *Jasaharacarīya* of Puṣpadanta and the *Karakaṇḍacarīya* of Kanakumāra (11th century). A nonreligious work of this type is the *Kumārāpālacarita* by Hemacandra (12th century), written to illustrate the rules of his Prakrit grammar while describing the achievements of his royal patron Kumārāpāla.

Didactic, Dramatic, and Technical Literature.—Didactic poetry has a prominent place in the Jain canon, but of noncanonical works the *Uvaśamāla* by Dharmadāsa (before the 9th century) is probably the oldest. The *Kumārāpālāpratibodha* by Somaprabha (12th century) is a didactic poem which includes a collection of tales reputedly used to illustrate the sermons by which Hemacandra converted Kumārāpāla to Jainism.

Dramatic works were mainly written by non-Jains. In the earliest extant dramas, those of Aśvaghōṣa (perhaps 1st century A.D.) and Bhāsa (perhaps 2nd century A.D.), the humbler characters already speak in various Prakrits (see SANSKRIT LITERATURE: Drama). Kālidāsa (q.v.; fl. c. 400) seems to have been the first to use Māhārāṣṭrī Prakrit in a play, possibly introducing it from lyric poetry where its long-established use is shown by the anthologies, in particular the *Sattasāi* of Hāla (3rd to 7th century), and the *Vajjālagga* of Jayavallabha (8th to 13th century). Dramas were sometimes written in which all characters, even the king, spoke in a Prakrit; e.g., the *Karpūramañjarī* by Rājāśekhara (perhaps 9th century).

The considerable amount of technical literature written in various Prakrits includes the cosmological works *Tiloyapaṇṇatti* of Jadvasaha (5th to 7th century) and *Jambudīpapaṇṇattisaṃgaha* of Pūmanandī (perhaps 11th century). Grammars of Prakrit include the *Prākṛtaprakāśa* of Vararuci (before A.D. 700), the *Prākṛtalakṣaṇa* of Caṇḍa (of unknown date) and the eighth chapter of the *Siddha-hemacandra* of Hemacandra. The grammarians also compiled dictionaries of *deśī* words (i.e., those not derivable from Sanskrit). These include the *Pāyīlacchīnāmamālā* of Dhaṇavāla (10th century) as well as the *Deśīnāmamālā* of Hemacandra.

The Last Stages of Prakrit.—After the 12th century Prakrit began to develop into the New Indo-Aryan vernaculars, and Prakrit literature shows signs of this change (see INDIAN LITERATURE). It is debatable whether such a work as the *Kīrtīlātā* of Vijjāvai (14th century), which presents a form of Apabhraṃśa influenced by the developing Maithilī vernacular and strewn with Arabic and Persian words, is to be considered as Prakrit literature or not. Nevertheless, some authors continued to write technically correct examples of Prakrit composition according to the rules laid down by grammarians hundreds of years before. The last period of Prakrit literature includes such works as the drama *Candralekḥā* of Rudradāsa (17th century), in which all the characters speak in Prakrits, and the epic poems *Kaṃsavahā* and *Usāṇīruddha* of Rāma Pānīvāda (18th century).

BIBLIOGRAPHY.—Extensive bibliographical references to Jain canonical and noncanonical literature are given by M. Winternitz, *History*

of Indian Literature, vol. 2 (1933), and W. Schubring, *Die Lehre der Jainas* (1935). Other editions of Prakrit works include *Two Prakrit Versions of the Manipāṭīcarita*, ed. by R. Williams (1959), and publications in the *Singhi Jain Series* (Bombay, 1936–), *Jīvarāja Jaina Granthamālā* (Sholapur, 1951–), *Prakrit Text Society Series* (Varanasi, 1957–) and other series. See also the bibliography for PRAKRIT LANGUAGES.

PRANDTL, LUDWIG (1875–1953), German physicist famous for his work in aeronautics, was born at Freising, Bavaria, on Feb. 4, 1875. He qualified at Munich in 1900 with a thesis on elastic stability, and was professor of applied mechanics at Göttingen from 1904 until his death there on Aug. 13, 1953. In 1925 he became director of the Kaiser Wilhelm Institute for fluid mechanics. His discovery (1904) of the "boundary layer" which adjoins the surface of a body moving in air or water led to an understanding of skin friction drag and of the way in which streamlining reduces the drag of airplane wings and other moving bodies. His work on wing theory, published in 1918–19, which followed that of F. W. Lanchester (1902–07) but was carried out independently, elucidated the flow over airplane wings of finite span. This body of work is known as the Lanchester-Prandtl wing theory (see AERODYNAMICS).

Prandtl made decisive advances in boundary layer and wing theories, and his work became the basic material of aerodynamics. He also made important contributions to the theories of supersonic flow and of turbulence, besides contributing much to the development of wind tunnels and other aerodynamic equipment. In addition he devised the soap-film analogy for the torsion of noncircular sections and wrote on the theory of plasticity and on meteorology. (H. B. S.)

PRASEODYMIUM is a moderately soft, silvery metal of the rare-earth (q.v.) group. It is oxidized slowly by air at room temperature and reacts rapidly with hot water, liberating hydrogen. The metal is a component of Misch metal (see CERIUM), which is used for cigarette lighter flints and as an alloying addition in magnesium alloys of high strength and creep resistance used principally for jet engine parts. (The use of an alloying constituent consisting primarily of praseodymium and neodymium in place of Misch metal gives a magnesium alloy of still higher strengths at all temperatures.) A mixture of praseodymium and neodymium is used as colouring in the goggles worn by glassblowers and welders. Praseodymium oxide is used to produce a yellow ceramic colour on a zirconium oxide base. The element was discovered by C. A. von Welsbach in 1885 when he separated a "didymium" salt fraction into praseodymium and neodymium. The name is a shortened variant of *praeseodidymium* ("green didymium," from the green colour of the salts). Praseodymium occurs in many rare-earth minerals; the chief commercial source is monazite (q.v.). It is also one of the products of atomic fission. Praseodymium may be separated and purified by fractional crystallization and precipitation, but ion-exchange techniques have been used since World War II for commercial production.

The symbol of praseodymium is Pr; atomic number 59; atomic weight 140.907. (Ld. B. A.; J. B. Ps.)

PRATAPGARH (formerly PARTABGARH), a town and district in the Fyzabad division of Uttar Pradesh, India. The town, headquarters of the district, lies about 25 mi. (40 km.) N of Allahabad, on the Varanasi-Lucknow railway.

PRATAPGARH DISTRICT (area 1,458 sq.mi. [3,776 sq.km.]; pop. [1961] 1,252,196) lies in the southeast of Uttar Pradesh with the Ganges forming its southwestern boundary. The general aspect of the district is that of a richly wooded and fertile plain, relieved by gentle undulations and ravines near the rivers and streams. Smallish barren tracts impregnated with saline efflorescence (reh) occur in places. The only mineral products are salt, saltpetre and *kankar* (nodular limestone). Main crops are rice, barley, pulse, millets, and sugar cane; hemp and hides are also produced.

PRATAPGARH is also the name of a town in Chittorgarh district of Rajasthan, India, and of a former princely state. The walled town lies 75 mi. (121 km.) SE of Udaipur. Pop. (1961) 14,573. It was founded in 1698 by Maharawat Pratap Singh and became the capital of the princely state, which was once tributary to Indore (Holkar). It came under British protection in 1818 and

was merged with Rajasthan in 1948. The people are mostly Bhils and other aborigines (*see* BHIL). Pratapgarh was once well known for its engraved gold enameled work inlaid on emerald-coloured glass. (S. M. T. R.)

PRATINAS (fl. c. 490 B.C.), Greek poet of the Dorian city of Phlius, who brought his satyr plays to Athens and was reckoned as the inventor of this kind of drama. He composed tragedies also, but of the 50 plays claimed for him by the Suda lexicon 32 were satyric, which may indicate that he began to produce before the competition was organized in tetralogies, including one satyr play. His son Aristias competed in 467 with a set of Pratinas' plays, so that Pratinas probably died shortly before that date. Unfortunately nothing of his plays survives. Athenaeus quotes a hyporcheme of his (a type of lyric sung by a chorus to the accompaniment of vigorous dancing), which gives a fine impression of his lyric powers: the chorus energetically overwhelm their overpretentious flute player and teach him his place, as their accompanist. This is often stated, against Athenaeus' explicit evidence, to be a fragment of a satyr play. (A. M. DE.)

PRATO (PRATO IN TOSCANA), a town of the Province of Firenze, region of Tuscany, central Italy, lies on the Bisenzio River at the foot of the Monti della Calvana, 10 mi. NW of the city of Florence. It is the seat of a bishopric. Pop. (1961) 111,112 (commune). Old Prato, which is still surrounded by a wall (c. 1330), has narrow streets with many medieval buildings. Outstanding is the cathedral, a harmonious fusion of Romanesque and Gothic; the nave, by Guidetto (begun 1211), is the Romanesque portion and the transepts (1317–20, perhaps by Giovanni Pisano) the Gothic portion. The campanile is 13th–14th century. The facade is adorned with a splendid pulpit (1434–38) by Donatello and his partner Michelozzo. Interior works include the frescoes of Filippo Lippi in the choir (1456–66). Another church, one of the finest of the Tuscan Renaissance, is Sta. Maria delle Carceri (1485–92), the masterpiece of Giuliano da Sangallo. The 13th-century Castello dell' Imperatore was built by the Holy Roman emperor Frederick II. Notable also is the 18th-century Collegio Cicognini. The town has modern and expanding suburbs.

Prato is connected by rail with Florence, Pistoia, and Bologna, and is served by the Florence-coast motorway. It is a leading centre for wool manufacture, which has been traditional to it for many centuries. Textile machinery and cement also are made.

The origin of Prato is uncertain. It became a free Italian commune in the 11th century; was later drawn into the orbit of Florence (which succeeded in purchasing its overlordship despite the famine and plague of 1347–48); and was brutally sacked by the Spanish Army in 1512 during the campaign to restore the Medici. In 1653 it obtained the rank of city. Prato's subsequent existence was uneventful, until, in the 19th century, it became a lively centre of political activity during the Risorgimento. (G. N.)

PRATT, EDWIN JOHN (1882–1964), the leading Canadian poet of his time, was born at Western Bay, Nfld., on Feb. 4, 1882, the son of a Methodist clergyman. After a preparatory education in Newfoundland and some experience in teaching, he went to Victoria College in the University of Toronto, where he graduated in 1911. He then studied theology and published, in 1917, *Studies in Pauline Eschatology* (developed from his Ph.D. dissertation), but his academic interests turned to psychology—he was for several years a psychologist on the staff of the university—and finally to English literature, which he taught at Victoria College from 1919 until his retirement as professor emeritus in 1953.

His first collection of poems, *Newfoundland Verse* (1923), drew on his early impressions, especially of the hardships and courage of the fishermen in their constant battle with the sea. Even when lyrical, the poems show an interest in and a distinctive command of the techniques of narrative, to which Pratt turned in *The Witches' Brew* (1925) and *The Titans* (1926), the second of which is made up of two long poems, "The Cachalot," and "The Great Feud." "The Cachalot," an account of a whale hunt, is one of his most brilliant and widely read poems. All three are in octosyllabic couplets, and show a lively humour and the free play of an exuberant imagination that marked Pratt out as a strikingly

original poet in a quite new genre. Pratt's fascination with themes of shipwreck broadened and deepened in *The Roosevelt and the Antiope* (1930) and *The Titanic* (1935), where a more sombre sense of the indifference of nature to human values prevails.

With *Brébeuf and His Brethren* (1940), a blank-verse chronicle of the martyrdom of Jesuit missionaries by the Iroquois, Pratt was established as Canada's most influential poetic personality. (For the importance of his influence *see* CANADIAN LITERATURE [ENGLISH]). Three volumes after *Newfoundland Verse* contain the bulk of his shorter poems: *Many Moods* (1932), *The Fables of the Goats and Other Poems* (1937), *Still Life and Other Verse* (1943). Many of these poems are still concerned with the sea and seafaring life, but there is a growing awareness of the poet's social responsibilities, reflected in the title poem of *Still Life*, in some bitter anti-Nazi satire, and in some philosophical verse, notably *The Iron Door* (1927) and the remarkable dialogue "The Truant" in *Still Life*.

After the outbreak of World War II, Pratt turned mainly to topical themes, especially in *Dunkirk* (1941). His *Collected Poems*, with a preface by William Rose Benet, appeared in 1944 (U.S. edition, 1945; 2nd ed., 1958). *Behind the Log* (1947) commemorates the heroism of the Canadian convoy fleet in running supplies to Murmansk through the war, and *Towards the Last Spike* (1952) tells of the building of the Canadian Pacific Railway (1870–85). Many features of Pratt's work made him not simply a respected but a genuinely popular poet in Canada: his preoccupation with the Canadian scene, both historical and geographical; his power of storytelling; his unforced use of the imagery of machinery and technology.

Pratt was awarded the highest civilian honour in Canada, the companion of the Order of St. Michael and St. George, in 1946, and received many honorary degrees from Canadian universities. He died in Toronto on April 26, 1964.

PRAXITELES, of Athens, greatest of the Attic sculptors of the 4th century B.C., was active from perhaps c. 370 B.C. to 330 B.C. Ancient writers sing his praises, and they are borne out by what would seem to be the only major original work that has survived, i.e., the marble statue of Hermes carrying the infant Dionysus. It was found at Olympia in the temple of Hera, in the very place where it was seen and described by Pausanias (v, 17, 3). The delicate modeling and exquisite finish of the surface enable one to add these qualities to one's imagination to the other works by him that exist only in Roman copies. His most celebrated work was the Aphrodite which he made for Cnidus, considered by Pliny not only the finest statue by Praxiteles but in the whole world. Numerous copies have been recognized—statues, heads and statuettes—in the Vatican and in the Terme museum in Rome; in the Louvre, Paris; at Toulouse; etc.).

Many other statues, both in marble and bronze, are mentioned by ancient writers as works by Praxiteles, but comparatively few have been identified in Roman copies. Chief among them are: the Apollo

"APHRODITE OF CNIDUS" BY PRAXITELES: A ROMAN COPY IN THE VATICAN MUSEUM

Sauroctonus, in which the god is shown as a boy leaning against a tree trunk, about to kill a lizard with an arrow; the Artemis Brauronia perhaps reproduced in the charming Artemis of Gabii in the Louvre; and several Erotes and Satyrs.

Two sculptures that can be connected with Praxiteles stand apart. One is a base decorated with Marsyas and the Muses described by Pausanias as in a temple at Mantinea and supporting the statues of Leto, Apollo and Artemis by Praxiteles. Three slabs of this base have actually come to light, and, though probably not executed by Praxiteles himself, for the execution is cursory, they presumably reproduce his design. The other work is the bust of a youth, found at Eleusis. It seems to be an original Greek work of the 4th century and has by some been thought to be the Eubuleus known to have been made by Praxiteles. It approximates, though it does not equal, the workmanship of the Hermes.

According to Pliny, when Praxiteles was asked which of his statues he valued most highly, he replied "those to which Nicias (a famous painter) has put his hand; so much did he prize the application of colour (circumlitio) of that artist." To visualize the sculptures of Praxiteles it is well to remember how much this colour must have added to the general effect.

Praxiteles was one of the most original of Greek sculptors. He transformed the 5th-century style of detachment and majesty into one of gentle grace and sensuous charm. His favourite material was marble, of which he was perhaps the greatest exponent. Diodorus says of him that "with consummate art he informed his marble figures with the passions of the soul." It is indeed this subtle, personal element, combined with an exquisite finish of surface, that imparts to his figures their singular appeal.

The influence of Praxiteles was widespread. Figures standing in graceful, sinuous poses and lightly leaning on some support became favourite representations and were later further developed by the sculptors of the Hellenistic age. See also GREEK ART.

PRAYER, man's personal directing of himself toward and intercourse with the transcendental reality, whether in word or in thought. Many theologians and scholars of comparative religion regard prayer as the central phenomenon of religion, a position others claim is held by sacrifice (*q.v.*). These two views can be correlated by pointing out that at its highest level sacrifice is absorbed into prayer, insofar as sacrificial giving of oneself to God takes place spiritually by means of prayer.

Private Prayer.—At its lower levels prayer is closely related to spells or incantations, from which it must be carefully distinguished. Incantation may be regarded as the mere expression of a wish; it appears in various forms as a blessing (a good wish), a curse (an evil wish), or an oath (a conditional curse which is to recoil on the maker if it later appears that he has lied or broken faith). All incantations, however, are meant to have their effect without the help of a superhuman being. Prayer, on the other hand, even in its primitive form, is addressed to another being, who is considered to be in some sense personal, or similar to man, on whom man knows he depends, and whom man regards as on the whole kindly disposed to him and ready to help, though sometimes angry. Somewhere between prayer and incantation lies conjuration, whereby some fundamentally evil and hostile spiritual being is compelled either to appear or to depart.

Communication with divine beings in prayer is carried on in the same way as ordinary social intercourse, whether the divine being is a natural force (e.g., a rain god), a patron of human activity (e.g., a goddess of childbirth), an ancestor, or the highest power of all, the god of heaven and the creator. Thus the terms of address "Father," "Mother," "Lord," "King," are used in prayer, as are such forms of speech as confession of sins, requests, thanks, praise, reference to presents (sacrifice), or the promise of presents (a vow) if a request made in prayer is fulfilled. In all these ways man tries to influence the deity: to win him over, to change

his mind, or to appease him. A characteristic feature of prayer at its primitive level is the desire to be free from earthly ills and dangers and to gain earthly goods.

As a blessing or a curse can be approximated to a prayer ("May God bless" or "curse so-and-so"), so conversely on the primitive level prayer takes on forms similar to magical formulas or to oaths when it is thought of as having magical or compulsive power. This combination of the personal address to a divine being with impersonal magic is apparent also in the bodily attitudes (standing, kneeling, crouching, prostration) and position of the hands (raised, folded, crossed, clasped) of the person praying. Such attitudes too have a social character, for they express submission, homage, and devotion, while at the same time, because of their disarming nature, they are a defense against a taboo or against a danger from the superhuman being.

This primitive prayer, whose simple forms are found among preliterate peoples, lived on into the ancient civilizations, where it developed from its spontaneous and free expression into fixed formularies. Another development was the hymn, which gradually escaped from ritual rigidity and formality into pure contemplation of God's working in nature and reached its highest point in the hymns to the sun of the Egyptian king Ikhnaton.

Prayer, directed to a person, seems to have originated independently of magic, which is wholly impersonal, although their paths perpetually crossed and indeed intermingled as they developed. The common assumption that magical formula preceded prayer and that prayer owed its origin to a failure in magic cannot be proved.

As religion became more spiritual and moral, man's prayer life developed comparably. Requests for earthly goods assumed much less importance and in some cases disappeared completely, while prayers for spiritual and moral qualities, for the knowledge and love of God, and for union with him, came to the fore. Confession of sin, praise and thanksgiving, expressions of trust and acceptance of the will of God, also predominated. Whereas in primitive prayer man with his needs and desires puts himself at the centre, in higher forms of prayer God is at the centre. "You shall pray for nothing else than God himself," warns St. Augustine. Further, prayer expressed in words is replaced by wordless prayer, called "spiritual prayer" or "prayer of the heart," the holy silence, which mystics experience as the purest form of reverent adoration of the deity. For great religious figures, whether mystics, prophets, apostles, or reformers, prayer is not only a regular turning to God but it becomes their whole life ("Pray constantly"; I Thess. 5:17). St. Francis of Assisi is said by his biographer Thomas of Celano not so much to have prayed as to have turned into prayer. Above all, prayer is regarded as a gift of grace from God, not as an independent activity of man: "we do not know how to pray as we ought, but the Spirit himself intercedes for us with sighs too deep for words" (Rom. 8:26).

This higher form of prayer is found in Judaism, Christianity, Islam, Buddhism, Brahmanism, and Hinduism. In all these religions, but particularly in the first three, two types of prayer appear side by side. One is a simple, spontaneous "outpouring of the soul" (e.g., in Ps. 42:4, and in many other Old Testament passages). The other is more elaborate, frequently marked off in ascending steps, and described with psychological accuracy. The goal of this second type is mystical union, whether this is thought of as leading to identity of the worshiper with the deity or as a spiritual marriage between them. Such mystical prayer is often connected with a material pledge of the divine presence, as for instance the images of gods in Buddhism and Hinduism and the Eucharist and icons in Christianity. In earlier Buddhism, which had no real concept of God, absorption into one's own inner being in meditation and contemplation takes the place of the mystical "prayer of the heart." Although in Buddhism in its original form this prayer is not directed toward a personal deity, its aim is Nirvana, which is not only the state of deliverance but also a mystical "highest good."

Communal Prayer.—Public as well as private prayer is found at all stages in the development of religion. Among primitive peoples communal prayer takes the form of responses by the com-

munity to the prayers of their representative, who may be the head of a household, a chieftain, or a priest (see **PRIESTHOOD**). The most elaborate development of such communal prayer is found in Judaism after the destruction of the Second Temple (A.D. 70) and in Christianity, which carried on the Jewish tradition. Prayer in public worship is, first and foremost, praise of God for the creation and for the redemption. The highest point of such praise in Christian worship is the preface in the Eucharist, which is introduced by the dialogue "Lift up your hearts . . ." between priest and people and concludes with the threefold *Sanctus* ("Holy, Holy, Holy . . .") taken from the Jewish Temple liturgy (Isa. 6:3). (See further **LITURGY**.)

After praise comes intercessory prayer for the needs of God's people and of all mankind. The apogee of communal prayer is the Lord's Prayer (*q.v.*), which combines the chief petitions used by Jesus' Jewish contemporaries. Its central feature is the prayer for the coming of the Kingdom of God. A parallel prayer in Buddhism is the following: "May every living thing, movable or unmoving, tall, big, or medium-sized, clumsy or refined, visible or invisible, near or far, already born or aspiring to birth—may all beings have a happy heart."

Obligatory Prayer.—The four prophetic religions, Judaism, Christianity, Islam, and Zoroastrianism, teach the observance of a daily set form of prayer for certain individuals, in addition to spontaneous private prayer and public worship in common. Every male Jew must twice a day recite the Shema, the commandment to love Yahweh as the only true God ("Hear, O Israel . . ."; Deut. 6:4), and the so-called Prayer of 18 Requests ('Amida), also simply called "prayer" (Tefilla), which combines praise, thanksgiving, and petition. The latter must be recited three times a day by women, slaves, and children, as well as by men. (See also **LITURGY, JEWISH**.)

The canonical hours of the Christian Church, which developed out of these obligatory Jewish prayers, are said or sung communally by monks and nuns in convent chapels and said privately by secular priests (see **HOURS, CANONICAL**). In the Anglican Communion and in Lutheran churches a simplified form of the canonical hours is used as a congregational service (see **COMMON PRAYER, BOOK OF**).

The Islamic *salat*, more closely related to the obligatory Jewish prayers, is performed five times a day (at dawn, at midday, in the afternoon, immediately after sunset, and about two hours later) after the call to prayer made from the minaret. Ritual ablutions take place before the prayer. Strict regulations govern both the recital of the texts (the first *sura* of the Koran, a prayer of praise, a confession of faith, a benediction of the prophet and the faithful) and the bodily postures (standing, bowing, prostration, crouching, raising or stretching out the hands, etc.). Similar recitations of formulas take place in Zoroastrianism (see **PARSEES: Ritual**). In all these religions, further, the repetitions of obligatory prayer formulas are regarded as particularly meritorious.

Philosophical Problems.—The philosophical problems raised by prayer were seriously studied in the ancient world, and this criticism has been further developed by modern philosophers. Any prayer for earthly good fortune seems to the philosopher unworthy of address to God. In particular, the idea that man's prayers can influence God seems incompatible with a philosophical conception of the deity. This criticism of course concerns only the lower forms of prayer, not mystical prayer or the classical Christian theories of prayer. The early Christian theologian Origen said that to pray for earthly things was disobedience to God. Augustine pointed out that prayer was intended not to instruct God but to elevate man, not to make God change his mind but to bring man round to what he ought to desire. Prayer for Thomas Aquinas is concerned only with awaking trust in man and with contemplation of God's love. Meister Eckhart regards each prayer as a part of the eternal foresight of God and of his eternal predestination.

The philosophical problems of prayer have become more involved since the advent of modern astronomy, which has no place for a heavenly ruler enthroned high above the earth but only for the creative force which permeates the immeasurable universe. This cosmic viewpoint had been anticipated by the mystics' con-

cept of infinity, though the mystics always stressed the immanence of God as well as his transcendence. (See **MYSTICISM**.) Thus, the infinitely great God of the cosmos dwells in the heart of man; not only can he hear man's cry but this cry is but the echo of the call of God that preceded it; however many desires expressed in prayer remain unfulfilled, the faithful believer knows that no prayer goes unheard. The Islamic poet Jalal-ud-din Rumi tells in his *Mathnawi* (2:195–197) how a bewildered man complained that when he cried "O God" God did not reply "Here am I"; and how he then received from God this consoling revelation: "That 'O God' of thine is my 'here am I' and that supplication and grief and ardour of thine is my messenger to thee. Thy shifts and attempts to find a means of gaining access to me were in reality my drawing thee towards me. . . . Thy fear and love are the noose to catch my favour: beneath every 'O Lord' of thine is many a 'Here am I' from me" (Eng. trans. by R. A. Nicholson, ed., *Mathnawi*, vol. 2, 1926).

PRAYING MANTIS: see MANTIS.

PREACHING, a term popularly applied to any type of authoritative moral exhortation. Even in its ecclesiastical sense and in its Christian form, which alone is considered in this article, it is not patient of clear and precise definition. It will be convenient to start from the distinction indicated by New Testament scholars between *kerygma* and *didache*, proclamation and instruction. First the gospel must be proclaimed or preached; then the catechumen must be instructed in the Christian tradition and the Christian way of life. "Preaching" is thus distinguished from "teaching." But in practice the distinction wavers, for preaching is undoubtedly a form of instruction, and instruction in Christian doctrine or Christian practice may often in fact, if not in form, be preaching.

The distinction is parallel to that in the Old Testament between the functions of the prophet and the priest. The prophet from his own insight or inspiration says, "Thus says the Lord"; the priest gives instruction in the Torah, the tradition. But, again, the distinction is not absolute. The Book of Deuteronomy, for instance, is part of the Torah, the Law, but it is also prophetic literature. It is teaching quickened by prophetic insight.

History.—The New Testament contains much catechetical instruction, but the ground plan of the apostolic preaching (*kerygma*) is not in doubt:

The prophecies of the Old Testament have now been fulfilled. This has happened in the ministry, death and resurrection of Jesus. He has now been exalted to God's right hand as Messiah and Lord. This

belief has been confirmed by the gift of the Holy Spirit. Jesus will return to bring God's purposes to their consummation. Meanwhile men have an opportunity to repent and to receive forgiveness and the gift of the Holy Spirit (pp. 37-38 from *The Apostolic Age*, by G. B. Caird, Gerald Duckworth & Co. Ltd., London, 1955).

The primitive church distinguished between the offices of prophet and of teacher (cf. Eph. iv, 11). "Prophecy" roughly corresponded with "preaching." But soon, under stress of pressures from within and without, "prophecy" fell into disfavour, and charismatic ministries came to be regarded with suspicion. The bishop was designated the guardian of the apostolic tradition, and "preaching" gradually gave place to "teaching," a function of officials.

At the Eucharist in the 2nd century, as Justin Martyr says, after the reading of the memoirs of the apostles and the writings of the prophets the president gave "the instruction and exhortation (*nouthesian kai paraklesin*) to the imitation of these noble things." This must presumably have been teaching rather than preaching; the evangelistic or missionary work of the church must have been in the hands of laymen such as Justin himself. In those days the purpose of philosophy was deemed to be "the salvation of the soul," as the Neoplatonist Porphyry says, and Justin was the Christian philosopher comparable to the Stoic and Cynic preachers of the day.

In the early days of eastern Christianity there were notable preachers such as Gregory of Nazianzus and Basil in the 4th century and Theodoret in the 5th. But after the Council of Chalcedon (451) preaching became largely a matter of compilation and quotation concerned with asceticism, legends of the saints, angels, the cult of the Virgin Mary, icons and the like. A notable exception was Simeon the New Theologian (9th-10th centuries), but even he addressed almost exclusively a monkish audience. The reasons for this are twofold. On the one side was the pressure of the imperial interest and later of Islam. On the other was the nature of the Orthodox liturgy; for whereas rhetoric was widely studied in the Byzantine empire, in respect of worship "we do not consider God, we experience him." In the 20th century a revival of preaching has occurred in Orthodox churches, but the relative disparagement of preaching continues because of the view that the central rite of the Eucharist is itself the proclamation or preaching of the gospel.

With the collapse of the western Roman empire and the irruption of the barbarians, preaching, apart from cloistral meditations given to monks and nuns, became largely a fierce denunciation of sin and a threatening of hell-fire. Certainly the "preaching" of the crusades cannot be regarded as a republication of the apostolic gospel. But in the west during the 11th and 12th centuries, after the foundation of the Franciscan and Dominican preaching orders, there was a notable revival of preaching, and vast crowds gathered to hear the preachers.

At the end of the middle ages in the west there was a sad decline of preaching into the burlesque-scholastic, but with the Reformation came a great revival. This was inevitable, for *verbum, inquam, et solum verbum, est vehiculum gratiae*, said Luther: "The Word, and the Word alone, is the vehicle of grace." Sacrament and sermon were the two modes of the operation of the Word, but there was to be no sacrament without the preaching of the apostolic gospel.

Within the Roman Catholic Church there was a revival of preaching also. The Council of Trent laid great stress upon the importance of frequent preaching; Charles Borromeo, himself a famous preacher, set up a school of preaching in Milan in the 16th century, and there were many notable Roman Catholic preachers, such as François Fénelon and Jean Baptiste Massillon in the 17th-18th centuries.

In the Anglican Church the sermon, on the whole and with many notable exceptions, has conformed to the type of homily or pastoral teaching rather than the proclamation of the gospel. This is, perhaps, connected with the transference of the sermon from the communion service, where it belongs in the Book of Common Prayer, to the noneucharistic offices of matins and evensong. In the Reformed churches which stem from Geneva public worship is in principle eucharistic even where there is no celebration of

the Supper. According to the theory of these churches, therefore, the sermon is, as it were, the monstration in which Christ is held up before the congregation for their worship and adoration; it is the counterpart of "the breaking of the bread" and its distribution to the congregation. While, in fact, many Anglicans preach powerfully in the full sense of *kerygma* or the apostolic gospel, and many representatives of traditional Protestantism emit sermons which barely fall under the category of *didache* or teaching, the concept of the sermon and of preaching differs in these two traditions.

Types of Preaching.—It would be both tedious and invidious to attempt a catalogue of the most famous preachers, but powerful sermons fall into several overlapping categories, which may be illustrated by an almost arbitrary selection of great names.

First, there are the natural orators such as John Chrysostom, bishop of Constantinople in the 4th century, whose eloquence was such that he had to deprecate the applause he often elicited from his congregation; the 17th-century French bishop J. B. Bossuet; his contemporary Isaac Barrow, the preceptor of Isaac Newton and master of Trinity college, Cambridge, who has been styled "the English Bossuet"; the 18th-century George Whitefield, of whom the orator Bolingbroke wrote, "He has the most commanding eloquence I ever heard in any person" and of whom Hume said that it was worth going 20 miles to hear him preach.

But of these Chrysostom was an expositor of Scripture; Bossuet's most famous sermons are rather panegyrics upon the dead than declarations of the gospel; Barrow was at different times professor of Greek, of geometry and of mathematics; and Whitefield was an itinerant preacher of the gospel. If the excellence of preaching be judged by its effect, a sermon cannot be estimated by the oratorical prowess of the preacher or the literary felicities of his manuscript. One may criticize the style or content of J. H. Newman's Anglican sermons and wonder why they have been so extravagantly praised, but there can be no doubt about the profound impression they made upon the hearers. Indeed, many a sermon imperfect in literary form and unsatisfactory in logical presentation has achieved greatness because its conclusion, driven home by the earnestness of the preacher and some divine concursus of the Holy Spirit, has achieved an effect beyond the reach of eloquence. One can estimate the power better than the technical eloquence of such missionary preachers as Ulfilas in the 4th century, Columba in the 6th, Boniface in the 8th or Ansgar who evangelized Sweden in the 9th century.

Second, beside the great orators of the pulpit may be set those who were rulers of peoples. Such were Savonarola, who dominated Florence by the passion of his eloquence at the end of the 15th century; and the two Reformation leaders John Calvin, the master of Geneva, and John Knox in Scotland. Of Knox, James Melville recorded in his diary for 1571:

Of all the benefites I haide that yair was the coming of that maist notable profet and apostle of our nation, Mr. Jhone Knox to St. Andro. I hard him teache the prophetic of Daniel, that simmer and the wintar following. I haide my pen and my litle book, and tuk away sic things as I could comprehend. In the openinge up of his text he was moderat the space of an half houre; but when he enterit to application, he maide me sa to grew and tremble, that I could nocht haide a pen to wryt.

By 1574 Knox was physically so weak that he had to be "lifted up to the pulpit whar he behouit to lean at his first entrie . . . bot for he haide done with his sermont, he was sa active and vigorous, that he was lyk to ding that pulpit in blads and flie out of it."

Third, there are the systematic expositors of Scripture. The Greek Fathers fall into this category, as in the west does St. Augustine of Hippo. Medieval exegesis was perhaps too fanciful to come under the heading of systematic exposition. The reformer John Calvin and the 18th-century English Nonconformists Matthew Henry and Philip Doddridge were eminent expositors of the whole Bible, and outstanding among such preachers in the 19th and 20th centuries were Alexander Maclaren, Alexander Whyte and George Adam Smith.

Fourth, the type of preaching that most closely corresponds to the apostolic *kerygma* is that of the evangelists. Luther's doctrine

of justification by faith, with its corollary that "these two words, grace and peace [Gal. i, 3], do contain in them the whole sum of Christianity," was not intrinsically new, but he saw and experienced it with such power and vividness that it became for much of Christendom a republication of the apostolic gospel. In his passionate and searching proclamation of the mercies of God he was followed, after a period of Protestant scholasticism, by such preachers as John Wesley, the founder of the Methodist movement; Charles Simeon, who from King's college and Holy Trinity in Cambridge exercised an immense influence upon the Church of England and was one of the founders of the Church Missionary society; the 19th-century Baptist Charles Haddon Spurgeon, whose sermons in spite of their traditional Calvinist theology deserve study for their simple, nervous English; and his United States contemporary the traveling missionary Dwight L. Moody, who, being asked after three nights of preaching why he had not discoursed upon the wrath of God, promised that he would come to that subject when he had finished speaking of the love of God. Such men could say of themselves as the 17th-century Puritan Richard Baxter said:

I preach'd, as never sure to preach again,
And as a dying man to dying men!

It was primarily with evangelistic preaching that the churches followed up the expansion of the population westward in the United States and Canada. North America has proved fertile in the production of evangelistic preachers, among whom in the 20th century John R. Mott, "Billy" Graham and Edwin Orr have been outstanding examples. The publication in the mid-20th century of *The Interpreter's Bible* is perhaps the most notable U.S. contribution to expository preaching.

A fifth type of preaching is the very simple, colloquial and dramatic. Illustrations of this are the sermons of Peter Waldo of Lyons in the 12th century, of Bertold von Regensburg in the 13th, the famous discourse of the Reformation bishop Hugh Latimer on the playing cards and on the plow; the *Village Sermons* (1849) of Charles Kingsley; and the *Dorfpredigten* (1899-1902) of Gustav Frenssen, the German novelist who prepared his sermons as he walked through the village street and visualized the lives and hopes and fears of those who lived in the cottages he passed.

Sixth, there are the sermons more philosophical in form, such as those preached in the 17th century by the Cambridge Platonists; or in the 18th century the *Astronomical Discourses* of Thomas Chalmers and the sermons of Jonathan Edwards; and in the 19th the sermons of F. D. E. Schleiermacher, the father of modern Protestant theology, and those of James Martineau and Horace Bushnell.

Finally there is the mystical type of discourse such as the expositions of the Song of Songs by Bernard of Clairvaux in the 12th century and the sermons of Bonaventura in the 13th century, of Jean de Gerson and the Dominican Johann Tauler in the 14th, and of Peter Sterry, chaplain to Oliver Cromwell, in the 17th.

Many of the great names of the pulpit cannot be fitted easily into any of these categories, and many could be accommodated in more than one. Preaching is at once an impossible task—for what mortal man may dare to say "Thus saith the Lord God"?—yet it is a necessity laid upon many consciences: "His word was in mine heart as a burning fire shut up in my bones, and I was weary with forbearing, and I could not stay" (Jer. xx, 9). It is on the human side the most tremendous exercise of the whole personality. It may be surmised that all those whose preaching has been great in the sense of *kerygma* or proclamation might agree with the words ascribed to the notable 19th-century U.S. minister Henry Ward Beecher:

To preach the Gospel of Jesus Christ; to have Christ so melted and dissolved in you, that when you preach your own self you preach Him as Paul did; to have every part of you living and luminous with Christ, and then to make use of everything that is in you . . . all steeped in Jesus Christ, and to throw yourself with all your power upon a congregation—that has been my theory of preaching the Gospel . . . I have felt that man should consecrate every gift that he has got in him that has any relation to the persuasion of men and to the melting of men—that he should put them all on the altar, kindle them all, and let them burn for Christ's sake.

Sermon Construction.—Every preacher has his own style, and the varieties of form and manner among the acknowledged masters of pulpit eloquence are so great that it might seem foolish to suggest that there is any literary pattern to which all preaching conforms or should conform or any rules for the construction of a sermon. Yet in very general terms a common, if not universal, pattern can be found.

The middle ages knew rules and conventions of sermon construction. First, a text must be selected; this is to be, as it were, the acorn from which the whole tree of the discourse is naturally to emerge. Then a brief ante-theme should be composed, the purpose of which is to catch the attention of the audience; it may be accompanied by an invitation to prayer. The theme itself is then introduced and divided into three parts which in due course are to be developed. They are then to be confirmed by arguments from reason and from Scripture. Finally comes the *dilatatio* or peroration. Great stress was laid upon the use of *exempla* or illustrations.

This somewhat redoubtable plan does not conform to the practice of many exemplary preachers. But there is a simpler paradigm which, if it offers no binding rules, underlies the practice of many or most and carries its inherent logic. Preaching is a proclamation of the gospel from the text of Scripture; the sermon is to be an exposition of the chosen text. Its announcement is preceded or followed by a short exordium designed to indicate to the hearers that what follows is of interest and importance to them. The text, whether it refers to an event or a saying, arises always from a concrete situation. This historical situation is to be presented to the congregation with all possible vividness, so kindling their imaginations that they can visualize the scene or overhear the words of the text in their historical setting. Underlying every concrete historical situation is some principle of universal significance and application.

After his exposition of the scene the preacher therefore enlarges upon such underlying principle or principles and illustrates his argument from Scripture, from history, from literature, from imagination or any other source. In a final section the preacher brings home the significance of this exposition to the hearts and consciences of his hearers.

Such may be deemed the simple, general but flexible outline or schematism of the sermon. It may be observed that it is closely parallel to the traditional rules for the making of a meditation. First comes the exercise of the imagination, a visualizing of the scene; second follows an exercise of reflection or thought, an attempt to understand the permanent and universal principle implicit in the scene thus visualized; finally comes the exercise of the will and the decision of heart and conscience.

PRECAMBRIAN TIME. The Precambrian, as the name implies, includes all geologic time before the Cambrian Period and all rock formations older than the basal beds of the Cambrian System (*q.v.*), the earliest period of the Paleozoic Era, as indicated on the accompanying geologic time chart. (See also *Geology* and *Historical Geology*.)

In much geologic literature the early part of Precambrian time is designated the Archeozoic or Archean Era, and the later part the Proterozoic Era; and these terms are retained in *Encyclopaedia Britannica* articles dealing with areas where they remain in general use (*i.e.*, Africa, Australia). In this article Precambrian time is divided into *Early Precambrian* and *Late Precambrian*. The terminology recognizes that the total time involved is too immense

and the records in all continents are too complex for meaningful division into two formal eras. The general classification of the rock units as Early and Late Precambrian is based on stratigraphic and structural relationships. A basic requirement is regional evidence that the rocks in both groups are older than strata dated by contained fossils as Lower Cambrian. Separating the older rock units into Early and Late Precambrian must rest on regional evidence for widespread unconformity between the two, generally with more pronounced metamorphism in the lower unit. Following are the main divisions of this article:

I. Characteristics

1. Dating
2. The Precambrian World

II. The Precambrian Record

A. North America

1. Early Precambrian of the Canadian Shield
2. Late Precambrian of the Canadian Shield

III. Economic Importance

I. CHARACTERISTICS

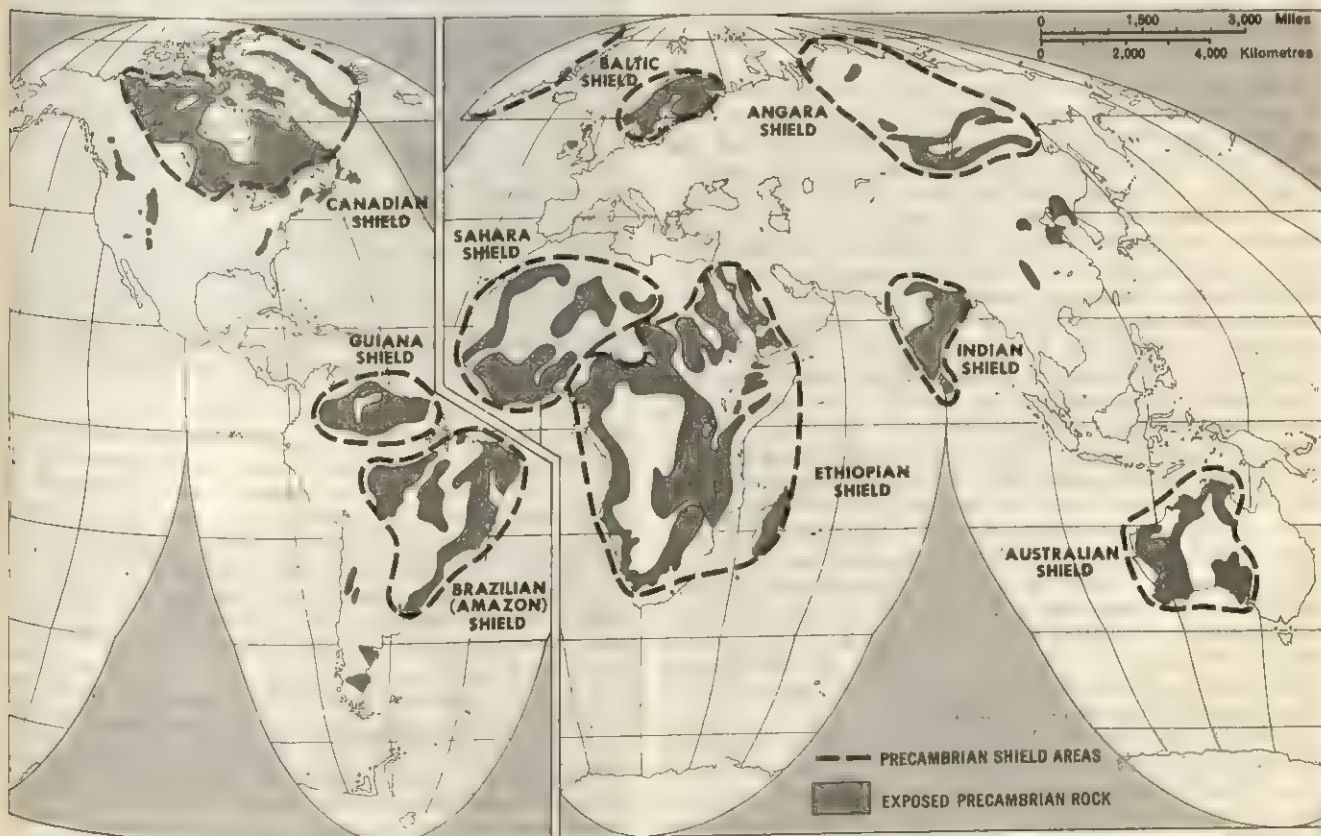

Throughout most of the world, wherever the contact of Cambrian with older rocks is exposed, there is a great unconformity or gap in the sequence of formations. In a few regions, however, there seems to be no unconformity, the Cambrian beds grading downward without interruption into strata believed to be of Precambrian age. Most of the Cambrian and younger strata contain numerous fossils that give evidence of varied and abundant life. The comparatively few fossils known in Precambrian rocks represent simple forms such as calcareous algae, microscopic fungi,

trails and burrows of worms or wormlike creatures, and possible fragments of arthropods, foraminifera, and radiolarians. The oldest fossil forms so far reported came from rocks in South Africa for which analysis by the rubidium-strontium method indicates an age more than 3,000,000,000 years. The tiny bacterium-like forms, revealed and studied by optical and electron microscopy, indicate that life began much earlier in Precambrian time than had been supposed.

Wherever erosion has removed the Paleozoic and later formations, Precambrian rocks are usually present. They are exposed over one-fifth of the land surface of the earth and, except where intruded by igneous rocks of later age, exist everywhere at depth beneath Paleozoic and later strata. They are exposed in areas of two kinds: (1) the deeply denuded parts of mountain chains where they have been uplifted by mountain building; and (2) in widely extended areas of relatively low elevation, called shields because of their gentle outward slopes resembling roughly the surface of a shield. The exposures in mountain chains are much more restricted in extent than in the shield areas.

The formations of the Precambrian are, for the most part, highly folded and intruded by masses of granite, granite gneiss, and other igneous rocks, most of which came in at depth as the Precambrian mountain-building was in progress. On the margins of the Precambrian shield areas, Cambrian and later beds in many places lie on the upturned edges of Precambrian strata. This relationship shows that, prior to the Cambrian, the Precambrian mountains were worn down to a relatively low land area over which the Cambrian seas advanced.

Although most Precambrian rocks have been subjected to the deformation and alteration that accompanies mountain-building, many of the shield areas have suffered little change through all the later eras; and original structures even of the earliest Precambrian have been remarkably well preserved. It has been found possible in many Precambrian regions, by means of detailed mapping, to determine the structural succession of formations over considerable areas. Only a relatively small part of the Precambrian has been mapped in this way; and because of the absence of diagnostic fossils, much intensive geological work will be necessary before

PRINCIPAL PRECAMBRIAN OUTCROP AREAS SHOWN IN GRAY; BROKEN LINES INDICATE SHIELD AREAS

the rocks can be correlated with certainty even within most of the separate Precambrian areas.

1. Dating.—The discovery that radioactive elements slowly disintegrate into other elements affords a way in which the approximate age of Precambrian rocks can be determined. Thus from the time a uranium-bearing mineral is formed, its uranium slowly breaks up into helium and isotopes of lead.

Since the rate of disintegration of the uranium is known, it is possible to determine the age of the mineral from the amounts of lead isotopes relative either to one another or to the uranium present. Many pegmatites and other igneous rocks of the Precambrian contain uranium-bearing minerals, the oldest of which has been determined to have an age of more than 3,500,000,000 years. The rocks in which these occur, however, are intrusive into older formations, and it has been estimated that the oldest Precambrian rocks on the earth's surface have an age of more than 4,000,000,000 years. (See also *GEOCHRONOLOGY*.)

2. The Precambrian World.—For all of Precambrian time for which there is a geological record, conditions on the surface of the earth appear to have been similar in most respects to those of later eras. Mountain-building and volcanic activity recurred as in the later periods of the earth's history; water played the same role as it does today; rocks were deeply eroded; and conglomerates, sandstones, and other sediments were deposited in the same manner as at the present time. There is evidence also that great ice sheets similar to the one now covering most of Greenland existed in Canada, India, South Africa, Australia, and elsewhere.

II. THE PRECAMBRIAN RECORD

A. NORTH AMERICA

Precambrian rocks occur in North America mainly in the Canadian Shield that occupies most of the northeastern part of the continent. They occur also in numerous scattered areas in the western or Cordilleran part and in places in the eastern belt of folded rocks that extends northward from Alabama to Newfoundland.

The Canadian Shield has the world's largest area of exposed Precambrian rocks. It includes most of northeastern Canada and the greater part of Greenland, and extends into the United States west and south of Lake Superior and in northern New York State. It has a total area of about 2,780,000 sq.mi. (7,200,000 sq.km.), of which about 800,000 sq.mi. are in Greenland, 1,905,000 in Canada, and 75,000 in the United States.

The limits of the shield are sharply defined on the east, except in eastern Greenland, by the Atlantic Ocean; and on the south and west by south- and southwest-dipping sediments of later age that crop out in alternating lowland and north- or northeast-facing scarp belts. On the north the boundary is less definite, the Precambrian disappearing first beneath scattered remnants, and finally beneath a most irregular border of Paleozoic or later sediments.

Only a small part of the shield has been mapped geologically in detail, but at the present stage of the study two major divisions of rocks are recognized—the Early Precambrian and the Late Precambrian. A major break in deposition (unconformity), used as the standard of reference for the separation of Early from Late Precambrian, was first observed in 1845 on Lake Timiskaming, on the border between Ontario and Quebec, by Sir William Logan, first director of the Geological Survey of Canada. The unconformity was later found to extend with reasonable certainty from Lake Mistassini in northern Quebec to the region south of Lake Superior in the United States, a distance of more than 900 mi. (1,450 km.). Formations beneath this unconformity in the southern part of the shield are classed as Early Precambrian, those above as Late Precambrian. In northern parts of the shield where the unconformity is not generally recognized, some rock units are assigned, on the basis of lithologic and structural similarities, to the older or younger group. Where such evidence is lacking, the bedrock is classified under the general designation Precambrian.

1. Early Precambrian of the Canadian Shield.—The Early Precambrian formations of the Canadian Shield, classified according to their lithological character and mode of origin, belong to two entirely different types. In the territory extending from the north end of Lake Huron to the Strait of Belle Isle, the Adirondack

region in New York State, Baffin Island, and Greenland, the rocks are limestone and associated sediments of the types laid down in the sea adjacent to land of low relief; whereas elsewhere in the shield limestone is almost wholly absent and the predominant formations are lava flows and clastic sediments (that is, composed of fragments of preexisting rocks), characterized by features that suggest deposition either on land or in the sea adjacent to mountains.

Information is far too incomplete for setting up a single tabular classification of the Early Precambrian rocks of the shield that would hold for its entire area; but in the Timiskaming region of northeastern Ontario and western Quebec, where an area of about 2,600 sq.mi. (6,750 sq.km.) has been mapped geologically in detail, the succession in descending order (*i.e.*, from youngest to oldest strata) is as follows:

EARLY PRECAMBRIAN ROCKS IN TIMISKAMING REGION

GREAT UNCONFORMITY

Batholithic intrusives
Granite and related rocks
Intrusive masses, dikes, and sills
Diorite, gabbro, peridotite, and related rocks
Timiskaming
Conglomerate, graywacke, and volcanic rocks

UNCONFORMITY

Pre-Timiskaming batholithic intrusives
(represented only by pebbles in Timiskaming conglomerate)
Pontiac and Hoyle groups
Graywacke, lava flows, and fine-grained volcanic ejecta (tuff)
Keewatin
Lavas, volcanic fragmental rocks (agglomerate), and tuff

In the region northwest of Lake Superior the Early Precambrian succession from youngest to oldest is the following:

EARLY PRECAMBRIAN ROCKS NORTHWEST OF LAKE SUPERIOR

Algoman batholithic intrusives
Granite and related rocks
Knife Lake, Steeprock Lake, and Seine River series
Sediments, lava flows, and pyroclastic volcanic rocks

UNCONFORMITY

Laurentian batholithic intrusives
Granite and related rocks
Keewatin
Lavas and Soudan iron formation member
Coutchiching*
Mica schist and gneiss of sedimentary origin

*Relationship of Coutchiching to Keewatin uncertain

Although the above tabulations are from localities more than 600 mi. (950 km.) apart, there is apparently considerable similarity in the succession in the two regions and, for this reason, some correlations have been attempted between them. For example, the name Keewatin (from an Indian word for "north wind"), first proposed by A. C. Lawson in 1885 for volcanic rocks occurring in the Lake of the Woods district northwest of Lake Superior, has been used by almost all geologists for similar rocks occurring in northern Ontario and eastward in western Quebec. Some geologists have also assumed that the post-Timiskaming granites of the Timiskaming region are of the same age as the Algoman (from Algoma, Ont.) granites of the region northwest of Lake Superior. According to these assumptions two separate mountain-building uplifts extended across the whole southern part of the Canadian Shield during Early Precambrian time. It is possible that detailed geological mapping in northern Ontario might prove this hypothesis, but much geological work would be required to establish it.

In the southeastern part of the Canadian Shield, where the

Grenville (Grenville, Ont.) sediments, believed to be of marine origin, occur, the most complete succession of formations is in southeastern Ontario. A tabular statement of the sequence of formations in this region is as follows:

EARLY PRECAMBRIAN ROCKS IN SOUTHEASTERN ONTARIO

Batholithic intrusives

Granite, granite gneiss, syenite, and related rocks

Diorite, gabbro, and related rocks

Hastings series

Limestone, dolomite, graywacke, mica schist, conglomerate

UNCONFORMITY

Batholithic intrusives

(represented only by pebbles in Hastings conglomerate)

Grenville series

Crystalline limestone, dolomite, quartzite, garnet gneiss, mica schist, lava flows, pyroclastic volcanic rocks

Except for the presence of the Hastings (Hastings County, Ont.) series and the Grenville volcanic rocks restricted mainly to southeastern Ontario, the above succession is similar to that throughout most of the Grenville subprovince that extends from the north end of Lake Huron and the Adirondack region northeast to the Strait of Belle Isle. However, at Mt. Wright and Wabush Lake about 220 mi. (350 km.) north of the lower St. Lawrence, recrystallized iron-bearing sediments are believed to be a southern part of the Labrador-Quebec Late Precambrian sedimentary belt.

2. Late Precambrian of the Canadian Shield.—Late Precambrian rocks occur extensively in the southern part of the Canadian Shield south and northwest of Lake Superior and in the territory extending northeast from the north shore of Lake Huron to Lake Timiskaming. In the region south of Lake Superior in 1935 they were called Algonkian type and classified by C. K. Leith, R. J. Lund, and A. Leith in descending order as follows:

LATE PRECAMBRIAN ROCKS SOUTH OF LAKE SUPERIOR

KEWEENAWAN—Acidic intrusives
Basic intrusives
Sandstone, shale, conglomerate, lava flows

UNCONFORMITY

UPPER HURONIAN—Sediments, iron formation, volcanic rocks

UNCONFORMITY

MIDDLE HURONIAN—Basic intrusives, iron formation, sediments

UNCONFORMITY

LOWER HURONIAN—Dolomite and quartzite

UNCONFORMITY

In the region northwest of Lake Superior, F. F. Grout, J. W. Gruner, G. M. Schwartz, and G. A. Thiel in 1951 classified the younger group of rocks as follows:

LATE PRECAMBRIAN ROCKS NORTHWEST OF LAKE SUPERIOR

KEWEENAWAN—Upper—Sandstone, other sediments
Middle—Acid, basic intrusives, lavas
Lower—Conglomerate, sandstone

UNCONFORMITY

ANIMIKIE—Slate, iron formation, and quartzite

UNCONFORMITY

In the Lake Huron-Lake Timiskaming region in northern Ontario the Late Precambrian rocks are classified as follows:

LATE PRECAMBRIAN ROCKS IN NORTHERN ONTARIO

Acid and basic intrusive rocks

Whitewater series

UNCONFORMITY

Cobalt series

UNCONFORMITY

Bruce series

UNCONFORMITY

Of the above, the Bruce series is probably the eastward continuation of the Lower Huronian of the region south of Lake Superior. The Cobalt series, although believed to be, in part, of glacial origin, is usually classified as Middle Huronian. The correlation of the Whitewater series is in doubt. It was formerly thought to be Keweenawan or possibly Animikie, but in 1956 J. E. Thomson suggested that this series might be considerably older.

In the vast northern part of the shield, extending from the Strait of Belle Isle to Great Bear Lake and the Arctic Ocean, the Late Precambrian rocks belong to three main classes: (1) in the northern part of the shield west of Hudson Bay, extensive separate areas of flat-lying conglomerate, sandstone, and lava flows known from place names as the Coppermine River, Et-then, Dubawnt, and Athabasca groups; (2) in the eastern part of the shield, areas or belts of partly folded and partly gently dipping iron formation, dolomite, and clastic sediments of the Belcher Islands, Richmond Gulf, Labrador-Quebec, or similar groups; and (3) in the northwestern part of the shield unconformably beneath the Coppermine River and Et-then rocks, zones of folded dolomite, limestone, quartzite, and graywacke called the Great Slave, Snare, and Nonacho groups. The rocks of class 1 are similar to the Keweenawan of the Lake Superior region; those of class 2 to the Animikie northwest of Lake Superior; and those of class 3 to the Huronian south of Lake Superior.

3. Other North American.—In the western Cordilleran part of North America, the best known section of Precambrian rocks is that exposed in the Grand Canyon of the Colorado River in Arizona. The most extensive occurrence, however, is that of the Late Precambrian Beltian (Little Belt Mountains, Mont.) formations. These occupy an area 300 mi. (475 km.) wide in northern Idaho, Montana, and Washington, and extend discontinuously northwest with a maximum width of about 100 mi. (160 km.) through British Columbia to the Yukon in Canada.

In addition to occurrences in the Grand Canyon area, Precambrian rocks are widely scattered in southern, southwestern, and western parts of Arizona. In the Grand Canyon gorge the oldest rocks, known as the Vishnu schist, are classed as Early Precambrian. They consist of igneous gneisses and altered sedimentary rocks. They are cut by dikes of granite and pegmatite. A younger group of Precambrian rocks 12,000 ft. (3,600 m.) thick, the Grand Canyon series, composed mainly of sediments, rests unconformably on the Vishnu schist. In other parts of Arizona the older Precambrian rocks are known as the Yavapai or Pinal schist, and the younger as the Apache group.

The rocks of the Beltian System include argillite, impure limestone, quartzite, and other sediments. They are estimated to have a thickness up to 35,000 ft. (10,700 m.) in the United States. In Canada, according to H. M. A. Rice, they have a total thickness of 67,000 ft. (20,400 m.) and occur in two series separated by an important unconformity.

In the belt of folded rocks that lies parallel with the east coast of North America, there are Precambrian rocks in eastern Newfoundland, in southeastern Nova Scotia, along the northwest shore of the Bay of Fundy in New Brunswick, and in zones within or adjacent to the eastern part of the Appalachian Mountains from the Canadian border to Georgia. In southeastern Pennsylvania and adjacent parts of New York, New Jersey, and Maryland, the

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	Began (Millions of Years Ago)
CENOZOIC ERA			
Quaternary	Recent (last 11,000 years)		
	Pleistocene	Early man	2+
	Pliocene	Large carnivores	10
	Miocene	Whales, apes, grazing forms	27
Tertiary	Oligocene	Large browsing mammals	38
	Eocene	Rise of flowering plants	55
	Paleocene	First placental mammals	65-70
MESOZOIC ERA			
Cretaceous		Extinction of dinosaurs	130
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	180
Triassic		Appearance of dinosaurs	225
PALEOZOIC ERA			
Permian		Reptiles developed, conifers abundant	260
Carboniferous	Upper (Pennsylvanian)	First reptiles, coal forests	300
	Lower (Mississippian)	Sharks abundant	340
Devonian		Amphibians appeared, fishes abundant	405
Silurian		Earliest land plants and animals	435
Ordovician		First primitive fishes	480
Cambrian		Marine invertebrates	550-570
PRECAMBRIAN TIME			
		Few fossils	more than 3,490

Precambrian includes sedimentary and igneous gneisses overlain unconformably by crystalline limestone, dolomite, quartzite, sedimentary gneisses, and schists. The older group of rocks is known as the Baltimore gneiss; the younger as the Glenasmole series. Farther south the schists and gneisses of the Blue Ridge and the (Piedmont) plateau belts have been classed as Precambrian by most geologists who have examined them.

B. SOUTH AMERICA

Precambrian formations crop out in South America mainly in two regions: (1) in elongated zones here and there in the western Cordilleran belt of mountains extending from Venezuela to Chile; and (2) in broad masses or scattered areas in the eastern part of the continent, but most extensively in Brazil, southeastern Venezuela, French Guiana, Surinam, and Guyana. The territory in northeastern South America underlain by Precambrian rocks lying south of the Amazon basin is known as the Brazilian or Amazon Shield; that north of the Amazon basin as the Guiana Shield. The zones of the Cordilleran region consist mainly of granite, schists, and gneisses, which have been classed as Early Precambrian largely because of their highly altered condition. The succession of formations in central and southeastern Minas Gerais State, Brazil, is believed to be typical of the Amazon Shield. The oldest rocks of this region include gneisses and schists, presumably transformed sediments, overlain successively by two groups of Late Precambrian sediments: the Minas series, composed mainly of quartzite, slate, dolomite, conglomerate, and iron formation called itabirite; and the Itacolumi series, consisting chiefly of quartzite. All of these have been affected by mountain-building, as shown by their highly folded condition and intrusion by granite.

The oldest rocks of the Guiana Shield are crystalline schists, limestone, gneisses, and granite of Early Precambrian age. These are overlain in unconformable succession by two groups of Late Precambrian rocks: (1) the Balling series, composed of lava flows with interbedded iron formation and other sediments; and (2) the Orapu, a sedimentary series consisting of conglomerate, quartzite, and slate. Mountain-building and granitic intrusion followed the deposition of both the Balling and Orapu formations.

Important mineral deposits occur in both the Amazon and Guiana shields. These include hematite iron ore, manganese, gold, mica, and diamonds in Brazil; gold in Guyana; and hematite-magnetite iron ore in Venezuela.

C. EUROPE

Small areas or zones of Precambrian rocks occur widely scattered in Europe wherever deeply eroded folded rocks of mountains or former mountains are present, but by far the largest area underlain by Precambrian formations is that known as the Baltic Shield

(Baltica or Fennoscandia), which occupies a large part of Norway, and most of Sweden, Finland, and northwestern U.S.S.R. west of the White Sea. There are also considerable areas of Precambrian in the Highlands of Scotland and northeastern Ireland that may be parts of a western extension of the Baltic mass.

The most important mineral deposits in the Precambrian of Europe are in the Baltic Shield. These include magnetite iron ore at Kiruna in Sweden and apatite (phosphate rock) in the Kola Peninsula of the U.S.S.R.

1. Fennoscandia (Baltic Shield).—The Precambrian area of Fennoscandia or the Baltic Shield extends from the Arctic Ocean to the island of Bornholm in the Baltic Sea and from the eastern extremity of the Kola Peninsula in the U.S.S.R. to the westernmost tip of Norway. In the 1930s J. J. Sederholm classified the Precambrian rocks of this region into four divisions: (1) Sivonian; (2) Bothnian; (3) Jatulian-Kalevian; and (4) Jotnian, each of which he believed was separated from the underlying and overlying divisions by great unconformities. He also believed that the intervals of erosion represented by these unconformities in every case were preceded by mountain-building and intrusion of granitic rocks which were laid bare by erosion before the succeeding formations were deposited. Finnish and Swedish geologists have concluded from later work, however, that mountain-building did not intervene between the Sivonian and Bothnian rocks, and that these belong to a single group. This Sivonian-Bothnian succession of formations includes abundant altered sandy sediments, conglomerate, limestone, and interbedded volcanic rocks. They are intruded by basic igneous rocks and post-Bothnian granite. The Jatulian-Kalevian group is composed of conglomerate, ripple-marked quartzite, dolomite, and greenstones that have been transformed by folding and intrusion of granite. During the Late Precambrian the peculiar Rapakivi granite was intruded, after which the Jotnian sandstone was deposited. Since the earlier work of Sederholm, considerable progress has been made in the study of the granitic rocks of Fennoscandia; and some Finnish geologists, notably P. Eskola, have concluded that these igneous intrusions are related to two mountain-building uplifts: (1) the Svecofennidic or post-Sivonian; and (2) the Karelidic or post-Kalevian. According to Eskola, the Svecofennidic mountain chain extended east-west through central Sweden and southwest Finland; the Karelidic mountain-folding trended northwest from Lake Ladoga through eastern Finland and Lapland. In the folded Caledonian Mountains of Norway, thick sandy sediments, known as the Sparagmite or Eocambrian formation, occur extensively at the top of the Precambrian succession.

2. Scotland.—The Precambrian of Scotland lies north of the great fault that marks the southern border of its Highlands. In this region there are four main rock groups of Precambrian or possible Precambrian age. These are: (1) The Lewisian (from Lewis and Harris Island in the Outer Hebrides) complex, consisting of sediments that have been transformed into gneisses and schists, and intruded by granite, igneous gneisses, pegmatite, and ultrabasic rocks. It occurs in the northwest Highlands and in the Hebrides Islands. (2) The Moine series, composed of metamorphosed sediments, ultrabasic or basic intrusive rocks, and banded gneisses formed by the intrusion of granite into schist. (3) The Dalradian (from the region of Dalradian, Scot.) series, a metamorphic group of rocks mainly of sedimentary origin. It occurs in the southeast Highlands north of the Highland boundary fault. (4) Unaltered conglomerate, sandstone, grit, and shale—the gently folded Torridonian (from Loch Torridon, Scot.) sediments. They rest unconformably on Lewisian gneiss in the northwest Highlands in the Hebrides, and other adjacent islands, and are overlain with structural unconformity by Cambrian sediments.

The Lewisian presumably belongs to the Early, and the Torridonian to the Late Precambrian. The Moine sediments have been variously classified as Lewisian, post-Lewisian but pre-Torridonian, Torridonian, or early Paleozoic transformed by Caledonian mountain-building. According to James Phemister, the post-Lewisian pre-Torridonian age is probably the most generally accepted hypothesis. The Dalradian rock group is of uncertain age. Some geologists think it Precambrian but others maintain that it belongs wholly or in part to the Cambrian.

D. ASIA

Rocks that are positively known to be Precambrian, or are probably Precambrian, are widespread in Asia wherever eroded mountains occur. The most extensive areas, however, are in eastern Siberia, northeastern China, Korea, India, and Arabia.

1. **Siberia.**—The Precambrian Angara Shield of Siberia occupies two extensive areas in the headwater parts of the Yenisei and Lena river basins. The northeasterly of these is called the Anabar Massif and that to the southeast the Aldan Plateau. The rocks in the central parts of these ancient land masses include crystalline limestone, quartzites and other metamorphosed sediments, schists, gneisses, and intrusions of granite. In their border zones, notably in the Lake Baikal region, the Early Precambrian complex is overlain unconformably by a folded succession of two Late Precambrian structurally unconformable, metamorphic series. The lower of these consists of schists, conglomerate, and quartzites; the upper of phyllites, sandstone, and interbedded lava flows. In parts of the region Cambrian strata rest on the Early Precambrian complex, and Late Precambrian strata are absent. Geologists of the U.S.S.R., noting the wide zone of unfolded Paleozoic rocks that commonly encircle the Precambrian shield areas, designate the combined shield and surrounding undeformed formations as platforms.

2. **China.**—In China Precambrian rocks occur widely from Mongolia southeast, east, and northeast to the Siberian border. They belong to three unconformably separate groups: (1) the Tai-Shan (Early Precambrian) complex of gneisses, schists, and altered sediments, intruded by granite and basic igneous rocks; (2) the Wu-T'ai System composed of dolomite, conglomerate and other sediments metamorphosed to schists, interbedded greenstones—probably altered volcanic rocks—and gneisses intruded by granite; and (3) the Sinian System consisting of limestone, quartzite, shale, and other sediments. The Wu-T'ai is compared by some authors with the Huronian of North America. The Sinian is similar in many respects to the Beltian sediments of western United States and Canada. In Manchuria and Korea the names Lia-ho and Keirin have been given by Shintaro Nakamura to rocks believed to be the equivalent of the Wu-T'ai and Tai-Shan systems. Geologists conclude that Precambrian granitic rocks of three ages occur in north China and Korea.

3. **India.**—The bedrock surface of peninsular India and the adjacent island of Ceylon is composed mainly of highly folded, crystalline schists and gneisses intruded by granite and granite-gneiss, and a widespread group of igneous rocks containing the mineral hypersthene and known as the Charnockite series. This complex was called Vedic and correlated with the Early Precambrian by Sir Thomas H. Holland. It includes an abundance of crystalline limestone, and other highly altered sediments, which, as noted by F. D. Adams in Ceylon, resemble the Grenville series in the southeastern part of the Canadian Shield.

In parts of the peninsula the sediments and schists of sedimentary origin within the complex are known as the Dharwar System. These Early Precambrian rocks are overlain unconformably by great thicknesses of little-disturbed rocks called Purana. They contain no fossils and are believed to be of Late Precambrian age. The Purana sediments have been variously named in different parts of the peninsula. In central India they are divided into two series separated by an unconformity, the Gwalier and Vindhyan. The gold-bearing veins of the Kolar goldfields in Mysore intersect schists of the Dharwar System. Deposits of white mica (muscovite) occur in pegmatite dikes cutting the Dharwar or similar rocks in several provinces of India. The graphite of Ceylon occurs in veins cutting the older gneisses.

E. AFRICA

Precambrian rocks occur in many places in Africa but are most widespread in an irregular zone extending longitudinally from Arabia and Egypt to Cape Province in South Africa, and transversely from the Gulf of Aden almost to the western extremity of the continent. They also underlie most of the island of Madagascar and occur discontinuously in a narrow belt adjoining the west coast from the Gulf of Guinea southward. In most of these regions they are not in contact with Cambrian formations but are

overlain with great unconformity by Devonian, Permo-Carboniferous, or later strata. Their classification as Precambrian is, therefore, based largely on their metamorphic condition and lithological character.

In most of the Precambrian areas of Africa, a highly deformed basal group of schists and gneisses, usually called the Basement, is overlain with great unconformity by one or more less altered rock series. A multitude of local names have been given to these various rock groups but only those occupying extended areas can be mentioned. In the Sahara region of North Africa, two major rock divisions have been observed; the lower is known as Suggarien and the upper, Pharusien. To the southwest, in former French West Africa and Ghana, the names Dahomeyan, Birrimian, and Tarkwaian have been used over a large area.

In Kenya and Tanganyika, which are predominantly underlain by Precambrian rocks, the Precambrian formations are classified into three main groups: the Basement, Nyanzian, and Kavirondian systems. Extensive areas of gneiss and granite intervening in age between the Basement and Nyanzian systems have been mapped as the Granitoid Shield by G. M. Stockley.

The major Precambrian divisional names in southeast Africa are included in the following table:

Precambrian Divisional Names, Southeast Africa

Waterberg System Conglomerate, quartzite, shale, volcanic rocks

Transvaal System

Pretoria series Conglomerate, quartzite, shale, and lavas

Dolomite series Dolomite, chert, and quartzite

Black reef series Conglomerate, quartzite, and shale

Ventersdorp System .. Conglomerate, quartzite, chert, shale, and volcanic rocks

Witwatersrand System

Upper division Conglomerate, grit, and quartzite

Lower division Conglomerate, arkose, quartzite, slate, lavas

The Witwatersrand rocks are of special interest because they contain the world's largest known deposits of gold. They have a total thickness of more than 24,000 ft. (7,300 m.). The gold occurs in conglomerate beds known as bankets or reefs. In South West Africa and western South Africa, a succession of conglomerates, quartzites, dolomite, and limestone called the Nama System, because of lithological similarity, has been correlated tentatively with the Transvaal rock group. One of the outstanding features of the South African Precambrian is the widely extended assemblage of volcanic and intrusive igneous rocks known as the Bushveld complex that occurs in central Transvaal. This igneous activity occurred mainly between late Pretoria and Waterberg deposition. Considerable amounts of tin and chrome ore are found in the intrusive phases of the Bushveld complex.

F. AUSTRALIA AND NEW ZEALAND

The Precambrian formations of Australia and New Zealand occur in either (1) relatively small scattered areas or zones in the cores of mountains or highlands in New South Wales, South Australia, northern Queensland, western Tasmania, and southwestern New Zealand; or (2) in the widely extended shield area of western and central Australia. In most of these regions an older group of schists, gneisses or volcanic rocks, and intrusive granite is overlain unconformably by less deformed sediments or lavas. At Broken Hill in New South Wales highly altered sandy, argillaceous, and calcareous sediments of the Early Precambrian Willyama series are overlain unconformably by the Late Precambrian Torrowwangee series composed of limestone, shale, and boulder beds.

In New South Wales the older sediments of the Hutchison series and granite gneisses are overlain unconformably by folded limestone, quartzite, and slate of the Adelaide series. In the Mount Isa region of western Queensland, the Precambrian is represented by four rock groups separated by unconformities. The two older of these, the Kalkadoon-Argylla and Soldier's Cap series, are assigned to the Early Precambrian; and the two younger, the Mount Isa and Mount Quamby series, to the Late Precambrian. The Mount Quamby rocks, in contrast with the underlying formations,

are only gently dipping. In the shield area of western and central Australia, the Precambrian rocks are classified into two major divisions: (1) a basal group of mainly volcanic rocks but including some interbedded sediments, the Yilgarn-Kalgoorlie system; and (2) the younger Nullagine series composed of gently folded unmetamorphosed conglomerate and other sediments, lavas, and fragmental volcanic rocks. Masses of granite intrude the older system and are overlain unconformably by the Nullagine series.

A considerable part of the gold of Australia has been obtained from lodes and veins occurring in the Precambrian Shield of west and middle Australia. The silver-lead-zinc ores of Broken Hill in New South Wales are in intensely altered Precambrian rocks; iron ore is mined from the Early Precambrian rocks of the Middleback Range in South Australia.

G. ANTARCTICA

The continent of Antarctica, with its margin generally concentric to the South Pole, has an area almost half that of Africa. An ice cap with average thickness of many thousands of feet covers the greater part of the bedrock surface. Geologically, the continent is divided in a general way into West Antarctica, which lies south of South America, and East Antarctica, which lies south of Australia and Africa. For general description and geology of both West and East Antarctica see ANTARCTICA.

East Antarctica is regarded as a shield area. The known bedrock consists of an elevated Basement complex of schists, gneisses, and granitoid intrusives, overlain by little-deformed clastic sedimentary rocks of Paleozoic and Mesozoic age with included basic sills and dikes. Steep faults bound and offset some mountain blocks, but no folds of consequence are exposed. Surveys along lines crisscrossing the continent have given exact altitudes on the ice at numerous stations and, by use of seismic equipment, have determined thicknesses of the ice cap. Resulting profiles on the bedrock indicate a surface of low relief similar to that of eastern Canada. This indication of the general surface form, coupled with evidence that a complex of metamorphic rocks is widespread beneath little-deformed Paleozoic strata, leads to a logical supposition that much or all of East Antarctica is a Precambrian shield.

Much of the reliable geologic evidence on Antarctica has come from intensive exploration by field parties from several nations, starting in the International Geophysical Year, 1957. See INTERNATIONAL GEOPHYSICAL YEAR.

III. ECONOMIC IMPORTANCE

Because most valuable mineral deposits are found in association with igneous rocks of deeply denuded mountainous or formerly mountainous regions, the Precambrian parts of the earth's surface are of special economic importance. Most of the world's largest gold mines, including those of the Transvaal and Rhodesia (Africa), South Dakota (U.S.), northern Ontario and Quebec (Canada), Brazil, and western Australia, are in Precambrian rocks.

The important iron deposits of the Lake Superior region in the United States, the iron deposits of Labrador-Ungava, the iron ores of Brazil and northern Sweden, the great nickel-copper ore masses of Sudbury, Ont., the silver-bearing cobalt-nickel veins of Cobalt, Ont., the occurrences of uranium in South Africa and Canada, and many important copper deposits belong to the Precambrian. It also includes a great variety of useful nonmetallic minerals. Among these are garnet, talc, mica, graphite, feldspar, and magnetite.

PRECESSION OF THE EQUINOXES, in astronomy, an

effect connected mainly with a gradual change of the direction of the earth's axis of rotation. There is a general resemblance between the motion of the earth and that of a spinning top. It is well known that when a spinning top is slightly disturbed its axis gyrates, or precesses, round the vertical so that it traces out a cone; the earth's axis similarly describes a cone at the rate of one revolution in about 26,000 years. In applying this analogy the ecliptic (i.e., the plane of the orbit of the earth round the sun) must be taken to correspond to the horizontal; the axis about which the earth spins is inclined at $23\frac{1}{2}^\circ$ to the "vertical," and keeping this inclination, it turns slowly round the "vertical." It must be emphasized, however, that this correspondence between the earth and a top is superficial, the cause of the precessional motion being governed by different principles.

In this way the North Pole of the celestial sphere describes among the constellations a circle of $23\frac{1}{2}^\circ$ radius, making a revolution in 26,000 years. At present it is near the star α Ursae Minoris, which is therefore called the polestar; but it has traveled a considerable distance within historic times. About 3000 B.C. the star α Draconis would have served as polestar; in 13000 B.C. also in A.D. 13000 Vega would be near enough to the pole to mark roughly its position. By this displacement the part of the sky visible from a particular terrestrial station gradually changes; certain constellations cease to rise above the horizon and others appear for the first time. In the time of the early Chaldean astronomers it was not necessary to travel so far south to see the Southern Cross as it is now.

Cause of Precession.—This was first explained by Isaac Newton. It is due to the attraction of the sun and moon on the equatorial protuberance of the earth, the moon being responsible for

about two-thirds and the sun for one-third of the motion—the same proportion as the lunar and solar tides. Treating the equatorial bulge as an extra ring of matter surrounding a spherical earth, the attraction of the sun and moon on this ring forms a couple that tends to turn the ring into the plane of the ecliptic, since both disturbing agents are in or near the ecliptic. If the earth were not spinning this would turn the earth over until the equator coincided with the ecliptic, but the spinning earth behaves like a gyrost, so that its axis moves at right angles to the plane of the couple—just as the couple, which would upset a top at rest, gives the axis of the spinning top a conical motion.

The moon's orbit is inclined at about 5° to the ecliptic, but it does not remain still; its nodes travel round the ecliptic in 18.6 years. Averaged over a long period of time the deviations of the moon from the ecliptic cancel out; however, at any moment the precession caused by the moon may be greater or less than the average, according to the position at the time of the lunar orbit. In fact the path of the pole among the stars is a slightly sinuous curve. Astronomers distinguish the average secular motion as precession and the periodic fluctuations or sinuosities as nutation.

As the pole (corresponding to the equator) moves round the pole of the ecliptic, so the equinox or intersection of the equator and ecliptic moves round the ecliptic once in 26,000 years. Both right ascensions and longitudes are reckoned from the equinox as zero point; stellar longitudes on this account increase steadily by nearly a minute of arc every year; the effect on the right ascensions is more complicated, but these also continually increase. The vernal equinox is commonly called the first point of Aries, but it has already moved away from that constellation and is now in Pisces. It should be understood that the precession of the equinoxes has no effect on the seasons, and, for example, has no connection with the gradual departure of the spring equinox from March 21 which occurred in the old Julian calendar.

Planetary Precession.—Besides the foregoing lunisolar precession, a phenomenon of much smaller magnitude, known as planetary precession, is recognized. It is due to perturbations by the planets which cause slow changes in the plane of the earth's orbit. Planetary precession changes the position of the ecliptic, whereas lunisolar precession changes the position of the equator; either change affects the equinox, which is the intersection of the two planes. Corrections for precession and nutation are of great importance in most branches of positional astronomy.

PRECIPITATION, in meteorology, denotes all forms of water falling upon the earth's surface. It includes rain (see RAINFALL) and snow (*q.v.*) and their various modifications such as drizzle, freezing rain, sleet, snow pellets and hail. Precipitation is considered to be one of the most important of all meteorological elements since it is the only important source of fresh water.

The essential difference between a precipitation particle and a cloud particle is one of size. An average raindrop has a mass equivalent to several million cloud droplets. Because of their large size, precipitation particles have significant falling speeds and are able to survive the fall from the cloud to the ground. (See CLOUD.)

Precipitation Formation.—The transition from a cloud containing only cloud droplets to one containing a mixture of cloud droplets and precipitation particles involves two basically different steps: formation of incipient precipitation elements directly from the vapour state; and subsequent growth of these elements through aggregation and collision with cloud droplets. The initial precipitation elements may be either ice crystals or chemical solution droplets.

Development of precipitation through the growth of ice crystals depends upon the fact that cloud droplets usually do not freeze at temperatures warmer than about -40°F (-40°C). (The reduction of cloud droplets to temperatures below the normal freezing point is termed supercooling.) Within supercooled clouds, ice crystals may form through sublimation of water vapour upon certain atmospheric dust particles known as sublimation nuclei. In natural clouds, ice crystals form at temperatures colder than about $+5^\circ\text{F}$ (about -15°C). The exact temperature of ice-crystal

formation depends largely upon the physical-chemical nature of the sublimation nucleus. (See also DUST.)

Once they are formed within a supercooled cloud, ice crystals will continue to grow as long as their temperature is colder than freezing. The rates of growth depend primarily upon the temperature and degree of vapour saturation of the environmental air. The crystals grow at the expense of the water droplets. As the crystals grow, the droplets evaporate by virtue of the fact that the saturation vapour pressure over an ice crystal is less than over a supercooled water surface at the same temperature. In favourable conditions, *e.g.*, in a large, rapidly growing cumulus cloud, an ice crystal will grow to a size of about 0.005 in. in three to five minutes after formation. At this size, the rate of growth through sublimation slows down and further growth is largely through aggregation and collision with cloud droplets.

Small solution drops are also important as incipient precipitation particles. The atmosphere contains many small particles of soluble chemical substances. The two most common are sodium chloride, swept up from the oceans by spray and bubbles, and sulfate-bearing compounds formed through gaseous reactions in the atmosphere. Such particles, known as giant condensation nuclei, collect water because of their hygroscopic nature and, at relative humidities above about 80%, exist as solution droplets. In tropical maritime air masses the number of giant condensation nuclei frequently is very large. Clouds forming in such air may develop a number of large solution droplets long before the tops of the clouds reach temperatures favourable for the formation of ice crystals.

Regardless of whether the initial precipitation particle is an ice crystal or a droplet formed on a giant condensation nucleus, the bulk of the growth of the precipitation particle is through the mechanisms of collision and coalescence. Because of their larger size, the incipient precipitation elements fall faster than cloud droplets. As a result they collide with the droplets lying in their fall path. The rate of growth of a precipitation particle through collision and coalescence is governed by the relative sizes of the particle and the cloud droplets, the size and number of cloud droplets, the fraction of the droplets in the fall path which are actually hit by the precipitation particle and the fraction of these droplets which actually coalesce with the particle after collision. Under ordinary cloud conditions it takes between 10 and 20 minutes for an incipient precipitation element to grow into a large raindrop or a large snowflake.

The efficiencies of the natural precipitation processes are known to be rather low. Although vast amounts of vapour are condensed into cloud droplets to form clouds, most of this water re-evaporates without becoming involved in the precipitation processes. Precipitation particles also suffer considerable loss from evaporation in falling from the cloud bases to the ground. Studies carried out on thunderstorms in the humid eastern part of the United States show that only about 20% of the condensed water reaches the ground as rain. In the arid regions, the bases of clouds may be so far above the ground that most of the rain is evaporated between the clouds and the ground. (See CLIMATE AND CLIMATOLOGY.)

Measurement of Precipitation.—Rain gauges and snow gauges are used for measuring precipitation. The amount of precipitation is expressed in terms of the total equivalent amount of liquid water. Thus snow, caught in a gauge, is melted before measurement. In regions where snow forms an important fraction of the precipitation, it is customary to measure the amount of snow by means of a snow survey. (See SNOW.) In snow surveys it is necessary to determine the density as well as the depth of the snow in order to determine the water content.

The data from rain gauges and snow surveys are subject to large sampling errors, particularly during periods of shower and thunderstorm activity. The spacing between gauges usually is several times the size of the shower rain area. Over a period of several weeks or months errors due to rain-gauge spacing tend to be averaged out.

Precipitation measurements, when collected from many places, form the basis for estimating the amount of rain falling in a region. Such data are available for regions all over the globe. Because

of the problems of sampling rainfall and because of variations in rainfall from one year to the next, climatologists desire at least 40 years of record for computing average annual precipitation amounts.

The development of centimetre wave-length radar during World War II gave the first means of accurately identifying and locating precipitation areas. (See RADAR METEOROLOGY.) When combined with a few scattered rain gauges, radar enables meteorologists and hydrologists to determine the amount of precipitation falling on a given area more accurately than with the rain gauges alone.

Artificial Control of Precipitation.—Throughout recorded history, there have been attempts to control precipitation. Early societies employed various forms of magic in their efforts to increase rainfall. During the latter part of the 19th century, experiments using cannon shots, explosions and large fires were carried out for the same purpose. During World War I it was not infrequently observed that rain occurred during or immediately following major battles, and it was believed by many that the sounds of the cannons were responsible for causing the clouds to release the rain. Subsequent findings disproved this idea.

The first series of systematic experiments designed to discover the physics of precipitation and thereby find a means of producing precipitation were carried out by Vincent J. Schaefer in 1946. These experiments, ultimately involving seeding clouds with silver iodide smokes, were successful in causing light snow to fall from supercooled stratified clouds.

Experiments to increase precipitation rest upon the hypothesis that natural precipitation is limited by a shortage of natural precipitation nuclei. Silver iodide smokes, produced by burning a silver iodide-acetone solution, will supply sublimation nuclei effective at temperatures colder than about 23° F (about -5° C). A different approach to the problem of increasing rain involves the release of giant condensation nuclei, or small waterdrops, into suitable clouds in order to initiate rain through the collision-coalescence mechanisms.

Whether or not the amount of precipitation at the ground can be increased through any of these techniques depends largely upon large-scale meteorological factors governing the formation, growth, duration and dissipation of the clouds.

Because of the fact that natural rain is highly variable in time and space, very carefully designed experiments are necessary in order to determine the efficacy of any given rain-making technique. When rain falls from a seeded cloud, one naturally asks whether or not it would have fallen had the cloud not been seeded. When rain fails to fall, one asks whether seeding prevented it. Because of this uncertainty it is impossible to estimate the effect of cloud seeding from a few isolated experiments or from experiments which do not include a group of randomly selected, nonseeded control cases, as statistical methods would require.

From the extensive experiments carried out between 1946 and 1956, it was learned that it is possible to modify some clouds and in some very favourable conditions to cause more precipitation to fall than would have fallen through natural processes. The magnitudes of these increases are not known, although they are usually thought to be less than 10%.

PRECIPITATION, ELECTROSTATIC, is a process for removing small particles, smoke and fumes from air and gases. The precipitation of smoke by electricity was described in 1824 by M. Hohlfield, a teacher of mathematics in Leipzig, Ger., but only after it was independently rediscovered and critically studied by Sir Oliver Joseph Lodge about 1884 did it attract general attention and lead to attempts at industrial applications. At the time, however, these proved unsuccessful because of the lack of modern equipment. It was not until 1906, following experiments by F. G. Cottrell at the University of California, Berkeley, that the process was commercially successful.

The first installation was at the Selby Smelting works, near San Francisco, Calif., where it was used for the removal of sulfuric

acid mist from about 5,000 cu.ft. (142 cu.m.) of gases per minute. Later the process was successfully extended to the removal of cement dust at nearly red heat from 1,000,000 cu.ft. (28,317 cu.m.) of gas per minute at the Riverside Portland Cement company, a mill in the heart of the California orange groves threatened with legal closure as a nuisance because of the dust emitted.

The method removed 98% of the dust, the daily catch being about 100 tons. Dust removal efficiency in modern industrial plants rarely exceeds 99%. Although first applied purely to mitigate nuisances, the demand for the process is primarily based on the greater profit to be derived from the cleaned gases or the material removed. At one time the Riverside plant was making even more profit from potash incidentally recovered in its dust than from its cement.

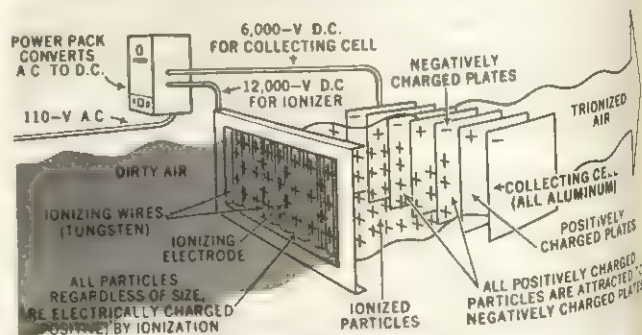

The Process.—Technically the process consists in securing a uniform, copious but nondisruptive corona discharge of electricity from small electrode surfaces of one polarity into a stream of cloudy gas. The fine solid or liquid particles composing the dust, fumes or smoke are attracted to, and deposited on, large electrode surfaces of opposite polarity, the particles having become charged from the depletion or gain of electrons on their surfaces; i.e., ionization.

Several variations on the process have been incorporated into the original Cottrell design, which, in principle, consists of a single-stage discharge and collection unit. This design as well as those having two stages—one for discharge and a second for collection—may have automatic washing systems which permit continuous operation.

Another type of precipitator is based upon the collection of ionized particles on electrostatically charged dry filters, such as cellulose mats, which have a large surface area and great dirt-holding capacity. Still another design relies solely on the ability of dust particles to be trapped on electrostatically charged filters without a prior ionization or discharge step. One advantage to these designs is that mechanical filtering is available in case of failure of the electrical system; however, filters offer resistance to air flow, especially under dirty or humid conditions, and must be replaced periodically.

In the Cottrell type of precipitator a single vertical tube or bank of tubes is commonly used. Each tube has a wire electrode suspended axially and insulated so that a voltage may be maintained between the wire and the tube. Relatively high D.C. potentials of 12,000 v. or more are generally employed, and the collection of suspended particles occurs on the tube walls. Single-stage precipitators are thus characterized by the collection of particles in the same electric field that produces the charged particles. During operation a countercurrent flow is set up so that while gas is passing through the tube or tube bank in one direction the dust or liquid collected on the tube walls falls or drains into a bin or similar collection unit at the tube base. Precipitators are usually installed so that fans pull rather than blow air through the units, and typical operating velocities are in the range of 300 to 500 ft. per minute (f.p.m.). The electrical power consumption of precipitators is relatively low, being of the order of 50 w. per 1,000 cubic feet per minute.

A typical two-stage precipitation process is illustrated diagram-

BY COURTESY OF ASSOCIATION OF IRON AND STEEL ENGINEERS
THE TWO-STAGE METHOD OF CLEANSING AIR BY COLLECTION OF IONIZED PARTICLES ON ELECTRICALLY CHARGED PLATES

matically in the figure. This type of precipitator is commonly called the plate type, and its operation may be enhanced by mechanical prefilters or perforated plates in order to ensure a uniform distribution of air. In a typical operation, dirty air is passed through a series of fine tungsten wires maintained at a positive potential of 12,000 v. D.C. This is called the ionizing step. The ionized particles then flow past a set of plates spaced about $\frac{1}{2}$ in. apart. Alternate plates are charged with a positive potential of about 6,000 v.

Upon contact with the negative collecting plates, the positively charged ions gain electrons and stick to the plates. The voltage on the wires in the ionizing chamber is regulated to secure as strong a glow as possible without passing over into the disruptive discharge; i.e., a spark or arc. The two-stage unit is used most frequently for dry dusts, and the gas flow is horizontal. Dust collected on the plates is either washed, blown or mechanically agitated into drains, bins or conveyers for easy removal.

Electrostatic precipitators for heavy-duty industrial applications differ in design but not in principle from the types of precipitators already described. Potentials of 25,000 to 100,000 v. D.C. are maintained in the operation of both single-stage and two-stage devices, although two-stage units with horizontal air flow are the commonest; air velocities range from 250 to 480 f.p.m., and mechanical filters for large particles are generally employed in series with the precipitation units.

Factors in Design.—Most units are designed with electrodes of opposite polarity spaced two to six inches apart. The size of the installation is determined primarily by the volume of gas to be treated and the amount of suspended matter to be removed, although in many cases the amount, type and size of the particles of suspended matter are of minor consequence. The air cleaners employed in ventilation, air-conditioning and heating systems usually must process air containing no more than four grains of suspended matter per 1,000 cubic feet. Industrial air and gas cleaners, however, frequently encounter loadings of 100 to 20,000 gr. per 1,000 cubic feet.

The materials of construction, including the collecting electrodes, vary from aluminum, iron and lead to reinforced concrete and vitrified earthenware, depending upon the composition and temperature of the gas stream to be processed. High-voltage equipment produces ozone and nitrogen oxides, and operating temperatures in excess of 370° C. (698° F.) are generally avoided. In comparison with dry filters, which in moderate-sized cleaning operations can be thrown away or cleaned, the high initial cost of electrostatic precipitators is generally offset by low maintenance costs.

Industrial Uses.—The earliest applications of the process were to the smelting and sulfuric acid industries. Precipitators at cement mills were fewer in number but handled large volumes of gas and large tonnages of precipitate. Other important applications are in the detarring of coke-oven gases, the cleaning of producer and iron blast-furnace gas, the cleaning of ventilating air in crushing, grinding and polishing mills (especially where cost of heating in winter makes recirculation of air important), the recovery of acid fumes in petroleum refineries and chemical plants, the recovery of dust from coal dryers and the removal of ash from the stack gases of large power plants burning powdered coal. On a moderate scale the process has also been applied successfully to the removal of bacteria from air in hospitals, doctors' offices and restaurants.

PREDESTINATION, the doctrine that God has eternally chosen those whom he intends to save. As the term is understood in modern usage, predestination is distinct both from determinism or fatalism and from the doctrine of divine providence, because it applies to the eternal destiny of man rather than to all the individual events of his life on earth. Thus one may teach that these events are subject to the free decision of man's moral will, but teach at the same time that salvation is due entirely to the eternal decree of God. In its fundamentals the problem of predestination is as universal as religion itself, but the emphasis of the New Testament on the divine plan of salvation has made the issue especially prominent in Christian theology.

Christian doctrines of predestination may be read as a series of glosses upon the words of the apostle Paul (Rom. 8:29–30):

For those whom he [God] foreknew he also predestined to be conformed to the image of his Son, in order that he might be the first-born among many brethren. And those whom he predestined he also called; and those whom he called he also justified; and those whom he justified he also glorified.

On the basis of these words, three types of predestinarian doctrine, although with many variations, have arisen in the history of Christian thought. One theory—associated with Semi-Pelagianism (*q.v.*), some forms of Nominalism (*q.v.*), and Arminianism (*q.v.*)—makes foreknowledge the ground of predestination, teaching that God predestined to salvation those whose future faith and merits he foreknew. At the opposite extreme is the doctrine of double predestination, commonly identified with John Calvin but more officially associated with the Synod of Dort, and appearing also in some of the writings of St. Augustine and Martin Luther and in the thought of Gottschalk and the Jansenists; according to this doctrine, God has determined from eternity whom he will save and whom he will damn, regardless of their faith, love, or merit—or lack thereof. A third doctrine—set forth in other writings of Augustine and Luther in the decrees of the Council of Orange (529), and in the thought of Thomas Aquinas—ascribes the salvation of man to the unmerited grace of God and thus to predestination, but attributes divine reprobation to man's sin and guilt. Pressed to their ultimate implications, however, all three types leave the mystery unanswered. For even if God bases his predestinating action upon his foreknowledge of faith and merit, such faith or merit is in turn dependent upon grace (*q.v.*), which God gives to some and not to others.

Thus the doctrine of predestination appears in Christian theology as a corollary of the doctrine of grace, protecting the freedom and sovereignty of God while at the same time declaring his love. Beyond this neither biblical revelation nor theological speculation provides a reliable guide. See also DETERMINISM; FREE WILL; *The Theological Problem*; and references under “Predestination” in the Index.

PREDICABLES, in scholastic logic, a term referring to certain relationships which may obtain between the predicate of a simple statement and its subject. The traditional list of these relationships is derived from Boëthius' Latin version of Porphyry's *Eisagoge* and consists of five items: genus, species, differentia, property and accident. It is based upon a similar classification set forth by Aristotle in the *Topics* (*a*, iv–viii), differing only by having species where the Aristotelian list has definition.

Aristotle's treatment of the matter is concerned only with statements of the form “A is B,” where the subject and predicate terms are both universal. He notes that in every true statement of this type the predicate will either be convertible with the subject (i.e., “B is A” will follow from “A is B”) or it will not. If the predicate is convertible with the subject and states its essence, then it is the definition of the subject; while if it is convertible but does not state the essence, it is a property of the subject. On the other hand, if the predicate is not convertible with the subject but is part of the definition, it is the genus or differentia of the subject, for a definition always consists of genus and differentia. Finally, if the

predicate is not convertible and is not part of the definition, it is an accident of the subject.

In attempting to understand these distinctions one is handicapped by Aristotle's failure to indicate clearly whether he is speaking of relations between linguistic expressions or between the meanings of such expressions. Thus, although definition is explicitly described as a phrase which means the essence, the remaining four predicables seem all to be treated primarily as non-linguistic.

Some Aristotelian examples may be briefly mentioned. In the true statement "Man is a rational animal," the predicate is convertible with the subject and states its essence. Therefore, "rational animal" is the definition of man. The statements "Man is an animal" and "Man is rational," while true, are not convertible. Their predicate terms, however, are parts of the definition and hence are the genus and differentia of man. On the other hand, the statement "Man is capable of learning grammar" is true and convertible, since all men are capable of learning grammar and whatever is capable of learning grammar is a man. But "capable of learning grammar" does not state the essence of man. It is therefore a property of man. For an example of an accident, take the predicate of the true statement "Man is featherless." This predicate is not convertible with its subject, nor is it part of the definition. Accordingly, it expresses only an accidental characteristic of man.

Porphyry gives the following examples: of genus, animal; of species, man; of differentia, rational; of property, risible; of accident, white. (B. Ms.)

PRE-ELEMENTARY EDUCATION. For the purpose of this discussion pre-elementary education is defined as education and training of very young children, i.e., children under compulsory school age or under kindergarten age. Kindergartens, which enroll children between the ages of five and six or seven years, have been rather generally accepted as an integral part of the primary school (see also **ELEMENTARY EDUCATION**). Thus in this article pre-elementary education means schools for children from two to four-and-a-half or five years or, more usually, for children between three and five. In western Europe and elsewhere there is some variation in the age of compulsory school entrance, the range being from five to seven years.

Historically, the training of children before they entered primary school was considered to be the sole province of the family. An occasional philosopher or educational reformer contemplated the possibilities of improved education of toddlers and young children but the early schools appear to have been philanthropic in purpose, established primarily as substitutes for home care rather than as supplements to the educational functions of the home. In general these early institutions were set up to provide custodial care, safety and health services to destitute and homeless children and those whose mothers could not care for them in the home. These institutions were frequently in the hands of religious orders. To some extent these generalizations still hold. However, as developments in medical science, psychology and education led to better understanding of the nature and needs of the young child (see **CHILD PSYCHOLOGY**), there was increasing concern for making provision for the optimum development of young children in all aspects of their growth—physical health, emotional security, social development and educative experience.

The writings and life work of Friedrich Froebel (q.v.) focused attention on the possibilities of educating children before the age of seven. In 1837 he opened the first kindergarten and demonstrated that children could learn through play and without formal instruction. Since Froebel's day other educators (e.g., Maria Montessori in Italy, Ovide Decroly in Belgium, Margaret McMillan in Great Britain, Harriet Johnson in the United States) have viewed the preschool years as a period of great educational possibilities. In the 20th century the preschool program came to be viewed increasingly as a desirable supplement to the home—as an agency that can give effective support to parents in the rearing of children as well as offer to the children themselves appropriate experiences that will contribute to harmonious growth and to a healthy, joyous and intellectually stimulating existence.

Wide and at times confusing variation is found in the terms used to describe the institutional arrangements for pre-elementary education. Such terms as infant school (Great Britain), nursery school and day nursery (Great Britain, U.S.), crèche and *école maternelle* (France), *casa dei bambini* (Italy), kindergarten (Germany, U.S.) are used, sometimes interchangeably, sometimes with quite precise meanings. These institutions are described in historical perspective in the sections which follow.

HISTORY

Great Britain.—In 1816 Robert Owen, a cotton mill owner in Scotland, founded a "preparatory school for infants" (age range of the pupils was from one to six years) where children were not to be given formal lessons but were to be permitted to play. His aim was "to prevent children from acquiring bad habits, to give them good ones, and to form their dispositions to mutual kindness." The idealism of Robert Owen and the enthusiasm of others in the years following resulted in the founding of many of these infant schools throughout the country and had an influence on the movement toward infant schools and day nurseries on the continent and in the United States. In time (1870) the infant schools became an integral part of the state system of education in Great Britain, the age of five being adopted as the age of entry to infant school and the age of three fixed as the minimum age at which children in attendance could count for a government grant. As the years passed the infant schools lost their "nursery" character and developed more and more a scholastic tradition in which little provision was made for physical activity, sleep and play. Children of three, four and five years were required to sit still in rows in large galleries—with arms folded and without conversing with one another—reciting lessons in which pictures and museum specimens took the place of living plants and animals and spending hours on the "three R's" and on needlework. Outside the official system, experiments in childhood education were being tried, notably the introduction of the views and methods of Froebel in the setting up of kindergartens for fee-paying pupils and the institution of schemes for the training of kindergarten teachers. The realization came gradually that enlightened and psychologically sound methods of early childhood education ought to be used with all children irrespective of parents' ability to pay fees, and out of this realization developed the British nursery schools. After 1918 such schools were a recognized part of the national school system with standards for nursery schools defined by law. Margaret McMillan and Grace Owen were pioneers in the movement to improve the health of young children and to provide a suitable environment for their growing minds. Both these leaders saw the nursery school as an extension of home life and as an institution which could improve through education the standard of home care of children. They further maintained that a nursery school is not a place for formal education but rather a community nursery where children up to the ages of five or six years may have appropriate opportunities for physical, mental and social growth through playing in small groups under the supervision of qualified teachers. Miss McMillan outlined a plan for a three-year course for training teachers for these schools, maintaining that only trained personnel should work with children of these ages. Training centres at Manchester (under Grace Owen), at London (under Lillian DeLissa) and at Deptford (under Margaret McMillan) supplied nursery teachers for the entire Commonwealth as well as for the early nursery schools in the United States. The older infant-school system was modified in the light of principles underlying the nursery school experiments, for the nursery school movement in England was from the first both vigorous and articulate.

Continental Countries.—Johann Friedrich Oberlin, an Alsatian Lutheran pastor, opened what was probably the first pre-elementary school in the western world. Beginning in 1779 he founded a number of schools for young children, which he called *écoles à tricoter* (knitting schools). These were philanthropic in purpose, with religious and moral training constituting their chief objectives. Crèches and *salles d'asile* were also being established about this time in the cities, more with the aim of protecting children from the dangers of the streets than of educating them. The

salles d'asile changed from private- to state-supported institutions in 1833 when they were made part of the national educational system. These establishments henceforth carried the designation of *écoles maternelles*. The objective of these schools is to work toward well-rounded development of the young child, without fatigue, restraint or force.

In Italy around 1835 a Catholic priest Abate Ferrante Aporti, working to establish elementary schools, became dissatisfied with the progress made by children and was led to investigate the conditions under which their preschool years had been passed. As a result he drew up a plan for the establishment of an infant school in which moral habits, intellectual cultivation and physical faculties were all to be emphasized. Early in the 20th century Maria Montessori (*q.v.*) began her experiments with children three to six years of age. She was a physician, who first became interested in the educational problems of mentally defective children but she soon became impressed with the learning potentialities of the normal preschool age child. Her first *casa dei bambini* was established in connection with a tenement-improvement project in Rome. In this school the children were given a special educational apparatus (*see* MONTESSORI SYSTEM). Self-education was the keynote of the plan; a large measure of individual initiative and self-direction characterizing the Montessori philosophy, the teacher would withdraw to the background and merely supervise the use of the apparatus, or "didactic material." This material was not designed to encourage children to play together. What opportunity there was for group activity occurred in connection with the housekeeping activities which the children shared: *i.e.*, keeping the rooms in order, serving the meals, etc. In 1928 Montessori was invited by the Italian government to institute a six-month training course in the use of her method for religious and lay teachers. In the latter years of her life she traveled extensively in Europe and Asia, and her ideas regarding the education of children under six had an important influence on the development of pre-elementary education in many parts of the world.

The United States.—Beginning around 1920 in the United States, nursery schools developed as the outcome of interest that may be traced to a variety of sources: (1) a scientific interest in early childhood, resulting from new applications in the fields of psychology and medicine; (2) a rapidly expanding background of educational theory; (3) experimental efforts in the fields of psychiatry, child guidance and parent education; and (4) the efforts of individuals and agencies to improve the educational programs of day nurseries already established for the care of children of working mothers. Two national emergencies (the economic depression of the 1930s and World War II) were also responsible for the further development and acceptance of nursery schools in the United States. Because the nursery-school movement sprang from such a variety of social forces, no one type of school may be singled out and described as representative of the movement.

Interest in systematic research into the abilities and development of young children increased rapidly after 1920 and a number of nursery schools were organized in universities to provide laboratories for the study of normal young children. Children two to six years of age were enrolled to furnish subjects for research, but soon it was recognized that such laboratories had an obligation to provide an educational program for the children enrolled and to demonstrate what good educational programs for preschool children entailed. Nursery schools were also established at this time as laboratories in which college girl students could study child care and development in preparation for their future roles as mothers. As more nursery schools were founded, colleges also instituted programs for the training of teachers. Prior to 1935 some nursery schools were also set up in conjunction with guidance clinics (as a parent-education effort) and in hospitals as an effort to encourage the recovery of the convalescent child.

The national emergency created by widespread unemployment and economic distress in the early 1930s resulted in the authorization of emergency nursery schools by the federal emergency relief administration. These schools were set up to provide jobs for unemployed teachers, nurses and affiliated workers and to

promote better morale among parents through fostering the physical and social well-being of their children. These nursery schools were under the control of the public school system, were for the most part housed in public school buildings and served to draw the attention of the general public to the desirability of school services for children below school age.

During World War II the number of employed women in the United States increased by more than 6,500,000 and many of these were mothers of young children. Federal legislation in 1942 made funds available to provide facilities for the day care of children whose parents were employed in industries necessary for war production. Supervision of these child-care projects was under local or state departments of education or welfare. When the war was over federal funds began to be withdrawn from these projects and by mid-1946 all federal support had been withdrawn. After that date there was no direct financial assistance from the federal government in support of schools for children under six.

Married women, however, continued to work in increasing numbers. Day nurseries (*q.v.*) for the care of children whose mothers work have long been provided under philanthropic auspices. Such centres try to meet the needs of children through group care, offering not only substitute mothering and dependable daytime care but also appropriate educational experiences.

Parent co-operative nursery schools (*i.e.*, schools operated by groups of parents who join together to make provision for their children to play together, sometimes hiring a professionally trained teacher and sometimes sharing among themselves the supervision of the children and other duties in connection with the school) were established in large numbers after World War II. There was a trend also toward church-sponsored nurseries and kindergartens, *i.e.*, weekday preschool programs operated in church buildings, some offering religious instruction to the children enrolled, others without emphasis on religious training and enrolling children from different religious backgrounds. There were also efforts to offer group experience to preschool children with handicaps of one type or another, for example, to children who are mentally retarded, who have cerebral palsy or are otherwise physically crippled, who are blind or deaf or who are emotionally disturbed. Sometimes this preschool experience is provided by forming small groups of children with similar handicaps and hiring teachers trained to give appropriate therapy to the children in addition to giving them a satisfying experience with peers and adults beyond the family circle. In many instances such schools are also centres for research in the educational problems of the handicapped.

MODERN THEORY AND PRACTICE

Preschool education may be viewed most correctly as an extension upward or outward of the home and family rather than an extension downward of the elementary school. The legitimate activities of the nursery school, as of the kindergarten, are those which supplement the mother's care and the home play of the child in fostering healthy physical and psychological development; they do not include borrowing from the elementary school or attempting to prepare the child for formal school before he is ready in terms of chronological age and physical and social maturity.

The nursery exists not to replace the home and primary school but to complement them. There comes a time in the young child's life when the resources of his home cannot provide all that is needed to stimulate the development of his potentialities—potentialities for learning new things through firsthand experience, for developing self-confidence and skill in making friends outside the family, for achieving a sense of himself as a person. It is believed that such learnings are useful in preparing a child for entrance into formal school and for the tasks he faces there in learning to read, write, cipher, etc.

The preschool years are said to be of supreme importance in molding the individual's personality, behaviour patterns and attitudes toward himself and others. This is an age of partial weaning from the emotional ties to the family, of the discovery of individuality and of the appearance of new interests, abilities and attachments. It is crucial, however, that ties to the family be

strengthened, not broken, and therefore one of the prime requisites of a preschool program is that it maintain a close relationship with each child's home and family. A school for the nursery ages must encourage individual development in relation to each child's personality, capacities and home environment.

The fulfillment of this task requires trained teachers with sound theoretical backgrounds and with practical experience under expert supervision in the guidance of young children. The teacher's task is to maintain, strengthen and enrich each child's personal relationship with his family and at the same time to introduce a wider world of people and opportunities. She must understand that entry into preschool creates a psychological problem for the young child as well as an opportunity for herself to make a contribution to his development. She must know how to provide a setting appropriate to the physical skills of the children and must understand normal phases of growth throughout the preschool years in order to be prepared for changes in the behaviour of her pupils, for fluctuations in dependence and independence, for confusion between right and wrong and fantasy and fact, so characteristic of these ages. She must have skill in helping children acquire gradually the capacity for harmonious relationships with other children. She must make the proper provision of satisfying activities in play and know how play of different types (dramatic, social, free, organized, artistic and creative) contributes to the flowering of the potentialities of the child and to the solving of his emotional problems. She needs an intuitive sensitivity to the learning problems of young children, for they are ordinarily unaware of their need for help and understanding.

A preschool program may be characterized by a threefold concern for optimum development: (1) physical health, (2) mental hygiene and (3) intellectual stimulation. Children under school age should not be brought together in a group unless the sponsoring agency can demonstrate its concern for good physical care which will result in healthy growth. This includes provision for adequate food, rest, cleanliness, the learning of health habits and some active outdoor play; it also entails concern for safety, watchfulness against accidents and protection against communicable diseases.

Of equal importance is an awareness of good mental hygiene. This involves an atmosphere characterized by affection, friendliness and noncoerciveness; simple rules benevolently enforced; success and praise for effort, which give a sense of achievement; respect from adults, so that children develop self-esteem and respect for others; support from the teacher in developing the capacity for co-operative relationships with others; steadiness and consistency in adults' expectations; and outlets in play for the strong feelings of the child.

Since one of the preschool's prime reasons for being is to offer children an educative experience, such a school must provide good teaching which results in the enjoyment of new experiences and of intellectual stimulation. This means planning a rich environment in the school, including stories and picture books; painting and clay modeling; observation of nature and pets; gardening and science; singing, dancing and rhythms; block building; play-house activities; games; and simple excursions outside the school. It is important that children engage in these experiences under the tutelage of an adult who understands their level of growth and their ability to comprehend, so that the activities are meaningful and enjoyable. It is believed that young children learn more readily from an active kind of *doing* through the medium of play than through formal lessons.

Common problems relating to pre-elementary education exist throughout the world. There is a shortage of trained teachers along with a lack of agreement as to what constitutes adequate training for teachers. In some quarters a gentle, affectionate disposition is considered sufficient for teaching little children, while in others a qualified teacher is expected to have completed several years of college and even to have postgraduate training. In general it may be said that educational standards are rather low for teachers of children under five or six years of age. Uniformly high standards for the operation of preschools are lacking and suitable housing and equipment are threatened by lack of financial

resources. There remains some reluctance on the part of citizens and government authorities to accept preschools as educational rather than welfare agencies.

On the other hand some responsible citizens in every country are concerned with providing children under school age with better health care, greater emotional security and richer educational opportunities. Although this concern does not extend to the entire child population, a beginning has been made everywhere.

PREESTABLISHED HARMONY, in the philosophy of Leibniz, constitutes the explanation of the coordination of change in substances which are not causally related.

Leibniz asserts for logical reasons that the universe consists of monads, indivisible substances which develop in time. Every characteristic of a monad (the events which happen to it being included among characteristics) is deducible from its own nature. There is thus no causal link between different monads. They are "windowless." Nevertheless everything happens as if by mutual influence, and Leibniz accounts for this by postulating that God created the monads in such a way that each represents the universe from its own point of view. The changes in them are thus necessarily coordinated.

The preestablished harmony was most highly valued by Leibniz as affording a solution to the mind-body problem posed by Cartesianism. Descartes's insistence on the complete qualitative difference between mind and body, together with his account of causation, made interaction impossible, although Descartes himself did not appreciate this. His followers, who were acutely aware of the difficulty, introduced the theory of occasionalism, by which the appearance of interaction is explained by the intervention of God on appropriate occasions. For Leibniz the mind is one monad and the body, a group of monads, so that the two are not completely disparate; but his theory of substance precluded him from allowing causal connection, and he substituted for the recurrent miracle of the occasionalists the single creative act of God by which harmony between monads is once and for all established. The term *harmonie préétablie* is first used in the *Explication du nouveau système* (1695), but the essentials of the theory are already present in the *Discours de métaphysique* (1686). See LEIBNIZ, GOTTFRIED WILHELM. (M. E. K.)

PREFECT (PRAEFECTUS), a title given in ancient Rome to an officer, civil or military, appointed by a magistrate as his deputy or subordinate.

1. A prefect of the city (*praefectus urbi*) was in the early republic appointed by the consuls when both were to be absent from Rome. When in 367 B.C. a praetor was instituted he took charge of the city in the consuls' absence, and a prefect of the city was henceforth appointed only for the annual Latin festival, when all the higher magistrates left Rome for a few days. The emperor Augustus revived the office in a new form, appointing a prefect of the city in 26 B.C. and again in 16 B.C. when he left Rome, although there were still a consul or consuls and praetors in the city. Toward the end of his reign, when owing to old age he took little part in public affairs, the office became permanent, even when he was himself in Rome, and it so continued under Augustus's successors. The post was given, normally for life, to a very senior senator. The prefect commanded the urban cohorts and was responsible for the maintenance of law and order in the city. He acquired a police jurisdiction, which developed into a full criminal jurisdiction, extending to the hundredth milestone from the city. Under the later empire the prefect became responsible for the entire government of Rome. The post was normally assigned to members of the great aristocratic families, and was held for a

brief term only (about a year). It ranked very high in official precedence, immediately below the praetorian prefects. In A.D. 359 a similar prefecture of the city was instituted for Constantinople.

2. Two praetorian prefects (*praefectus praetorio*) were appointed by Augustus in 2 B.C. to command the praetorian guard. The post was thereafter usually assigned to a single man, sometimes shared between two; the holders were almost invariably of equestrian rank. The praetorian prefect, being responsible for the safety of the emperor, rapidly acquired great power, and his office became the summit of the equestrian career. Many were virtually prime ministers to the emperor, and some ruled the empire in the name of a weak emperor. Two, Marcus Opellius Macrinus (q.v.) and Marcus Julius Philippus (see PHILIP the Arabian), seized the throne for themselves. The functions of the office were ill-defined. Praetorian prefects occasionally were given the command of armies; Cornelius Fuscus, for instance, was commander of the Roman forces in Domitian's Dacian War. They also acquired important judicial functions as delegates of the emperor; in the Severan period several eminent lawyers—Papinian, Ulpian, Paulus—held the office. In the late 3rd century, the praetorian prefect also acquired functions of a financial character; for as the money revenue dwindled owing to the inflation of the currency, and requisitions in kind were used to supply the court, army, and civil service, it was the praetorian prefects who as quartermasters general to the emperor directed and organized these requisitions.

Under Diocletian each emperor had his praetorian prefect, who combined military, judicial, financial, and general administrative functions. He was a chief of staff and adjutant general, controlling the discipline and recruitment of the armies, and often assuming the supreme command. He was, next to the emperor himself, the supreme judge, receiving appeals from the courts of provincial governors; his sentences were declared by Constantine to be inappellable. He organized the indiction (q.v.), the taxation in kind which supplied the bulk of the empire's needs. Through his deputies (*vicarii*) he controlled the provincial governors. Constantine by the creation of the *magistri militum* deprived the praetorian prefects of their military powers, but they retained their judicial and financial functions and remained the highest officers of the empire. The three sons of Constantine had each a prefect but when Constans conquered Constantine II he kept two prefects, and when Constantius II reunited the empire he retained three prefects or sometimes four. From 395 four territorial prefectures became stabilized: of the Gauls (Britain, Gaul, the Seven Provinces, and Spain); of Italy (Pannonia, Italy, the city of Rome, and Africa); of Illyricum (Dacia and Macedonia); and of the East (Thrace, Asiana, Pontica, Oriens, and Egypt). When Justinian reconquered Africa he created a separate praetorian prefecture for it.

3. An equestrian prefect of the corn supply of Rome (*praefectus annonae*) was appointed by Augustus toward the end of his reign. The office continued into the later empire, when Constantinople also acquired its *praefectus annonae*.

4. An equestrian prefect of the fire brigade and night watch of Rome (*praefectus vigilum*) was appointed by Augustus in A.D. 6. This office also survived in the later empire, and was transplanted to Constantinople.

5. Equestrian *praefecti vehiculorum* were instituted, probably by Hadrian, to manage the public post in Italy and the provinces.

6. When Augustus annexed Egypt, he did not put it under a governor of senatorial rank, since he feared to place a possible rival in control of a province so rich, so militarily impregnable, and so vital for the corn supply of Rome, but appointed an equestrian prefect (*praefectus Aegypti*) with the powers of a proconsul; he commanded three legions. Under Diocletian's reorganization the prefect of Egypt became merely civil governor of one of the three provinces into which Egypt was divided, but under Valens, when Egypt became a separate diocese, the title of *praefectus Aegypti* was given to its civil administrator.

7. Augustus appointed equestrian prefects to govern small but turbulent areas, such as the Alpine districts, Raetia or Corsica.

The title was replaced by that of procurator under Claudius. Septimius Severus placed Mesopotamia with its two legions under an equestrian prefect.

8. Under the republic judicial prefects (*praefecti iuri dicundo*) were appointed by the urban praetor to administer justice in the towns of the Roman territory. Four of these (*praefecti Capuam Cumas*) were by exception elected by the assembly from 211 B.C.

9. Consuls and praetors (and proconsuls and propraetors) appointed an equestrian *praefectus fabrum*, originally a chief engineer, later a chief of staff. They also appointed *praefecti* to command allied contingents and fleets. Under the principate the equestrian commanders of auxiliary cavalry units were styled prefects (*praefectus alae*), as were the commanders of the fleets (*praefectus classis*). Each legionary camp had a quartermaster styled *praefectus castrorum*, usually a former centurion. In Egypt the legions were commanded by equestrian *praefecti* instead of senatorial *legati*, as were the Mesopotamian legions under Severus. From the reign of Gallienus, when senators were generally excluded from military commands, prefect became the normal title of legionary commanders.

10. Various senatorial commissioners instituted by Augustus bore the title of prefect. Such were the two *praefecti aerarii Saturni*, who managed the treasury from 28 to 23 B.C. and again from A.D. 58; the three *praefecti aerarii militaris*, who managed the military treasury established in A.D. 6; and the *praefecti frumenti dandi*, responsible for the distribution of the corn dole in Rome. From the time of Trajan or Hadrian there were also *praefecti alimentorum*, who managed the funds for the maintenance of children in the various regions of Italy.

On the praetorian prefect see L. L. Howe, *The Praetorian Prefect from Commodus to Diocletian* (1942); J. R. Palanque, *Essai sur la préfecture du prétoire du Bas-Empire* (1933). On the prefecture of the city of Rome in the later empire, see A. Chastagnol, *La préfecture urbaine à Rome sous le Bas-Empire* (1960). (A. H. M. J.)

PREFECT (FRENCH). A prefect (*préfet*) in France is a high government official. A similar official (*praefectus*) existed under the Roman Empire, and in France a comparable official (*intendant*) existed under the *ancien régime*. The French prefectural corps was created in 1800 by Napoleon, who raised it to a position of great prestige and influence. The prefects were the administrators of the *départements*; they were responsible for public order, for good government, and for ensuring that the central government's policy was effectively carried out throughout the country. Napoleon called them *empereurs à petit pied*.

Under succeeding regimes the power of the corps increased but its prestige declined. Dependent for office on the whim of the government, the prefects became primarily concerned with police and elections, and one of their principal functions was to ensure the government a safe parliamentary majority. They reached the height of their power under the Second Empire. During the first decades of the Third Republic the prefects' position was weakened by the frequent nomination of new men by successive governments. However, prefects then became increasingly concerned with social and economic problems, and after World War II, while retaining responsibility for public order and good government, they became the dynamic element in the provinces for promoting and coordinating social policies.

In addition to the prefects, each of whom was responsible for a *département*, the prefectural corps in the 1960s consisted of secretaries-general, who were second in command; subprefects, who were responsible for the *arrondissements*; and *chefs de cabinet*, who were the prefects' personal assistants. Under the 1958 constitution (art. 13) prefects were appointed by the president of the republic with the approval of the council of ministers and on the recommendation of the minister of the interior, to whom they were responsible. They could be dismissed at any time without cause or notice, but in the second half of the 20th century they enjoyed in fact considerable security of tenure. Sweeping changes were likely only when there was a major change of political direction or regime.

Conditions of service in the corps were laid down in a special statute of June 19, 1950. A prefect has a wide variety of powers

accrued haphazardly over the years; according to one estimate there are as many as 4,000 separate sources of his legal authority. The prefect is constitutionally responsible for "coordinating the activities of state officials, the representation of national interests, and the administrative supervision of local authorities." He is the sole legal representative of the government and the state in the *département*; when a minister delegates his powers, he is required by law to delegate them to the prefect and not directly to his own officials in the field. The prefect, therefore, acts as the agent through which all powers are transmitted from the centre to the periphery.

The prefect is the general administrator of the *département*, the chief executive officer of the elected departmental authority (the *conseil général*), the principal police authority, and the supervisor of the communes in the *département*. His approval is required for many administrative acts of local authorities.

In Paris the prefect of the *département* of the Seine also exercises the municipal powers normally possessed by the mayor of a commune, there being no popularly elected mayor of Paris. There is, in addition, a special prefect of police whose jurisdiction covers the whole Paris conurbation. (B. CN.)

PREGL, FRITZ (1869–1930), Austrian chemist who received the 1932 Nobel Prize in Chemistry for his work on the microanalysis of organic substances, was born in Laibach on Sept. 3, 1869, and was graduated from the *Gymnasium* in that city. He received his M.D. degree from the University of Graz in 1894. After teaching in the Physiological institute at Graz for several years, he went to Leipzig in 1904, where he studied methods of physical chemistry with Wilhelm Ostwald and then went to Berlin where he worked with E. Abderhalden. He returned to Graz in 1904 as professor of physiological chemistry at the Medico-Chemical Institute. During the year that followed he investigated the components of albuminous bodies and the analysis of bile acids. From 1910 to 1913 he was professor at the University of Innsbruck, returning to Graz in 1913 as director of the Medico-Chemical Institute.

Lack of material in Pregl's work with bile acids had impelled him to look for methods requiring smaller amounts when making quantitative analyses of elements in compounds. By 1912 he was able to make measurements of carbon, hydrogen, nitrogen, sulfur and halogen, using only 5 mg.–13 mg. of starting material with results as accurate as those obtained by existing methods. Later he perfected his techniques so that as little as 3 mg.–5 mg. were adequate for measurements at least as exact as the results of macroanalysis. The development of chemical microanalysis (see *CHEMISTRY: Microanalysis*) marked a great advance in organic elementary analysis. In addition to the general factor of economy, it became indispensable in many research problems of pure science, physiology, medicine, and industry. Pregl also contributed a number of micromethods for measuring atomic groups and a sensitive microbalance. In 1917 he published *Die quantitative organische Mikroanalyse* (6th ed., 1949), a monograph. Pregl also perfected the Abderhalden dialysis test for the presence of enzyme, so that less serum was needed for a reaction; invented a simple method for determining the functional capacities of the kidneys; and added to medicine an iodine solution, named for him, which is a mild but effective antiseptic. He died at Graz on Dec. 13, 1930.

PREGNANCY. Life has its beginning in the egg cell or ovum. These minute cells, which measure about $\frac{1}{16}$ in. (0.2 mm.) in diameter, are contained in the two ovaries, which lie in the abdomen, one on either side of the uterus (womb). During healthy reproductive life one ovum is shed each month from one or the other ovary (ovulation) about the middle (12th–14th day) of a menstrual cycle. Average cycles—measured from the first day of one period to the first day of the next—occupy 28 days and in health are regular within a day or two. For each day that the period is prolonged beyond the average 28 days, ovulation is delayed for one day, so that if the cycle is 32 days, the ovulation will be between the 16th and 18th days. Expressed in other words, ovulation tends to occur about 14 days before the next period regardless of the interval between the periods. After being shed the ovum enters the Fallopian tube, along which it

passes to the uterus. If it is not fertilized it succumbs quickly. Since the sperm cells also have a short maximum life-span (two–four days), though somewhat longer than that of the ovum, it thus follows that there is only a short critical interval in the cycle during which fertilization is possible; on either side of this critical period is an interval when intercourse is unlikely to be fertile (the so-called safe period). If the ovum is not fertilized it escapes in the next monthly loss of blood. If it is fertilized by a sperm cell (spermatozoon), pregnancy has begun.

Reproductive Physiology.—A brief summary of some matters of reproductive physiology is essential for an understanding of the complex changes which occur during pregnancy. The first of the complex changes which occur during pregnancy. The first factor is the pituitary gland (*q.v.*), the front part of which (the anterior pituitary) plays a dominant role in the initiation and maintenance of the rhythmic functions of the sexual glands and breasts in the female and of the sex glands in the male. It is also concerned with the functioning of the thyroid and adrenal glands. Specific hormones of the anterior pituitary are responsible for the periodic functioning of the ovary and the rhythmic shedding of ova. The pituitary energizes the ovary to produce hormones (estrogen and progesterone) which prepare the uterine bed for the reception of the ovum should fertilization occur, preparations which in the nature of things are only relatively rarely required.

During reproductive life the ovaries shed between them from 300 to 400 ova. The ovary through its hormones controls the imbedding of the fertilized ovum in the uterine wall, and this control continues for about 12 weeks, after which it is taken over by the placenta (*q.v.*), the organ through which the embryo draws its nourishment from the maternal blood. Its vessels ramify freely around the uterine vessels in the placenta, where there is a constant diffusion of nutritive elements from maternal to fetal blood and of waste products in the opposite direction. The fetal blood passes to the placenta along the two arteries in the umbilical cord and, after it has been replenished and purified, it passes to the fetus via the umbilical vein. In addition to these combined nutritional and excretory functions the placenta takes over the hormonal functions which are in large part abdicated by the pituitary and ovaries.

A special anterior pituitary hormone (prolactin) acts on the breasts and stimulates the production of milk. Prolactin is produced in large amounts after labour, and its production continues as long as the infant is suckled. The hormonal mechanism by which the active secretion of milk from the breast is delayed till after labour is not well understood. There is some reason for the view that so long as the hormones of the placenta (estrogen and progesterone) are circulating in the blood the lactogenic influence of prolactin is inhibited and that this inhibition is not removed until the placental hormones are excreted in the days following labour. (See also *HORMONES: Ovarian and Placental Hormones*.)

Among the other physiological changes that are evoked by pregnancy one of the most important is an increase in weight. On the average a pregnant woman gains 24 to 28 lb. (10.9 to 12.5 kg.) but there are wide differences; some women enjoying apparent health may gain much less, others much more. The organs of reproduction—the uterus and its contents and the breasts—contribute an average of 11 lb. (5 kg.) to the total increase in weight. Under normal conditions the weight increase in pregnancy is quickly lost after labour, but in some instances this does not occur, and many women retain their weight gain and may even acquire active obesity dating from childbirth.

A considerable part of the normal weight gain of pregnancy is due to the retention in the body of water which is required for the increase in the total volume of the circulating blood; by the 36th week of pregnancy the total amount of blood in the heart and the blood vessels is increased by about 30% over that in the nonpregnant state. The greater part of this increase is used up in filling the greatly expanded arteries and veins of the womb. The solid elements of the blood—the red blood corpuscles carrying the hemoglobin—are also increased, but not to the same degree. While the fluid part of the blood (the plasma) is increased by

40%, the red blood cells are increased by only about 15%; the result is the so-called physiological anemia of pregnancy.

Duration of Pregnancy.—There is a small but appreciable elevation of the body temperature at the time of ovulation, and this, by pinpointing the date of ovulation, has provided a method of determining the interval between ovulation and childbirth. Usually this lies between 266 and 270 days, with extremes of 250 and 285 days. The usual method for determining the date of childbirth is to add seven days to the first day of the last menstrual period and count forward nine calendar months. Thus, if the last period began on March 10, the estimated date of childbirth is Dec. 17. This gives a figure of roughly 280 days or ten lunar months. As ovulation occurs about the 14th day of the cycle, it follows that this estimate is in reality about 14 days longer than the true average duration of pregnancy as estimated by the temperature method.

Not infrequently the law courts are required to pronounce on the legitimacy of a child born after an interval that is greatly in excess of the average figure or, on the other hand, that is much shorter than this figure. Some countries recognize upper and lower limits.

Diagnosis of Pregnancy.—A woman normally recognizes that she is pregnant by the cessation of menstruation (amenorrhea; see MENSTRUATION), and within a short time this is confirmed by the increasing swelling of the abdomen. But menstruation may cease and the abdomen increase in size apart from pregnancy, and the doctor often has to adopt other criteria for his diagnosis.

There are, indeed, only three unmistakable signs of pregnancy. The first is the hearing of the fetal heartbeat, which is audible beginning about the 16th to 18th week of pregnancy. It is heard by placing a stethoscope on the lower abdomen; the sound resembles in quality the ticking of a watch beneath a pillow. At the sixth month its rate is 150–160 per minute, while at the end of pregnancy it is 120–140. The second positive sign, the demonstration of the fetal skeleton by X-ray examination, is possible by the 16th week, when the fetal bones are visible, but such an examination is rarely required and should not be made routinely. The third positive sign is the recognition of the kicking movements of the fetus, usually noticeable by the 18th to the 20th week. By this time the woman often feels the movements herself; this is the so-called "quickening" that reveals to the mother that her pregnancy has reached its halfway stage.

There are several probable signs and symptoms of pregnancy. Amenorrhea, however, can occur apart from pregnancy in anemia, chronic infections such as tuberculosis, or after mental shocks; e.g., the mental shock associated with the death of a relative, or the anxiety of a woman who has exposed herself to the risk of pregnancy. There is a reverse of this latter condition in false pregnancy (pseudocyesis), when a childless woman with a fervent desire for motherhood develops, though she is not pregnant, the signs and symptoms of pregnancy, such as amenorrhea and increasing size of the abdomen; at the end of the term, she may actually go into "labour."

Nausea, with or without vomiting and usually more evident in the morning ("morning sickness"), is a common symptom. It generally occurs between the 6th and 12th week of pregnancy. In some women it is such a constant feature in pregnancy that they regard it as a sure sign of their state. The sickness is sometimes associated with the development of an acute dislike of some ordinary article of food. (An unusual craving for certain foods may occur in the latter part of pregnancy.) Morning sickness in some cases may be severe enough to require hospital treatment.

A sense of fullness in the abdomen is often felt from the early weeks, and by the end of the third month the uterus can be felt where it rises from the pelvis. It reaches the level of the navel about the fifth lunar month. In the last weeks there is commonly a sinking down of the womb when the woman may feel more comfortable from relief of pressure ("lightening").

Enlargement and tenderness of the breasts are especially evident in women pregnant for the first time (primigravidae). In women who have had a previous pregnancy these changes are

"DORLAND'S ILLUSTRATED MEDICAL DICTIONARY," 23RD EDITION, PHILADELPHIA, W. B. SAUNDERS COMPANY

UTERINE LEVELS DURING PREGNANCY

often less evident, though in the second half of pregnancy there is in most women a marked dilatation of the superficial veins and there is fluid in the breast which can be easily expressed from the nipple. In many women, especially brunettes, there is a dark pigmentation of the area around the nipple, which deepens with the advance of pregnancy. Pigmentary changes in other parts of the skin are sometimes found; e.g., the abdomen, where there is often a dark streak (linea nigra) extending from the pubic hair upward as far as and, sometimes, beyond the navel, while some women develop areas of pigmentation on the face, especially the forehead. This pigmentation is believed to be due to stimulation of the pigment cells by secretions of the anterior pituitary.

As the result of stretching of the abdominal walls there are often formed the striae gravidarum (pinkish or purple streaks) where the superficial and less active layer of the skin has failed to keep pace with the generalized stretching of the abdominal wall. The streaks mark where the deeper and more vascular areas are thus exposed.

Further evidence for the diagnosis of pregnancy is gained by internal examination, by which the physician can find enlargement of the uterus as early as the eighth or tenth week.

Biochemical tests for pregnancy depend upon the fact that chorionic gonadotropin or HCG, one of the hormones produced by the placenta, is excreted in the urine of the pregnant woman. When a small quantity of urine containing HCG is injected under the skin of female mice it produces characteristic changes in the ovaries of the animals. Young virgin mice so treated are killed at the end of 100 hours and the test is positive if characteristic "blood points" are present in the ovaries. The method, called after its inventors the Aschheim-Zondek test, is accurate in 98% of cases and may reveal a pregnancy that has advanced only four days beyond the first period missed. At such an early stage, however, the output of hormone may be small and it is better to wait for a further two or three weeks before having recourse to the test.

Toads or frogs are also commonly used in pregnancy testing. In a male frog the injection of urine containing HCG is followed

after three hours by the ejaculation of spermatozoa, which are detected by the microscope. In the female toad a positive result, consisting of the extrusion of one or more ova recognizable by the naked eye, is obtained in 18 hours. Individual toads and frogs can be employed repeatedly for testing.

Antenatal (Prenatal) Care.—This includes the continuing supervision of the general health of the woman, the detection of any condition that may necessitate special attention at the time of birth (e.g., contraction of the pelvis), and the detection and treatment of any abnormal state that may develop during pregnancy. In addition it provides the opportunity for establishment of that confidence between the woman and attendant that is peculiarly important in obstetrics. Finally, the occasion is taken to discuss the preference of the woman in regard to the place of confinement, whether home or hospital. Since the 1930s there has been an increase in hospital beds to meet both the marked rise in the demand by women for hospital care and the increasing awareness of the health authorities of the importance of hospital care in obstetrical abnormalities. Women with a primary claim on the hospital services for their delivery include most primigravidae; those whose previous labours have been abnormal; women whose homes are unsuitable; women who have had several previous births; and those who, during the course of pregnancy, develop an unexpected abnormality that requires special attention.

Periodic Examinations.—The principle underlying antenatal care is the medical examination of the pregnant woman at periodic intervals throughout her pregnancy. At the first examination, made preferably at an early stage of the pregnancy, a full medical history is obtained. The details of any previous pregnancies (e.g., difficulty at the birth and toxemia), the date of the last menstrual period, and the expected date of the confinement are noted. A physical examination is made, including the recording of the weight and blood pressure. The urine is examined for abnormal constituents, especially albumin and sugar. The heart and lungs are examined and a sample of blood is removed from a vein to be tested for anemia, for syphilis (Wassermann test), and for the Rhesus and ABO grouping (see below). The next examinations are generally made at four-week intervals up to the 30th week, at three-week intervals to the 36th week, and weekly from then onward. At each of the later examinations the weight, blood pressure, and state of the urine are recorded, and the abdomen is palpated to determine that the position of the fetus in the womb is correct, for at this stage a faulty position often can be rectified. Excessive enlargement of the abdomen may indicate twins, which will demand special care at the delivery; or there may be excessive fluid in the womb (hydramnios). At the 34th week an estimate of the pelvic shape and size is made with special reference to the discovery of any contraction that may require special care at birth or, in a severe abnormality, Caesarean section (*q.v.*).

Nutrition in Pregnancy.—The diet of a pregnant woman should contain 2,400–2,500 calories (*i.e.*, 400–500 more calories than are in the diet in the nonpregnant state) and that of the nursing mother should contain 3,000 calories. In general a woman who is ordinarily accustomed to a well-balanced diet will not require adding more to this regimen than is dictated by the normal, steady increase in appetite that is especially marked from the third month onward. (See NUTRITION.) Such a diet will contain red meat, eggs, and seafood two or three times weekly; and green vegetables, fresh fruit, and at least one pint of milk daily.

Drugs Harmful in Pregnancy.—Until the late 1950s it had been assumed that the fetus was adequately protected from the effects of drugs given to the mother during pregnancy. Events have shown that this is not so; the fetus is peculiarly sensitive to damage during the first 12 weeks of its existence. There is evidence that a large number of drugs, if given during this period, are capable of causing malformations. The most dramatic episode of this type was the production of phocomelia ("seal limbs") in the infants of mothers who had taken thalidomide as a sedative or anti-emetic during early pregnancy. The main deformities in this condition are a shortening or absence of the limbs; important associated defects include absence or malformation of the external ear, fusion defects of the eye, and absence of the normal openings

of the gastrointestinal tract. It was estimated that between 2,000 and 3,000 such babies were born in West Germany and 500 in Great Britain between 1959 and the beginning of 1962. In the U.S., thalidomide never was distributed for clinical use. (See also MONSTER.)

Another group of drugs harmful in pregnancy is the androgenic (masculinizing) compounds, which have produced in female infants external genitalia showing a variable degree of deviation toward the male type of anatomy. Not only will frankly androgenic drugs such as testosterone produce this effect, but also those with androgenic side effects; for example, the anabolic steroids, and many of the compounds with a progesterone-like activity which are used in threatened or habitual abortion.

Cortisone and related drugs given to experimental animals in early pregnancy will produce cleft palate in the offspring, but this has only rarely occurred in man. However, a transient depression of adrenal function in the mother may occur in the neonatal period (the first 28 days following birth) if she has been receiving large doses of cortisone throughout pregnancy.

After the early 1960s greater care was exercised in the screening of new drugs before they were considered safe for clinical use in pregnancy. The screening included, among other things, tests on pregnant animals of a number of species.

Toxemias of Pregnancy.—Among the most prominent of the abnormal conditions that make the periodic examination essential are the toxemias. They are of two kinds. The commoner is pre-eclampsia, which, unless recognized early and vigorously treated, may pass into a grave, convulsive form (eclampsia). The other kind is characterized by severe and persistent vomiting (hyperemesis gravidarum). Because of their superficial resemblance to a toxic state, these diseased conditions have been classified as toxemias, despite the fact that in neither case has intensive research revealed the existence of a causative toxic agent.

Preeclampsia usually develops insidiously in the latter half of pregnancy. The first sign may be a swelling of the ankles and legs and sudden increase in weight, but, while they should always arouse suspicion, these signs are often present without toxemia. Commonly the first significant sign is an elevation of the blood pressure, detected at a routine antenatal visit. The presence of albumin in the urine is the second most important sign.

In the milder forms of toxemia ambulant home treatment, consisting of rest, is often permissible on the understanding that the patient visits the clinic or is seen by a doctor or midwife at short intervals. Where the initial signs are marked or where there is a progressive worsening of the state, the patient is admitted to a hospital or nursing home. In the graver manifestations termination of the pregnancy is called for in the interest of both mother and child.

Rhesus Factor.—One of the reasons for an examination of the pregnant woman's blood at the first antenatal visit is to determine her blood group. About 85% of Caucasians, and almost all non-Caucasians, contain in their blood an antigen similar to that present in the Rhesus monkey and are therefore classed as Rhesus positive (Rh+); the remaining 15% of Caucasians have no such antigen and are classed as Rhesus negative (Rh-). If the father is Rh+, the baby may be Rh+; if, in such a case, the mother belongs to the Rh- group, the bloods of mother and baby are "incompatible." In the placenta the Rhesus antigen passes into the maternal blood and stimulates the formation in the mother of antibodies which enter the fetal circulation and destroy the red blood cells by agglutination and hemolysis, with the production of anemia or jaundice or both (erythroblastosis fetalis). The risk is small during a first pregnancy, unless the mother has by mischance previously received an incompatible transfusion; *i.e.*, of Rh+ blood. With each succeeding pregnancy in which the fetus is Rh+ the antibodies in the mother's blood increase, and with it the risk to the fetus. In cases where the woman's blood is Rh- the husband's blood group is determined; if it is positive the woman's blood is tested for antibodies monthly from the sixth month onward. Where the child is erythroblastotic the sole effective treatment is the replacement of the child's blood by compatible blood from a donor. Mother-fetus incompatibility similar

to that found in the Rhesus blood group occurs with other types of antigen; e.g., the ABO group. (See BLOOD GROUPS.)

Exercise and Relaxation.—Walking in the open air should be a daily routine for the pregnant woman, but too long walks or exhausting exercise of any kind should be avoided. Women vary greatly in these respects, and any advice given is weighed against the woman's natural habits. Much can be said in favour of the so-called relaxation classes organized in relation to antenatal clinics. These classes are a valuable addition to the educational functions of the clinic. There the care of the body can be discussed and the facts of labour explained, so that the expectant mother is encouraged to forsake her fear and to adopt a more confident attitude toward pregnancy and labour.

PRE-HELLENIC ARCHITECTURE. This article deals with the architecture that developed around the Aegean sea and in the near east from earliest times through the Archaic period of Greece (6th century B.C.). The architecture of the subsequent period is discussed in GREEK ARCHITECTURE. Though belonging within the greater context of this discussion, the architectural history of Egypt will be found in EGYPTIAN ARCHITECTURE.

The maritime kingdom of Crete, by virtue of its central position between Europe, Asia and Africa, had early contacts with Egypt and the ancient near east and seems to have played an important intermediary role in the transmission of architectural influences to Greece. It is for this reason that near eastern architectural development is included here. The architecture of Achaemenid Persia, contemporary to early Greek architecture and therefore not strictly speaking pre-Hellenic, is included here also for the sake of geographic unity.

Since the chronology of pre-Hellenic times in the regions discussed in this article is subject to controversy, the dates given here are not necessarily identical with those given in other articles. In each case the author's dates are used. For further historical information see the articles about the specific places involved (e.g., BABYLONIA AND ASSYRIA; CRETE; etc.).

MESOPOTAMIA

Mesopotamian civilization was theocratic; consequently it is in religious buildings that the architecture of this region finds its earliest and fullest expression. (See BABYLONIA AND ASSYRIA.) The beginnings of mud-brick architecture in the Ubaid period (4th millennium B.C.) may be seen in the earliest temples at Abu Shahrain in the south of Mesopotamia and Tepe Gawra in the north. Platforms, buttresses and recessed portals, perennial traits of Mesopotamian architecture down to the Hellenistic period, were already established at both sites. A recessed portal is part of the entrance façade of the earliest temple at Tepe Gawra, and at Abu Shahrain a similar building was placed on a platform and approached by a flight of steps.

These characteristics were repeated at Uruk (Erech, mod. Warka), with the added development that the platform of Abu Shahrain was replaced by the ziggurat (*q.v.*), a tall staged tower with outside staircases and a shrine at the top.

Walls and columns of early Mesopotamian temples were covered with a patterned facing of coloured clay cones that were inserted into the mud plaster; this primitive decorative technique gave rise to the later Assyrian practice of covering entire walls with richly polychrome glazed and molded brickwork. The arch was

used in Mesopotamia, and false, or corbeled, vaults (*i.e.*, vaults constructed of successive series of projecting courses) were occasionally employed for tombs.

The transition to the Early Dynastic period (*c.* 3000–2340 B.C.) brought with it certain innovations. The plano-convex brick, flat on one side and curved on the other, was invented. Both religious and secular buildings were built around a central court; the entrances to temples were generally flanked by towers and approached by a stairway.

The oval temple precinct at Khafajah is a typical example of Early Dynastic architecture. There, as at Abu Shahrain, the whole layout was elevated on a low platform. A flight of steps led up to an outer gateway flanked by two high towers. A small forecourt led to another gate which opened upon a spacious inner court, containing a well, several shallow ablution basins and the sacrificial altar. The temple proper, which probably had buttresses and recessed walls, was placed on a second platform approached by another flight of steps. Basically, this is also the type of complex at Tell Asmar and Tell Agrab. Later the square or oblong plan became more common.

Little is known about the architecture of the Akkadians, a Semitic dynasty which assumed power over Mesopotamia in the middle of the 3rd millennium B.C. This dynasty was ousted by the Guti, who were, in turn, driven out of Mesopotamia by the Sumerians at the end of the 3rd millennium, which began a time of great architectural activity.

The city of Lagash (mod. Telloh) flourished under King Gudea, but few remains of his architecture have come to light. Ur-Nammu, the first king of the 3rd dynasty of Ur (*c.* 2250 B.C.), erected a great ziggurat at Ur, his capital. It stands within an oblong court and is oriented to the points of the compass. Buttresses on its outer face give it added strength. Three monumental stairways with bastions in their angles converge at the first stage from which a single stairway ascends to the top of the second stage. A temple no doubt crowned the summit of the structure, but this has disappeared without a trace.

The 3rd dynasty of Ur is also represented by buildings at Uruk, Nippur, Mari (mod. Tell el Hariri), Ashur and Tell Asmar. The temple-palace of Gimil-Sin at Tell Asmar deviates little from the development already described. The temple portion of the complex consists of a square central court, with the cella at the far end, surrounded by massive buttressed walls and entered by a towered gateway. The palace of the local ruler joins this temple at an angle and consists of antecella, cella, central court, throne room and great hall. Surrounding these large ceremonial spaces were small administrative offices; the living quarters seem to have been situated on a second floor.

Ur fell early in the 2nd millennium B.C., and the succeeding phase is known as the Isin-Larsa period (2025–1763 B.C.). The temple of Ishtar-Kititium at Ishchali belongs to this period. Although related to, and developed from, the Early Dynastic complex at Khafajah, the original single-chambered shrine at Khafajah was there elaborated into an architectural complex with forecourt, court and cella.

A palace at Mari has been tentatively identified with the reign of Hammurabi (1792–1759 B.C.), the ruler and lawgiver of the 1st dynasty of Babylon which flourished contemporaneously with Isin and Larsa to the south.

A foreign dynasty, the Kassites, invaded southern Mesopotamia in about 1600 B.C. Their accession to power inaugurated a new era of building activity at Ur, Uruk and Dur-Kurigalzu, the new capital 20 mi. to the west of modern Baghdad.

While the Assyrians in general adhered closely to established architectural schemes, they also brought about several important deviations from the early Mesopotamian norm. The latest Ishtar temple at Ashur and the Ashur temple at nearby Tukulti-Ninurta, built during the reign of Tukulti-Ninurta I (*c.* 1250–1210 B.C.), established the type that became characteristic for Assyrian temples.

The Ashur temple at Tukulti-Ninurta was built against a ziggurat, as at Mari, and incorporates a dual entrance system: one entrance faces the cella as in earlier buildings; the other enters

at a right angle. The cella is on a podium that lies in front of a recess cut out of the body of the ziggurat, and the ziggurat itself no longer incorporates a staircase. The practice of setting a series of stone slabs, called orthostates, at the bottom of a wall below the mud-brick upper parts became common in the Assyrian period and was seen again in Hittite architecture.

During the Late Assyrian age (c. 1000–612 B.C.), Ashur, Babylon, Nineveh, Nimrud, and Dur-Sharrukin (mod. Khorsabad) flourished as royal residences, but since only Ashur and Dur-Sharrukin have been at all fully excavated, we shall confine our remarks to the palace of Sargon II (722–705 B.C.) in Dur-Sharrukin.

The palace area occupies about 7½ ac., of which two-thirds are given over to the palace proper and the temple, the remainder being occupied by a large ziggurat probably composed of seven stages with an external spiral ramp. Basically, this plan is an elaboration of the traditional units that occur at Tell Asmar: square court, throne room, great hall. Each side of the court measures 300 ft., and its walls were revetted with monumental reliefs. In addition, great stone sculptures of monsters and genii, such as those that flanked the doorways, must also be considered as part of the architecture.

The final rebuilding of Babylon by Nebuchadrezzar II (605–562 B.C.) marks one of the greatest building achievements ever attempted by man. Excavations during the first decades of this century by R. Koldewey and the German Orient society revealed no less than four gigantic castles on this site. It was during the reign of Nebuchadrezzar II that the fabled "hanging gardens" were built. The Ishtar gate of Nebuchadrezzar's palace, decorated with lively bulls and dragons executed in molded and glazed brick, has survived well and ranks as the finest monument of this great period. Of the ziggurat of Babylon, the biblical Tower of Babel, little remains today other than the ground plan and a description of the Greek traveler and historian, Herodotus.

MINOAN CRETE

The great maritime civilization of Crete (*q.v.*) crystallized around the palaces such as exist at Knossos, Phaistos, Hagia Triada, Mallia and Tylissos. The immensely important "Palace of Minos" at Knossos, excavated and reconstructed early in the 20th century by Sir Arthur Evans, offers evidence of unbroken architectural and artistic development from Neolithic beginnings, culminating in a brilliant display of building activity during Middle Minoan III (1700–1580 B.C.), and continuing until the invasion of the Achaeans in the 12th century. However, the palace is essentially a structure of the last two Middle Minoan periods (1800–1580 B.C.). It no doubt rivaled near-eastern and Egyptian palaces in monumentality. As in these, a quadrangular complex of rooms and corridors is grouped around a great central court, at Knossos roughly 175 ft. × 100 ft. At the northern end, toward the sea, a grand portico of 12 pilasters gave access to the central court. At this end, also, is situated the grand theatrical area, a rectangular open-air theatre perhaps used for ritual performances. The east wing of the palace is divided into two parts by a long east-west corridor and rose four or five stories above the slope of the valley. The southeast portion of the palace contains domestic apartments elaborately supplied with plumbing and flushing facilities as well as a sanctuary. A wide stairway led to an upper story which no longer exists. The northeast portion of the palace is occupied by offices and storerooms. The west portion is again divided by a long corridor, over 200 ft. long, running north and south. Behind this corridor was discovered a series of long narrow storerooms containing great numbers of pithoi, or man-size storage vessels for oil. On the other side of the corridor, toward the central court, are the rooms of state, including the throne room with its unique gypsum throne and world-famous griffin frescoes.

Light was supplied from above by an ingenious system of "light wells," and several colonnaded porticoes provided ventilation during the hot Cretan summers. Brilliantly hued frescoes played an important part in both the interior and the exterior decoration of the palace.

The development of the other Minoan palaces (Phaistos, Mal-

lia, Hagia Triada, Tylissos) roughly parallels that of Knossos. Each has its special interest, and Phaistos is particularly fascinating, due to extensive Italian excavations. Maritime hegemony enabled the Cretan sea kings to build these palaces in low and unprotected places; consequently there is a conspicuous absence of fortification walls, as contrasted to the great walls of Mesopotamian palaces. Since Cretan worship seems to have been largely in the open air, there are no real temples as in the near east. Yet, the disposition of the various parts of the palace around the central court and the avoidance of outside windows as much as possible are characteristics that seem to indicate an early contact with the near east. A taste for long, straight palace corridors, as well as a highly developed water-supply system, may also have been inherited from older civilizations to the east. The column made its first European appearance in the Cretan palace, where it is often employed individually to divide an entrance way.

The development of funerary architecture in Crete proceeds from the old chamber ossuaries of the Early Minoan period (2750–2000 B.C.) to the developed tholoi or beehive tombs of the Mesara plain and the elaborate temple-tombs of Knossos at the end of the Middle Minoan period.

On the crest of Minoan prosperity came the great crash. An invasion from the mainland c. 1400 B.C. destroyed the palaces and resulted in the removal of power to Mycenaean Greece. Architectural remains in Crete which are pre-Greek and yet subsequent to this catastrophe are very rare. Several country shrines belong in this postdestruction period, and at Prinias a unique temple building may be as late as 700 B.C. The doorway of this temple is now in the Candia museum and has low reliefs on its architectural members. The opening above the lintel is flanked by seated figures, while the lintel itself is carved on its underside with figures of a goddess and of animals. That the Minoan tradition was not entirely extinct is indicated by the column which seems to have stood in the middle of this doorway, as at the "palace of Minos." (For a further discussion of Minoan palatial architecture, towns, sanctuaries and tombs, see CRETE: *Archaeology*.)

MYCENAEAN GREECE

The sudden architectural awakening of the Mycenaean Greek mainland is intimately connected with the zenith and decline of Minoan Crete and can only be understood against the background of a long Cretan development. Unlike Minoan Knossos, the archaeological remains on the mainland are fragmentary. In order to obtain an idea of Mycenaean architecture, we must draw on our knowledge of at least three sites: Mycenae, Tiryns and Pylos. Since the important architectural monuments visible today date largely from Late Helladic times (1580–c. 1100 B.C.) and since little earlier architecture is preserved, our brief survey shall be confined to this period. (See also *AEGEAN CIVILIZATION*.)

Fortification.—The tremendous building activity of the 14th century B.C. reflects an age of warfare, when powerful Greek-speaking kings built fortresses in key defensive positions on the mainland. The cyclopean walls of Mycenae and Tiryns (*i.e.*, the walls in which great blocks of untrimmed stone were employed) and the strategically placed Lion gate at Mycenae were constructed in this period. The latter consists of two colossal door jambs that support a monolithic lintel. The wall above the gate is so constructed as to form a relieving triangle over the lintel, and this empty space is blocked with the famous relief panel of two heraldising lions, which has given the gate its name. This method of construction provides an ingenious substitute for the arch which was unknown to the Mycenaeans.

Also justly famed are the concealed galleries of Tiryns, where the primitive corbeled vault makes its first appearance in mainland Europe.

Palaces.—Mycenaean palaces have been unearthed at Mycenae, Tiryns, Pylos, Gla and Phylakopi (Cyclades). The palace at Pylos is a typical mainland palace of the Heroic Age as described in the poetry of Homer. The characteristic plan comprises four elements: (1) a narrow court on which the structure fronts; (2) a double-columned entrance portico; (3) a vestibule (*prodomos*) and (4) the richly frescoed *domos*, or hall proper. The latter has

ARCHITECTURE OF MINOAN CRETE, MYCENAEAN GREECE AND ACHAEMENID PERSIA

a fixed throne at one end and a central fixed hearth between four wooden columns that supported an open towerlike structure rising above the roof for light and ventilation. Archives, comparable to those of the Hittite kings at Bogazkoy, were associated with this palace. Private houses, such as have been discovered at Mycenae, exhibit similar features as well as the basement storage magazines mentioned by Homer.

Tombs.—The earliest royal burials known from Mycenae are those of the two grave circles, the first discovered by H. Schliemann in 1878 and the second by A. J. B. Wace in 1951. These grave circles have no architectural character, consisting essentially of vertical shafts cut into the bedrock.

More important architecturally are the tholoi or beehive tombs. The evolution of these family sepulchres began in Minoan Crete, but culminated in the so-called "treasury of Atreus" at Mycenae, now believed to have been constructed as late as c. 1250 B.C. This most impressive monument of the Mycenaean world is a pointed dome built up of overhanging (*i.e.*, corbeled) blocks of conglomerate masonry cut and polished to give the impression of a true vault. The diameter of this tomb is almost 50 ft.; its height is slightly less. The enormous monolithic lintel of the doorway weighs 120 tons and is 29½ ft. long, 16½ ft. deep and 3 ft. high. It is surmounted by a relieving triangle similar to that over the Lion gate and decorated with relief plaques in a manner not yet established with certainty. A small side chamber hewn out of the living rock contained the burials, whereas the main chamber was probably reserved for ritual use. Two engaged half-columns of Cretan type (now in the British museum) were secured to the façade which was approached by a dromos, or ceremonial passageway, revetted with cyclopean blocks of masonry and open to the sky. Other tholoi, though not as excellently preserved, exist at Mycenae and Orchomenos.

TROY

Excavations at Troy (mod. Hissarlik, on the eastern shore of the Dardanelles) have distinguished no less than nine stratified levels extending from prehistoric into Roman times.

Houses at Troy I (c. 3200–2600 B.C.) and Troy II (c. 2600–2300 B.C.) were formed of long narrow groups of rooms that already seem to bear a relationship to the rectangular megaron, or large hall, of the Mycenaean dwelling, sharing, as they do, the fixed hearth, deep vestibule and most of the other architectural features of megara on the Mycenaean mainland. Defensive gates flanked by towers at Troy II recall the military architecture of Hittite Anatolia to the east.

Troy VI (c. 1900–1300 B.C.), the immediate predecessor of Homer's Troy, was largely demolished by leveling operations in Roman times and at the end of the 19th century by Schliemann. This city possessed a symmetrical layout, impressive walls and, like Troy II, gate towers of splendid masonry that could be the prototype of Mycenaean as well as classical Greek propylaea. A large megaron of Troy VI incorporates a row of three columns along a central axis in its plan, again anticipating a development of Greek architecture (*e.g.*, the first temple of Hera at Samos).

Another feature of interest at Troy is the un-Mycenaean use of sun-baked brick for walling, probably a link with the construction techniques of Mesopotamia.

As more becomes known about the peculiar un-Minoan Bronze-Age civilization of Troy, other parallels with the architectural evolution of pre-Hellenic and Hellenic Greece will no doubt emerge. It is not unlikely that Troy will eventually take its place as an important intermediary for the transmission of ideas from the ancient near east to the younger cultures of the west. (See also TROY.)

HITTITE ANATOLIA

Because of recent excavations at Bogazkoy, Alaca Huyuk and Kultepe in Turkey, it is now possible to talk with a good deal of certainty about Hittite architecture. These three cities possess the earliest remnants of Hittite civilization. Their architecture is of a rude and primitive kind, yet not uninfluenced by the more developed architecture of older civilizations in Syria and Mesopotamia.

Stones of colossal dimensions were employed in corbeled vaults for the construction of tunnels, gates and tombs. Monolithic orthostates, often decorated with reliefs, are common. At Bogazkoy (anc. Hattusas or Khattushash), the capital and most important city of the Hittites, as well as at other Hittite sites, such carved orthostates form the lowest masonry courses of palaces and temples. The absence of the column, employed by all neighbouring cultures, is conspicuous in Hittite architecture, square pillars serving in their stead. Also noticeable in the architecture of the Hittites is an apparent lack of axial planning. Hittite temples and palaces are built on an agglomerate principle, with rooms of varying dimensions grouped in tiers around a rectangular court. Internal communication must have been difficult.

Few buildings of architectural distinction remain from the Early Hittite period (1650–1460 B.C.), although from this period are the beginnings of monumental architecture on the Anatolian plateau. The flowering of Hittite architecture takes place during the three centuries of imperial expansion (1460–1190 B.C.), when the might of the Hittite kings was felt as far abroad as Egypt.

From this period date the great Hittite temples. Five such temples have been uncovered at Bogazkoy. In each of these, many small rooms are disposed about a large central courtyard. It was in this courtyard that the worshipers assembled. The cult statue was hidden in a remote holy of holies and seems to have been accessible only to the priesthood. In Temple I at Bogazkoy, this holy of holies projects from the core of the temple building, apparently in order that the cult statue could be illuminated by side windows. Numerous subsidiary rooms seem to have served administrative and storage purposes.

Architecturally, the palaces are closely related to the temples. As in the temples, the rooms of the palaces were grouped around a central courtyard. In contrast to the tightly organized palace-complexes of Crete and Mesopotamia, the palace of the Hittite kings at Bogazkoy consists of a number of isolated structures loosely disposed in a semicircular formation. Most of these buildings were multistoried, and, in addition to the royal habitation, an archive and a palace shrine have been identified. Two other excavated Hittite palaces of this period, at Kultepe and Huyuk, do not seem to differ substantially from that at Bogazkoy. The collapse of the Hittite empire at about 1200 B.C. is marked by destruction levels at these three sites. Subsequently, a short afterblossoming of Hittite culture took place in northern Syria at several centres where displaced Hittites, Aramaeans and nomads reassembled; and considerable architectural remains of this period have been uncovered at Carchemish, Tell Halaf and Zincirli in the foothills of the Taurus.

The employment of carved orthostates to adorn the lower part of a wall is a characteristic feature that unifies the architecture of these scattered sub-Hittite principalities and relates it to that of the Hittite empire at the height of its expansion. Another feature of the conglomerate architectural style that distinguishes these petty autocracies seems to be of Syrian, rather than Hittite, origin. This is the *bit hilani*, or pillared porch, the supports of which often rested on animal bases. (See also HITTITES.)

ACHAEMENID PERSIA

The origins of the monumental architectural style that appeared in Persia with the foundation of the Achaemenid empire in 539 B.C. are disputed. (See IRAN: *Archaeology: Achaemenid Period.*) It has been suggested that the Persians learned the art of cyclopean building from the Urartaeans of Lake Van to the north; other elements of Persian architecture are often traced to Mesopotamia and even Egypt. It is known for certain that Greeks were among the foreign craftsmen employed in the construction of the great Achaemenid residences. The presence of horizontally fluted column bases in the Achaemenid palace at Pasargadae, similar to those of the Archaic Greek temples at Samos, Ephesus and Naukratis, is only one of several examples of their influence.

Yet, notwithstanding the presence of such foreign elements, it cannot be denied that the architecture of Achaemenid Persia is remarkably original. Veritable forests of columns and square halls of vast proportions radically differentiate Achaemenid buildings

from the contemporary architecture in Greece and are more reminiscent of the native Persian development in Islamic times.

A great columned hall exists already in the palace of Cyrus at Pasargadae, the earliest of the three Achaemenid dynastic residences (other two: Persepolis and Susa). This palace was elevated on a series of man-made platforms and approached by a system of impressive stairways. A colonnaded gatehouse fronted by Assyrianizing bull-monsters gave access to the parklike enclosure in which stood the numerous pavilions and subsidiary buildings that comprised the palace. Among these there was the audience hall surrounded by four porticoes, each with a double row of pillars. Another building, believed to be the palace proper, has double porticoes flanking an almost square hall containing 30 columns arranged in 5 rows of 6 columns each distributed over the entire space.

The best-known, best-preserved and most spectacular of the Persian palaces is that at Persepolis (c. 521–388 B.C.). This enormous complex of buildings, terraces and stair ramps consisted, among other elements, of the palace of Darius I (522–486 B.C.), Xerxes I (486–465 B.C.) and Artaxerxes III (359–338 B.C.), a harem, a treasury, the Gate of Xerxes, the Hall of the Hundred Columns and a number of other buildings.

The Hall of the Hundred Columns at Persepolis is 225 ft. square, though its columns are only 37 ft. high as compared to 67 ft. in the smaller Hall of Xerxes at the same site. The gateways of the Hall of Xerxes are flanked by colossal winged genii similar to those associated with Assyrian palaces; flanking the stairway leading to the Audience Hall of Darius were discovered the famous reliefs of tribute bearers that have since found their way into museums throughout the world. Everywhere, sculpture was combined with architecture to produce a total effect of grandeur hardly surpassed by the great architectural complexes of Egypt.

At Susa, the palace is in part similar to that at Persepolis, in part related to the palace of Nebuchadrezzar at Babylon. The widespread use of glazed coloured bricks in the architecture of Susa also associates this palace with the earlier architecture of nearby Mesopotamia.

The aniconic religion of the Persians required only simple open-air fire altars for the perpetration of its rites. Consequently, there is no temple architecture, and only tombs remain to be mentioned. At Pasargadae, an early Achaemenid tomb, probably correctly identified as that of King Cyrus, consists of a rectangular single-roomed sarcophagus chamber with a gable roof recalling the tombs of Caria and Lycia in southwestern Turkey. The entire structure and the pedestal of six steps on which it stands are built of great blocks of well-dressed masonry and were formerly surrounded by a colonnade. Later Persian monarchs were interred in the cliff-hewn tombs at Naksh-e Rostam near Persepolis. PREHNITE, a relatively uncommon calcium and aluminum hydrous silicate mineral, is generally light green in colour and occurs in rounded masses of crystals. The individual crystals are not usually distinct to the unaided eye. Prehnite resembles cer-

tain varieties of the hydrous zinc silicate hemimorphite (q.v.). It can be distinguished from that mineral most readily by its lower specific gravity and by its type of geologic occurrence and associated minerals.

Prehnite occurs most commonly as crystal masses lining cavities in mafic (basic) igneous rocks such as basalt and diabase. Characteristically associated with it are calcite, quartz, zeolites, datolite and pectolite. Some notable localities of this type of occurrence in the United States are Paterson and Bergen Hill, N.J., Farmington, Conn., Westfield, Mass., and the Lake Superior copper district. It has been found at Cradock, Cape Province, S.Af., in the south of Scotland, the French and Tirolean Alps, the Hartz mountains and other localities. Prehnite also occurs less commonly and less strikingly in other types of rocks, such as schists, amphibolites and metamorphosed sedimentary carbonate rocks. The composition of prehnite is expressed by $\text{Ca}_2\text{Al}_2\text{Si}_3\text{O}_{10}(\text{OH})_2$. Small amounts of ferric iron (Fe^{3+}) may be present in place of some of the aluminum. (D. M. H.)

PRELATE, an ecclesiastical dignitary of high rank. In the early Middle Ages and even as late as the 14th century the title prelate was applied to secular persons in high positions. From this usage it passed to persons having ecclesiastical authority.

In the modern practice of the Roman Catholic Church, prelates, properly so-called, are those who have jurisdiction in the external forum; i.e., those who exercise the public power of the church. This true prelacy is defined as "preeminence with jurisdiction," and true or real prelates are distinguished as: (1) greater prelates, possessing episcopal jurisdiction, e.g., patriarchs, archbishops and bishops; and (2) lesser prelates, possessing a quasi-episcopal or other jurisdiction, e.g., abbots and prelates "of no diocese" and religious superiors, withdrawn from the ordinary diocesan jurisdiction.

The title of prelate has also been extended to ecclesiastical persons having a prominent office or marked by some special honour. Such titular prelates may be either active (high officials of the Roman court) or honorary. The honorary Roman prelacy is conferred upon ecclesiastics in various parts of the world as a sign of papal favour. Titular prelates, like true prelates, have their various ranks, differing as regards title, precedence, clothing, and other insignia.

In some of the Protestant churches the title of prelate was retained after the Reformation. In the Church of England it is restricted to bishops.

PREMATURE BIRTH is defined by the World Health organization as the birth of an infant weighing 5½ lb. (2,500 g.) or less. Another and preferable standard, birth at less than 37 weeks after conception, requires facts often unobtainable. Prematurity (by the standard of weight) occurs in about 7%–9% of pregnancies in white women in the United States, and in 10%–12% of those in Negro women; the rate in the latter is higher probably because of poorer socioeconomic conditions. In the U.S. prematurity is directly or indirectly responsible for at least 50% of all deaths of newborn infants.

A presumptive reason (usually multiple pregnancy, maternal toxemia or hypertension, abnormal attachment of the placenta or congenital malformation of the infant) can be found for 40%–60% of premature births, but fully half those of single infants are of unknown cause. Poor maternal health, hygiene and nutrition increase the likelihood of prematurity; maternal accidents and acute illnesses are insignificant as causes. The chief specific causes of death among premature infants are respiratory disturbances (hyaline membrane disease, atelectasis), infections (usually pneumonia) and hemorrhages, especially into the brain or lungs and often not caused by injury. With good care about 85% of all premature infants born alive should survive. In the large group born at 4½–5½ lb. (2,000–2,500 g.) 95% or more should survive; among the few born at less than 2½ lb. (1,000 g.) the survival rate may be less than 10%. An infant of 1½ lb.

(800 g.) rarely survives. In other words, chances of survival increase in direct proportion to weight.

Prevention of premature birth is not yet possible. Treatment of the infant begins with skilful obstetric management under minimal anesthesia during premature delivery, followed by specialized nursing and pediatric care in an environment approved as a premature infant nursery by public health authorities. This must provide the space, equipment and trained personnel for isolation against infection, regulation of temperature and humidity, feeding of human milk or special mixtures by tube or dropper and prompt relief of respiratory crises. Subsequently, instruction of the mother, supervision of home care and special attention to the nutritional requirements of rapid growth are needed.

Prematures weighing over four pounds (1,800 g.) at birth are usually born after 32 weeks, and they have much the same outlook for later growth and development as do term infants. Those of three pounds (1,350 g.) or less, especially if born before 28 weeks, are more liable to reduced stature and disturbed neuromuscular development. Research must therefore not only find means of preventing prematurity, or of increasing survival if prevention is impossible; it must also lead to normal growth and development after premature birth. See also FETAL DISORDERS; INCUBATOR; CHILDBIRTH.

See Herman N. Bundesen et al., *Progress in the Prevention of Needless Neonatal Deaths* (1951); Ethel C. Dunham, *Premature Infants: a Manual for Physicians*, 2nd ed. (1955). (C. A. SM.)

PREMCHAND (pseudonym of DHANPAT RĀY ŚRĪVĀSTAV) (1880-1936), Indian writer. Until about 1914 he wrote chiefly in Urdu, and thereafter usually in Hindi; his work consolidated the position of the novel and short story as Hindi literary genres (see HINDI LITERATURE; URDU LITERATURE). Born on July 31, 1880, at Lamahi, Premchand first worked as a teacher, becoming a sub-inspector of schools, but gave up teaching to join Gandhi's non-cooperation movement in 1921. He died on Oct. 8, 1936, at Banāras (Varanasi).

Much of Premchand's best work is to be found among his 250 or so short stories, collected in Hindi under the title *Mānasarovar* ("The Holy Lake"). Compact in form and style, they draw, like his novels, on a notably wide range of northern Indian life for their subject matter. Premchand's approach to his material is basically realistic, but a strong, conflicting vein of idealism also runs through most of his work. As a result, the novels particularly are of uneven literary merit, though not necessarily less valuable as a record of the life and mood of the northern India of the time. His 12th and last complete novel, *Godān* (1936; English translation 1956), is his best: in its main section he presents Indian village life and character vividly, refusing to sacrifice realistic detail to uncritical idealism; a less well-realized section, however, poses an artificial contrast between the values of village and urban life, and this mars the novel as a whole.

See English translation of part of *Godān* and a short story, "The Shroud," in *A Treasury of Modern Asian Short Stories*, ed. by D. L. Milton and W. Clifford (1961). (R. S. MCG.)

PREMIER: see PRIME MINISTER.

PREMONSTRATENSISANS (ORDO PRAEMONSTRATIENSIS, O. PRAEM.; or CANONICI REGULARIUM PRAEMONSTRATIENSIS, C.R.P.), called in America NORBERTINES, in England WHITE CANONS, a Roman Catholic order of canons regular, following the Rule of St. Augustine. The members are engaged in the solemn public enactment of the liturgy and in the apostolate of preaching, pastoral work and education.

The Premonstratensian order was founded in 1120 by St. Norbert, who, with 13 companions, established at Prémontré in Aisne a monastery that became the cradle of a new order. Though they followed the Rule of St. Augustine (see AUGUSTINE OF HIPPO, RULE OF ST.), their supplementary statutes made their life one of great austerity. St. Norbert was a friend of St. Bernard of Clairvaux and was much influenced by Cistercian ideals in both the manner of life and the government of his order. The order was approved in 1126 and quickly spread over western Europe. Later, after its austerity had been relaxed, reforms were undertaken and a number of more or less independent congregations

were created. The order was nearly destroyed by the French Revolution. Its modern centre of strength is in Belgium, where there are restored medieval Norbertine abbeys at Averbode and Tongerlo. Norbertine houses in the English-speaking world are located at Kilnacrott, Ire.; De Pere, Wis.; Storrington, Eng.; and Perth, Austr.

A second order of contemplative nuns and a third order of active sisters are affiliated with the canons. There are four provinces, called *circaries*; the world centre is the Norbertine generalate in Rome. The habit is all white. See also NORBERT, SAINT; ORDERS AND CONGREGATIONS, RELIGIOUS; MONASTICISM.

PREMYSL, the reputed ancestor of the Premyslid dynasty of princes and kings which ruled in Bohemia from 873 or earlier till 1306. According to legend Premysl, a plowman of Stadice, attracted the notice of Libuse, the traditional foundress of Prague, who played a part like that of the biblical Deborah as judge over the Czech people. Married to Libuse, Premysl is said to have become prince of the Bohemian Czechs in the 8th century A.D. The Premyslid Borivoj was prince of Bohemia in the last quarter of the 9th century, and his descendants in the male line ruled till the assassination of Vaclav (Wenceslas) III in 1306. It was through his marriage to Vaclav's sister Eliska (Elizabeth) that John of Luxembourg became king of Bohemia in 1310. For Premyslid rulers bearing the name Premysl Otakar see OTAKAR. See also BOHEMIA.

PRENATAL HEALTH: see MATERNAL AND CHILD HEALTH; PREGNANCY.

PRENDERGAST, MAURICE BRAZIL (1861-1924), U.S. painter, one of the first Americans to make intelligent use of the technical advances in Postimpressionism, was born in Roxbury, Mass., on Oct. 27, 1861. He began drawing in childhood and reached a painting career through executing show cards and carving picture frames. The latter craft maintained him and his brother Charles all their lives. During the 1880s Maurice spent two years studying art in Paris; on a second trip in 1898-99 he discovered the work of Paul Cézanne and painted watercolours in Venice. In his watercolours he developed a mosaiclike pattern of transparent touches which successfully conveyed the gaiety appropriate to their subjects of crowded parks and beaches. In his later oils, calligraphic drawing and opalescent colour in rich impasto drew a veil of wistfulness over similar scenes. His audience was never large, but with them his reputation was made secure by the works shown in the controversial Armory show in New York City (1913). He also exhibited with "the Eight," popularly called the Ashcan School (1908). The only important official honour he received was the third W. A. Clark Prize from the Corcoran Gallery, Washington, D.C., in December 1923. He died in New York City on Feb. 1, 1924.

See Margaret Breuning, *Maurice Prendergast* (1931). (VL. B.)

PREPARATORY SCHOOL, a term usually restricted to schools whose special task is to prepare students for entrance to another educational institution. In Europe, where publicly maintained secondary education is selective, preparatory schools are frequently private and often cater to pupils wishing to enter the academic secondary schools. In North America, where secondary education is less selective and entry to it less competitive, preparatory schools tend to prepare students for college; i.e., higher education (see COLLEGE).

In Britain the preparatory or "prep" schools form an integral part of the "public school" (i.e., independent school) system. Boys enter the preparatory schools at about the age of 8 and usually leave between the ages of 11 and 13, often to attend one of the some 200 institutions regarded as public schools. Before Thomas Arnold in the 1830s excluded boys under 12 from Rugby School there were few preparatory schools in England. By the middle of the 20th century over 500 preparatory schools were

members of the Incorporated Association of Preparatory Schools founded in 1892. Conditions of membership require that the headmaster or the assistant headmaster is academically well-qualified, that the school has more than 35 boys (all under 15 years of age), that it prepares them for public schools, and that it is recognized as being efficient by the ministry of education. Cooperation between the preparatory schools and the public schools is very close. A joint committee is responsible for the common entrance examination to the latter and papers are set in English, mathematics, Latin, Greek, and general subjects. The curriculum of many preparatory schools includes all these subjects, although Greek is no longer compulsory. Preparatory schools are found in many English-speaking parts of the Commonwealth of Nations and in Brazil and Peru. As high schools for girls developed in Great Britain preparatory schools for them were established with aims similar to those of the boys' preparatory schools.

In the United States, a very high proportion (over 90% in some cases) of preparatory school graduates enters college or university. The age of enrollment is about 15, and the four- or five-year course is usually geared to meet the requirements of either the college entrance examination board or a particular institution. The growth of the private or semi-public secondary schools in the United States is usually traced back to the suggestions made by Benjamin Franklin in 1743 in his *Proposals Relating to the Education of Youth in Pennsylvania*. His academy in Philadelphia, which later became the University of Pennsylvania, was the first of many. The period of greatest growth was the first half of the 19th century. Most of the academies were founded by religious bodies, were semi-public, provided a broader, more vocationally oriented curriculum than the Latin schools, and extended education to girls. After 1850 when the public high school movement gained momentum the number of academies gradually declined. Those surviving tended to become private independent schools, nonsectarian in outlook and concentrating on college entrance. In the second half of the 20th century about 1,800 institutions in the United States (of about 3,000 private schools) were listed as college preparatory schools. Admission tests usually include a general school ability test, largely in arithmetic, a reading test, and an English test. Co-operation between the schools and the private colleges has always been close. In 1885 the New England Association of Colleges and Preparatory Schools was formed to promote common interests. Later, other state and regional associations of this kind were established which have helped to standardize criteria for college entrance. There have been for many years student exchanges between certain of the U.S. college preparatory schools and certain English public schools.

Preparatory schools are found in many other countries. In Japan, after World War II, the number of upper secondary school graduates going to special private preparatory schools for a year or two prior to entering the university rose steadily. In Europe there has been a reduction in the number of private elementary preparatory schools or state schools for which fees are charged. In Sweden a few such schools remain in some large towns. The elementary private preparatory schools (*Vorschulen*) in Germany were abolished shortly after World War I by the Weimar Republic. In France, the preparatory classes (*classes préparatoires*), attached to the state *lycées*, were formerly fee paying. The differences between these and primary classes in other schools were abolished so that primary education became identical everywhere. See also EDUCATION, HISTORY OF; SECONDARY EDUCATION.

PRE-RAPHAELITE BROTHERHOOD, the name adopted in 1848 by a group of young English artists who reacted violently against contemporary academic painting and sought to set new standards in their own work. Although its active life

lasted at most ten years, the Brotherhood's influence on painting in England, and ultimately on the decorative arts and interior design, was profound. The members, all very young men, were seven, but in the initial stage they were only three, William Holman Hunt, John Everett (later Sir John Everett) Millais, and Dante Gabriel Rossetti (*q.v.*), all painters. The painter James Col-
linson, the painter and critic F. G. Stephens, the sculptor Thomas Woolner, and the critic W. M. Rossetti (*q.v.*; Dante Gabriel's brother) joined them by invitation.

Hunt, Millais, and Rossetti, students at the Royal Academy schools, were deeply dissatisfied with the anecdotal and unimaginative paintings which formed the bulk of the display at the academy's annual exhibitions, and determined to set a new example in their own work. Insisting that most contemporary painting was derivative and basically untrue to nature, they stated their aims as: (1) to have genuine and lively ideas to express; and (2) to paint always directly from nature and never at secondhand. They tried to look at things as if they had never seen them before and in their best work the vivid quality resulting from this keen sense of purpose survives with remarkable freshness.

The term Pre-Raphaelite occurred to them almost incidentally. They had none of them been to Italy and they could have seen in England very few Italian pictures painted before Raphael's time. They were, however, deeply impressed by a set of engravings from the frescoes in the Campo Santo at Pisa and they knew something through books and through their friendship with the painter Ford Madox Brown (*q.v.*) of the revival of the early Italian style in the work of a group of German painters, called the Nazarenes, especially that of Peter von Cornelius and Friedrich Overbeck (*q.v.*). "We had recognized," wrote Hunt, "that the Campo Santo designs were remarkable for incident derived from attentive observation of inexhaustible Nature." He also wrote that "the first principle of Pre-Raphaelitism was to eschew all that was conventional in contemporary art." They believed that the pursuit of the conventional, and its consequent departure from truth to Nature, resulted from the superlative academic example set by Raphael which had dominated teaching in the schools and

BY COURTESY OF THE TRUSTEES OF THE LADY LEVER ART GALLERY, PORT SUNLIGHT
"THE SCAPEGOAT" 1854, BY WILLIAM HOLMAN HUNT

academies of Europe ever since his time. Hence their decision to call themselves the Pre-Raphaelite Brotherhood (indicated by the monogram P.R.B.), and hence the gesture of defiance which the use of this monogram implied. For a short time in 1850 they published a journal, *The Germ* (edited by William Michael Rossetti), to which their friends Christina Rossetti and Coventry Patmore contributed, the theme of which was always "Truth to Nature."

The initiation of the Brotherhood was followed by the production of some of its most significant work, Rossetti's "Ecce Ancilla Domini" (1850, Tate Gallery, London); Millais' "Christ in the House of His Parents" (1850, Tate Gallery) which was savagely criticized by Dickens on the grounds of lack of reverence; and Hunt's "The Hireling Shepherd" (1851, Manchester Art Gallery). They frequently took their subjects from literature (e.g., Millais' well-known "Ophelia," 1852, Tate Gallery), and Rossetti had a

penchant for all things medieval, but perhaps their most representative work is that in which they were able to make a reference to the life of their own times and preach a sermon from it (Hunt, "The Awakening Conscience," 1854, in Sir Colin Anderson's collection; Millais, "The Blind Girl," 1856, Birmingham Art Gallery). Ford Madox Brown, although never a member of the Brotherhood, produced pictures of this kind which were wholly Pre-Raphaelite in style in "The Last of England" (1852-55, Birmingham) and "Work" (1852-65, Manchester); and a number of other young painters such as Arthur Hughes, Walter Deverell, and W. L. Windus also worked in the Pre-Raphaelite style. The work of the Brotherhood as a whole came in for severe criticism in its early days but it had a stout champion in John Ruskin (*q.v.*); and the members were never wholly without patrons, a number of whom were industrialists from the Midlands and north.

In 1858 Rossetti helped to organize a team of young men, Edward Burne-Jones and William Morris (*qq.v.*) among them, to paint a series of murals representing scenes from the Arthurian legend in the debating chamber of the Oxford Union. From this association developed what is now known as the aesthetic movement; but it is important to remember that Morris and Burne-Jones belonged to a new generation and that their work is totally un-Pre-Raphaelite in character. Indeed, after 1858, first Rossetti and then Millais gradually abandoned P.R.B. principles, and some of Millais' later great successes, such as "The North-West Passage" (1874, Tate Gallery) and "Cherry-Ripe" (1879, private collection), are the antithesis of all he was aiming at in the 1850s. Hunt alone pursued the same style fairly consistently. His masterpiece, and perhaps the masterpiece of the movement, is "The Scapegoat" (1854, Lady Lever Gallery, Port Sunlight).

PREROGATIVE, in English law, means the residue of discretionary powers and legal immunities that are left in the hands of the sovereign (throughout this article generally referred to as "the queen").

A distinction has to be made between two types of prerogatives: first, those peculiar to the queen in her "natural" capacity and confined to her, such as the rule that she is personally exempt from all jurisdiction and cannot be sued for debt; and, second, prerogatives that belong to her political capacity and as such extend to the whole government carried on in her name, such as the immunity of "the crown" at common law (before the Crown Proceedings Act, 1947) from being sued by ordinary civil process. English law, however, has never clearly distinguished between the two capacities, so that the sovereign has been completely identified with the state—indeed, modern British constitutional law does not employ the term "the state." All writs run in the queen's name, and "public" property is legally vested in the queen.

All statutory powers conferred upon the government as a whole, as distinct from a particular department, are declared to be conferred on "her majesty in council." All money voted by Parliament is voted to "the queen" even though it is appropriated by statute to public services from which she cannot divert it.

The prerogative powers of the sovereign, *i.e.*, power inherent in the kingship, as distinct from powers conferred on the sovereign by statute, can no longer be exercised by the sovereign in person but only on the advice of ministers or in particular forms and by the use of particular instruments. In foreign relations the queen has the exclusive power of making war and of declaring peace. The power is usually exercised by a proclamation and an order in council and, as such, it is binding on the courts. In practice the power is never exercised except with the approval of Parliament. The queen can make what treaties she pleases, provided they do not impose a tax on the subject or involve a change in municipal law. (Whether she can cede British territory by negotiation of such a treaty is more doubtful and has been much disputed.) Furthermore, it rests with the crown alone to "recognize" foreign governments as *de jure* governments. Such recognition is binding on the courts and, by a logical sequence, so is a declaration by the

crown that a particular person is entitled to the status of a foreign sovereign and as such is immune from the jurisdiction of the courts. So, too, with the status of an ambassador and the diplomatic immunity of himself and his suite. The queen is head of the naval and military forces of the country and can alone recruit them. However, the raising, recruiting, and discipline of the armed forces are regulated by statute.

The requirement that the queen assent to a bill passed by both houses of Parliament before it can be enacted may be regarded as an aspect of the royal prerogative in that the queen may, in law, withhold her assent. This prerogative is not dead but it has not been exercised since the reign of Queen Anne. In the case of colonies this prerogative still exists and may be exercised, for example, by a governor acting in the queen's name.

It is the sole prerogative of the queen to summon, prorogue, and dissolve Parliament. This is an executive, not a legislative, act and is performed only on the advice of ministers. It may be regarded as an accepted constitutional convention, at any rate since 1924, that the sovereign cannot refuse to dissolve Parliament when requested to do so by a prime minister. But the queen might still dissolve Parliament against the wishes of her prime minister under certain circumstances; *e.g.*, should a prime minister, having been defeated on a direct vote of confidence in the Commons, refuse either to resign or to ask for a dissolution.

The theory of the law is that the government of the country is still a matter of prerogative; although many, if not most, of the executive powers now exercised by the crown have been conferred upon it by statute—in particular the power of making statutory rules and orders to carry a statute into effect. (*See STATUTE LAW: Delegated Legislation.*) All ministers are appointed by the queen—on the nomination of the prime minister—and "kiss hands," or, as in the case of secretaries of state, receive their seals from the queen herself.

In the choice of a prime minister the queen has, both in law and in fact, a discretion; and she may send for whom she will, when the outgoing prime minister has resigned: this was shown by the selection of Harold Macmillan to succeed Sir Anthony Eden in 1957. All military and naval officers and governors of colonies are appointed by a "commission" from the queen. And as she appoints, so she dismisses every office under the crown, except that those of the judges and the comptroller and auditor general are held "during pleasure." English law imports into every agreement for service with the crown the provision that the servant holds his employment "at the pleasure of the crown." No servant of the crown has, apart from statute, any legally enforceable right to pay, pension, or security of tenure.

The queen is the supreme landowner, a relic of feudal doctrines, which means that, in the case of a man dying intestate and without next of kin, his estate goes to the crown. The queen also is the depositary of the prerogative of mercy: she can pardon those who offend against her "peace." This prerogative is now exercised exclusively on the advice of the home secretary. She is the sole grantor of titles such as peerages, baronetcies, and knighthoods, but "honours" are rarely conferred by her except on the advice of ministers. She is the "supreme governor" of the Church of England in virtue of the Acts of Supremacy and Uniformity.

In the course of English history, Parliament frequently has intervened to abolish some particular prerogative, and since the Revolution of 1689 it has never been doubted that such a statute binds not only the monarch who actually assents to it but all his successors as well. It was for long a matter of considerable doubt and speculation whether a statute could curtail a prerogative in the absence of express words to that effect; but it was decided in the case of *Attorney-General v. De Keyser's Hotel* (1920) that when Parliament has by statute regulated "the whole field of the prerogative," then that particular prerogative can be exercised in no other way than that prescribed by the statute.

PREROGATIVE COURTS, the name given by modern historians to the English courts much used under the Tudors and early Stuarts. The best known of these courts was that of Star Chamber, which, with the Court of Requests (*qq.v.*), had grown up during the later Middle Ages as committees of the king's council. Other "prerogative" courts, the Council of Wales, the Council of the North, the High Court of Delegates, and the Court of High Commission (*q.v.*), were set up by royal commission in the 16th century. By 1689 all these courts had been abolished or had fallen into disuse. Litigation in these courts was initiated by bill or petition, and crown proceedings were begun on information or by citation.

The term prerogative court was also used to denote the English provincial courts of Canterbury and York which granted probates and administrations in cases where the deceased left *bona notabilia* (goods above the value of £5) in each of two or more dioceses. The jurisdiction of these courts was transferred to the Court of Probate in 1857, and in 1875 it was vested in the probate, divorce, and admiralty division of the High Court of Justice. In the U.S. state of New Jersey the court having jurisdiction over probate matters came to be known as the Prerogative Court.

PRESBYTER, the title borne from very early times by certain officers or ministers of the Christian Church intermediate between bishops and deacons. The word is the original form of priest. See MINISTRY; CHRISTIAN; EPISCOPACY; PRIESTHOOD; PRESBYTERIANISM.

PRESBYTERIANISM. The term Presbyterian distinguishes a group of Christian churches which took form during the British Reformation and which have since given rise to other churches bearing the same name in the Americas, Asia, and Africa. It is also the specific name of a form of church constitution or polity which claims its origin in the church during apostolic times and reformulation during the Swiss Reformation. Subsequently, this system was adopted, with variations, by many churches in other countries, some of which use the original name "Reformed Church," others the name "Presbyterian Church," and others other names. Generally speaking, the churches of British origin use some form of the name Presbyterian, while those of continental origin use some form of the name Reformed. This article is concerned with the former group; for the latter, see REFORMED CHURCHES.

The Protestant Reformation in all the churches that became Reformed and Presbyterian arose partly from local roots and partly from outside influences. None of these churches received the Reformation as a finished system of faith and order which they had only to accept and adopt. Rather, each, over a span of years, sought to reform its faith, order, and life in the light of its understanding of the failures of the past.

As the Protestant Reformation in general got under way, these churches at first saw no real differences between themselves and the Lutheran churches. In the early period the influence of Luther, Philipp Melancthon, and other "Lutherans" was often felt in these churches. However, after 1529-30 the churches of northern Germany and of the Scandinavian countries began drawing together as a distinct Lutheran group on the basis of one single uniform pattern of faith and order (see LUTHERANISM). The Reformed and Presbyterian churches continued as before to work out their reforms largely in terms of their local situations. Each of these churches drew up its own creeds, catechisms, orders of church government, and liturgies; and most of them made new translations or editions of the Bible adapted to the needs of their people. What bound these churches into a family, therefore, were certain general convictions regarding the Christian faith, the right ordering of the church, the service of God among men, and the conduct of the Christian life. It has become customary in many countries to call these churches Calvinistic, because of their debt to John Calvin (*q.v.*), the reformer of Geneva. But Calvin was the great expounder of what these churches already believed; he did not teach them things before unknown.

The term Presbyterian requires, therefore, discussion under

two aspects: the Presbyterian churches of Christendom and the Presbyterian system, or manner of thinking about Christianity—i.e., doctrines, polity, worship, etc.

HISTORY OF THE PRESBYTERIAN CHURCHES

ENGLAND

In the English-speaking world Presbyterian ways of thinking first emerged in England. Even so, as events fell out, Presbyterianism became in time almost synonymous with "Scottish" and "Scotch-Irish," and English Presbyterianism was to lose its great bid to control the English Church, even at one period coming close to extinction.

Reformation.—The Reformation was late in taking hold in England and Scotland. The church in England remained unchanged in the Roman faith and obedience till 1534, the year in which Henry VIII's breach with Rome was completed. Yet that year marked only a hesitant beginning of reformation in England, and it was not till 1558 that Protestantism became at all secure. During the years before 1534 reforming influences were felt from several sources, among them the Christian humanists, the Lutherans, and the reformers of north Switzerland—Huldreich Zwingli and John Oecolampadius—and Martin Bucer and others of Strasbourg. The earliest English reformers, William Tyndale, John Frith, George Roye, John Rogers, Robert Barnes, Miles Coverdale, and others, began largely under humanist (Erasmian) influences, then were deeply attracted to Luther's work. But by the time (1529) Luther and his followers broke with the reformers of Switzerland and southern Germany, only Barnes, and perhaps Rogers, continued a straight Lutheran line. Since the outlook of the Swiss and south German reformers was that which is designated as Reformed, or Presbyterian, the major continental influence upon the English Reformation as a whole after 1530 was to be Reformed-Presbyterian.

Henry VIII tried to hold the church in England to a royally dominated nonpapal Catholicism. Under his son Edward VI (1547-53) Protestantism had a brief period of successful development. The leaders of the church, Thomas Cranmer, Nicholas Ridley, Hugh Latimer, and others, held it to a middle position between Catholicism and Protestantism, to the discontent of many who wished a more decisively Protestant position. These persons were greatly encouraged when several of the leading Reformed theologians of south Germany and Switzerland were brought into England by Cranmer in 1549-50 (Bucer, Pietro Martire Vermigli, Paul Fagius, and others). Yet Edward VI died before any drastic change in a Reformed-Presbyterian direction had taken place.

Under Mary's reign (1553-58) Roman Catholicism was restored, and 800 of the younger Protestant leaders fled to the continent, where they came under strong Reformed influences. These influences, plus considerations of English policy, made some of the refugees more English than ever and more determined to pursue an "English" Reformation. Others saw in the continental churches which sheltered them that type of Reformed-Presbyterian doctrine, polity, and character which they had already come to accept intellectually but which they had not yet succeeded in instituting in England. These exiles became more convincingly Reformed-Presbyterian than ever.

Elizabeth I (1558-1603) restored Protestantism to England, but it was the Protestantism of the middle way, now proclaimed to be the English way. Few of the returning exiles had wished for quite as much of a compromise as Elizabeth and her counselors forced upon them, though gradually most of their leaders acquiesced, largely because of fear that the only possible alternatives were worse. Those who refused to accept these compromises as final, and who sought to secure further reforms, became known by the spite name Puritans. (See PURITANISM.) They lost their first encounter, the vestment controversy of the mid-16th century, a concerted attack on the external aspects of the Elizabethan settlement. Then came a frontal attack by a group of Puritans who came to be known as the Presbyterian party.

Thomas Cartwright led a powerful movement (1570-73) aimed at eliminating the entire episcopal system through which Elizabeth worked. He advocated a presbyterian system, modeled on the

system of Calvin, in which the people chose their own pastors and then elected lay elders to share with the pastor in governing the local church. Central authority was vested in representative bodies of ministers and laymen who were chosen by the churches themselves or by the lower judicatures.

This first Presbyterian attempt at reforming the church was defeated. However, it did set in motion endeavours which shortly resulted in the working out, by Cartwright and others, of a coherent and comprehensive understanding of Christianity which formed the basis for all subsequent forms of Presbyterianism.

Its underlying structure was that of covenant-contract, now in a much more fully worked out form, having its nearest likeness in the covenant system of the Rhineland-Netherlands reformers (see COVENANT THEOLOGY). Its church government theory was most nearly paralleled by Calvin's theory. Its austerity, its "blue laws," and its theocratic outlook have often been traced to Calvin, yet medieval England and medieval Geneva had known blue laws, and Calvin's own attitudes had come to him from Zürich via Strasbourg.

The Presbyterians were sabbatarian and antilurgical, as were the Rhineland-Netherlands reformers; Calvin was the reverse. The Puritan and Presbyterian "prophesyings" were borrowed from Zürich. On decisive doctrines such as faith, repentance, law and gospel, the church, the ministry, and the two sacraments the Presbyterians stood nearest to the Rhineland-Netherlands reformers, not to Calvin or Luther. Politically their closest continental counterparts were the Huguenots.

Episcopal-Puritan-Presbyterian-Independent. — Though none of the contending groups in England realized it, the entire nature of the struggle, as well as the whole character of the English Reformation, was changing. The events which followed the excommunication of Elizabeth by Pope Pius V in 1570 terminated any real Romanist-Protestant controversy within England. Moreover, the rise of another generation within the Protestant group brought new issues to the fore. Such men as John Whitgift and Richard Bancroft led the episcopal party into a defense of the Elizabethan settlement on the grounds of divine right and royal authority. The Puritan group developed new tensions and alignments. The presbyterians demanded parliamentary establishment of their system, for which divine right was asserted. The Independents (later Congregationalists) became divided between those who desired the establishment of their system and those who wished a wholly free church with no established church of any kind. Moreover, other issues, baptism, "inner light," the ministry, etc., divided this latter group of Independents.

Each of these contending parties and groups sought control of the church in order to preserve or institute its own ideals. Each sought for allies—religious, political, and economic. As the struggle went on into the reigns of James I and Charles I it became, more and more, a barren power conflict, and theological or religious issues became secondary. Yet great theological changes were occurring. Within the royal-episcopal party a form of Arminianism (q.v.) became entrenched. Among the Puritans federalism (the perfected covenant theology) gained complete control—only to see Puritanism break up into three wings: (1) a right wing (presbyterian) stressing the objective, given character of the biblical revelation; the fundamental, given character of the natural law; the due authority of representative governing bodies in church and state; etc.; (2) a left wing (Brownist-sectarian) stressing the guidance of conscience, individual freedom, and the tentative nature of all external order and authority; (3) a centre wing (Independent-congregational) stressing the same general outlook as

THE BETTMANN ARCHIVE, INC.

THOMAS CARTWRIGHT (c. 1535–1603). LEADER OF THE PURITAN MOVEMENT UNDER ELIZABETH I

the presbyterian wing but wishing to vest all authority in local groups rather than in a powerful central authority. As the problem of power, or authority, dominated the entire struggle, all factions tended to lose sight of other events that were taking place. Accordingly, when the English Civil War began (1642) most men were unprepared for what they found to be the actual state of affairs. (See CIVIL WAR, ENGLISH: *Background to the War*.)

Beginning with the "Root and Branch Petition" to Parliament (1640), events moved steadily toward control of England by the presbyterian-parliamentary party. Charles was driven to accept a bill removing bishops from all temporal offices, and depriving them of their powers of arrest and imprisonment. This move satisfied many. The presbyterian-parliamentary party drove on, however, for a complete victory. By several overzealous acts they alienated the moderate nobles and others who had not yet declared for the king. Moreover, the Scots became neutral. Meanwhile Parliament abolished prelacy in the church and began preparations to institute presbyterian forms. An Assembly of Divines was summoned to advise Parliament in religious matters. Two ministers from each county of England were appointed, plus 10 peers, and 20 commons. A majority were Puritans of the right wing, a few were royal-episcopalians but they took no part; five were Independents.

The excesses of the king in 1642–43 drove the Scots once more into an alliance with his enemies. The parliamentary party now signed (1643) the Solemn League and Covenant with the Scots, pledging the civil and religious unity of England, Scotland, and Ireland under a presbyterian-parliamentary system. The Parliament now ordered the Assembly of Divines to proceed, with the aid of six Scottish advisers, to the drafting of a completely new religious constitution for the three kingdoms.

The assembly (called the Westminster Assembly because its meetings were held in Westminster Abbey) then elaborated (1643–49) a Confession of Faith, a Larger and a Shorter Catechism (see WESTMINSTER CONFESSION; CATECHISM: *Presbyterian*), a Form of Government, and a Directory of Public Worship. These documents, the results of years of debate by many able scholars, put in classic form a consistent federalism. The Westminster Assembly was merely an advisory committee of the English Parliament, however, and its constitutional documents met an odd fate. The Scottish Church and the Scottish Parliament accepted them promptly. The English Parliament delayed accepting them because of the growing power of the Independents. The English Church never had an opportunity to consider them.

Even with the aid of the Scots the military fortunes of the parliamentary party were unfortunate. It became necessary, at length, to allow Oliver Cromwell to create the New Model Army, which, although it proved invincible against the king, also proved invincible as the Independent-left-wing Puritans' force against the right-wing presbyterian Puritans. The army, not Parliament, became supreme in England. Its political-religious program alienated the Scots and the right-wing Puritans. Some right-wing leaders began to have intelligence with the king, believing that a government of law and order, though despotic, was better than army rule by sectaries. Eventually, in 1648, Col. Thomas Pride's soldiers "purged" Parliament of all presbyterians (140) leaving about 60 Independent Puritans in the Commons. This "Rump Parliament" tried and executed Charles I, set up a military dictatorship under Cromwell, terminated the Presbyterian establishment, and granted freedom to all religious groups while giving special privileges to Congregationalism under a modified form of establishment.

As the meaning of the left-wing movement became clearer the right-wing Puritans revolted completely. Many protested the execution of the king and the establishment of the dictatorship. Opposition was hampered seriously, however, by the now evident inner weakness of the right-wing movement. The presbyterian-Puritans had lost their popular following. Despite the large place accorded to the laity in the general structure of the presbyterian system, circumstances had led to the formation of only a ministerial party and not to the formation of a Presbyterian Church. Fear of the Independents and reliance upon Parliament and upon

strong political figures had been disastrous. Few of the several thousand congregations held by the presbyterians ever had elders or any lay leadership. Moreover, the controversy with the episcopal party had come to involve almost exclusively issues of greatest moment only to the clergy. The right-wing Puritan-parliamentary party, accordingly, was without enough popular support to take any decisive action.

Restoration, Revolution, and After.—Hopeless chaos reigned after Cromwell's death. Gen. George Monck reassembled the Long Parliament, thus putting great powers in the hands of the presbyterian-parliamentary group formerly purged by Colonel Pride. They reestablished presbyterianism, although granting tolerance to other Protestant bodies. Something better than army rule, however, was needed. Hence, all the right-wing groups, parliamentary and presbyterian, royalist and episcopal, joined in restoring Charles II unconditionally. Charles quibbled briefly with the presbyterians, who were now in full control of the church with about 8,000 beneficed ministers and professors. These ministers offered to accept a modified form of episcopacy first elaborated by Archbishop James Ussher. Charles, realizing that his real supporters were the royalist-episcopal group, rejected this offer and demanded capitulation. About 6,000 ministers accepted reordination, unqualified oaths of obedience to bishops and king, abjuration of the Solemn League and Covenant. Two thousand were ejected, of whom approximately 1,500 were presbyterian and 500 Independent. Later, many of these (about 500) conformed to the episcopal terms.

The Revolution of 1688 brought to the throne a king genuinely friendly to presbyterianism. In view of the total situation, however, no more was gained by his accession than a measure of toleration for all Protestants. Under this toleration and its subsequent enlargements, a number (often given as high as 500) of Presbyterian congregations existed. In almost no recorded instances did any of these churches have elders or any lay leadership. Ministerial thought continued to develop along extremely autocratic and High Church lines. Such presbyteries as existed were almost exclusively ministerial. Since many of the stronger churches became endowed, actual control of them passed into the hands of the minister and a few trustees. Laymen lost all part in them. In the early part of the 18th century many of these ministers became Unitarians and numerous others conformed to the Anglican establishment. The greater number of those who cherished the older Puritan ideals became Independent-Congregationalist under the influence of the movement known as the United Brethren, organized under the Heads of Agreement of 1691. By the close of the 18th century English Presbyterianism had become virtually extinct.

Scots began coming into England in increasing numbers after the union of 1707. Many of these were Seceders, hence rigorous Presbyterians. Soon they had several congregations. In 1847 these, together with certain of the surviving English Presbyterian congregations and other Scottish groups, merged as the United Presbyterian Church. This body joined with the remaining English Presbyterians and most of the other Scots churches in England to form in 1876 the Presbyterian Church of England. It then had 259 congregations with about 50,000 members. A theological college was founded at London in 1844, which later was moved to Cambridge under the name of Westminster College. In the 1960s the Presbyterian Church of England had about 325 congregations and 71,000 members. See also ENGLISH HISTORY.

SCOTLAND

Although Presbyterianism as such took form in England, and there received its definitive theoretical delineation by the Westminster Assembly, it was in Scotland that Presbyterianism was to take its deepest roots. Moreover, although the Scottish Reformation was begun under essentially Genevan Calvinistic patterns, it adopted in time, and became the very incarnation of, the patterns of English Presbyterianism. It was able, however, to give to laymen a real place in the life of the church. Consequently in no country did Presbyterianism so deeply affect the national life as it did in Scotland. In many ways Scottish history provides the best

available illustration of Presbyterianism at work.

John Knox.—Scotland's first reforming martyr was Patrick Hamilton (1504–28), who had been influenced by personal contact

with Luther, Tyndale, and other reformers. George Wishart, burned in 1546, had traveled in England and Switzerland; his ideas were essentially Zwinglian. His assistant, John Knox (g.v.), was to become the real leader of the Reformation in Scotland. Before long Knox had to flee and found refuge in England. During the reign of Edward VI he was an active leader in the English Reformation. When Queen Mary restored Roman Catholicism, Knox fled to the continent with the English reformers and eventually became pastor of an English refugee church at Geneva. In 1555–56 he visited Scotland and preached vigorously in the interests of the Reforma-

tion. The next year, certain nobles, the "Lords of the Congregation," led the Scottish reforming group in signing the first great covenant binding themselves to support the Reformation. Knox returned permanently to Scotland in 1559. A year later the reforming group, through English pressure on the Scottish regent, gained its first great victory. The Scots Confession (*Confessio Scoticana*) of 1560 was drawn up and accepted by Parliament. A Book of Common Order (Knox's Liturgy; see COMMON ORDER, Book of), a Metrical Psalter and a Book of Discipline (The First Book of Discipline, 1561) were also drawn up by the reformers. Parliament did not ratify these, but the church was deeply influenced by a rather general acceptance of them.

These documents were all decisively Genevan in character. Knox, who had been deeply influenced by Calvin, was the leader in their framing. The Book of Discipline was an advance on Calvin's system in that it applied Genevan ideals on a national scale, following a lead given by the Huguenots. A General Assembly was instituted as the national meeting of representatives of the church. Here, in free debate, issues were to be determined by a body of ministers and laymen met under their own chairman and at their own call. Also a governing body, the Church Session, was instituted for each local church. This body consisted of elders elected by the people and had as its chairman the pastor of the church. The people themselves were given the right to elect their pastor, and this election, rather than ordination by other ministers, made a man a minister. Episcopacy was abolished, but several superintendents were named to itinerate in areas without ministers and to have some limited administrative duties. The

religious prerogatives and authority of bishops were not given to them, however, and they did not preside over the church courts.

The last four decades of the 16th century witnessed the defeat of the Reformed, or Presbyterian, Scottish Church in spite of several notable temporary victories. In 1581 the Presbyterians gained parliamentary sanction for their Second Book of Discipline and for the so-called Negative Confession of Faith, better known as the King's Confession. Moreover, regional church governing bodies, the presbyteries, began to be set up. Yet, the Parliament of 1584 placed bishops in control of most of the church and the more prominent Presbyterian leaders were forced to flee to England. In 1592 the Presbyterians were able to extort from the king sanction for a parliamentary law which has ever since been regarded as the Magna Carta of Scottish Presbyterianism. Five years later the king, working through bishops forced upon the church, gained almost complete control of the entire church, a control which lasted until the first of the Bishops' Wars in 1639.

After the Union.—James VI of Scotland became king of England also in 1603 and then set out to make the Scottish Church the principal instrument of his absolutism in Scotland. Between 1603 and 1612 he brought the church wholly under the power of his bishops. From 1612 until his death he was occupied in shaping the life and work of the church to serve his general policies. At his death Scotland was under an unqualified absolutism.

Charles I (reign 1625–49) continued the Tudor-Stuart policy of using the episcopacy as an instrument in the furtherance of royal absolutism, with Archbishop John Spottiswoode his chief agent in Scotland. When, however, Charles, Archbishop William Laud, and Spottiswoode attempted to force the last degree of submission upon the Scottish Church, namely "Laud's liturgy," popular resentment came to the aid of the church. In a wave of public feeling expressing opposition to the whole of Stuart absolutism, the covenant of 1557 was "renewed" by signatures of all classes all over Scotland. Spottiswoode and all but 4 of his 50 fellow bishops fled to England. In the two Bishops' Wars which followed the Scots demanded, basically, free parliaments and free general assemblies. Charles lost the wars and granted the demands. Parliament and the General Assembly abolished the entire episcopal regime and restored Presbyterianism as of its "Magna Carta" of 1592.

In 1643 the two parliaments signed the Solemn League and Covenant between England and Scotland. Upon this basis of a union of England, Scotland, and Ireland in state and church, the two Presbyterian-parliamentary groups worked together in opposing the episcopal-royalist absolutism. One aspect of this cooperation was the adoption by the Scottish Church of the religious constitution framed by the Westminster Assembly. Scottish Presbyterianism thus passed from a Genevan-Calvinistic pattern to a Puritan-federalist pattern. When the Independents gained control in England, purged the presbyterians and executed Charles I, many of the Scots objected and proclaimed Charles II. Cromwell defeated the Scots' armies and held the country under military occupation. During this occupation the church was not persecuted. It had, moreover, a great series of religious awakenings under Covenanter leadership. (See COVENANTERS.)

Charles II, at the Restoration, brought back the episcopacy as an instrument of royal absolutism into Scotland as well as into England. Under Archbishop James Sharp a veritable Inquisition reigned in Scotland, "the killing times," as the Covenanter movement was wiped out. When William and Mary came to the throne in 1689 Presbyterianism was restored finally by constitutional act. However, despite some opposition, most of the former episcopal clergy retained their pastorates.

Presbyterian Scotland.—After 1689 Scotland was unquestionably Presbyterian, but new problems arose. Within the established state church were now two parties—one a group of convinced Presbyterians who had only recently been terribly persecuted by king and bishop, the other a group who had served the persecutors and now served the current regime with no great concern for it or against it. The next generation saw the rise of a large group of essentially professional clergymen known as Moderates, whose deepest interests were in social life, in culture, and in their pre-

rogatives within a state establishment. An Evangelical group sought to promote the older Reformation ideals. In 1707 the Scottish and English parliaments were united. Five years later the Parliament restored patronage in Scotland. This meant that the local landowner had the right of nominating the minister for the congregation, and the people lost the right of electing their pastors. This system of patronage quickly brought the Church of Scotland under the control of the Moderate ministers and the wealthy landowners. As many protests were made against patronage, the Moderates claimed supreme powers for the General Assembly, which they controlled, and did not hesitate to resort to the use of military escorts and to the imprisonment of dissenting ministers to enforce their dictates.

By 1733 resistance to the Moderates and to patronage led to the deposition of four ministers. Led by Ebenezer Erskine they formed a secession church, the Associate Presbytery (the Seceders). This body "renewed" the Solemn League and Covenant in 1742 and 1744. Even so some members desired greater attachment to the old covenanting ideals and withdrew to form the Reformed Presbytery (1743). In 1811 this group became the Reformed Presbyterian Church (see CAMERONIANS). Within the Seceder group also the covenanting principle raised the problem of their relation to the state, which supported the church from which they had separated themselves. In 1747 they divided into two groups, known after 1788 as the General Associate Synod (Anti-burgher; i.e., against taking the burgher's oath in various cities) and the Associate Synod (Burgher; i.e., willing to take the oaths). By 1799 and 1805 the problem of the civil government's authority in religious matters broke both these bodies into Auld Licht ("old light") and New Licht sections.

Meanwhile patronage and the Moderate party caused further discontent. In 1761 Thomas Gillespie (deposed in 1752 for resistance to the General Assembly) founded the Presbytery of Relief, a tolerant, evangelical, non-Covenanter body designed to provide relief for ministers and congregations who wished to withdraw peacefully from the establishment. In 1773 it assumed the name of Relief Church of Scotland.

These new groups grew rapidly, and were greatly strengthened by the evangelical revivals, the Sunday School movement, and the new missionary spirit. In 1820 a United Secession Church was formed by certain segments of secession bodies, and in 1827 others formed the Associate Synod of Original Seceders. These unions involved Burghers, Anti-burghers, Auld Lichts and New.

From 1833 to 1843 a severe struggle took place within the Church of Scotland between the Moderates and the Evangelical group, now greatly strengthened by the revivals and the Sunday schools. Finally when the government in London supported on legal grounds the entire Moderate structure, the Disruption led by Thomas Chalmers (*q.v.*) took place. A Free Church of Scotland

was formed by 474 ministers and thousands of lay people, free of state control, free of patronage, and zealously evangelical. All but one of the Church of Scotland's missionaries, and most of its best scholars, joined the Free Church. Thereafter the Free Church led all Christian causes in Scotland.

The United Presbyterian Church was founded in 1847 by the union of the Relief Church with the United Secession Church. In 1852 about half of the Associate Synod of Original Seceders joined the Free Church of Scotland. The year 1876 witnessed the union of the majority of the Reformed Presbyterians with the Free Church. Union negotiations between the United Presbyterian Church and the Free

CHURCH OF SCOTLAND

Church raised many problems. A small group left the Free Church in protest against the union and formed the Free Presbyterian Church. Eventually, in 1900 the United Free Church of Scotland was formed by a merger of the Free Church and the United Presbyterians. A small group, the "Wee Frees," remained outside as the Free Church of Scotland. In many ways the United Free Church was the most vigorous religious body in Scotland.

Before long, attempts were made to unite the United Free Church and the old Church of Scotland. Patronage had been abolished in 1874, and the old Moderate party had given way to a better leadership in the Church of Scotland. The issue of an established state church proved insoluble, however, until after World War I. Both churches had drawn closer together in the meanwhile. In 1921 the state by law severed its old relation with the Church of Scotland, leaving it "the national church" but not the established state church. This allowed union negotiations to make progress, and in 1929 the two churches united under the original name of the Church of Scotland. A small group remained outside and continued the name United Free Church.

Vast changes, meanwhile, had greatly altered the total religious situation in Scotland. The Lowlands had become industrialized and had brought in large numbers of Irish workmen, most of whom were Roman Catholics. The Highlands were being depopulated by changing economic conditions. Presbyterianism as a whole enrolled only a fourth of the population of Scotland, and three-fifths of the Scots were nominally in no church. The Church of Scotland had lost heavily among the labouring classes and in the rural areas. Various movements were under way, each seeking in some measure to improve conditions: a High Church liturgical movement; a movement to bring together in the church the labouring classes and student groups (Iona group); and a movement for the recovery of a more adequate theology. The Church of Scotland continued to be active in missionary work and to take a leading part in the ecumenical movement among the Protestant churches throughout the world. A move to affiliate the Church of Scotland with the Church of England was defeated in 1959.

Five Presbyterian bodies remain in Scotland (figures are approximate, for the mid-1960s): (1) Church of Scotland, 1,300,000 members, 2,300 churches; (2) United Free Church, 25,000 and 100; (3) Free Church of Scotland, 5,500 and 160; (4) Reformed Presbyterian Church, 550 and 5; (5) Free Presbyterian Church, 800 members.

IRELAND AND WALES

Ireland.—Except for scattered Puritan groups, Irish Presbyterianism began with the Irish plantation of 1610. These Presbyterians were first in the established church under the tolerant Archbishop Ussher. Charles I and Archbishop Laud drove them out. During the English Civil War they suffered vicissitudes much like those of the Scottish Presbyterians. William III gained for them only partial toleration. Until 1869 their harsh lot led hundreds of thousands to migrate to North America.

Scottish controversies usually had their counterparts in Ulster. Seceders appeared in 1741 and organized in 1750; Reformed Presbyterians came in 1752 and organized in 1792. The Synod of Ulster was the main Presbyterian body, but it did not include the Presbyterians in Dublin and south and west Ireland, which formed the Synod of Munster. Severe doctrinal controversies occurred in the 18th and 19th centuries. Each time a Unitarian group left the church. Consequently Irish Presbyterianism became very conservative in theology. In 1840 the Secession Church and the Synod of Ulster merged as the Presbyterian Church in Ireland. The Synod of Munster joined them in 1854.

Two Presbyterian bodies remain in Ireland: (1) Presbyterian Church in Ireland, with (mid-1960s) about 135,000 members and 550 churches; (2) Reformed Presbyterian Church, with about 3,400 members.

Wales.—The Presbyterian Church of Wales, known also as the Calvinistic Methodist Church, grew out of the evangelical revival

CULVER PICTURES, INC.

HOWEL HARRIS (1714-73), OF THE WELSH CALVINISTIC METHODIST CHURCH

of the 18th century. Howel Harris and other friends of George Whitefield led the movement and gave to it the general society character of the Wesleyan societies but the doctrinal convictions of Calvinistic Puritanism. Its earliest organization outside the Church of England in Wales took place in 1811 on a Presbyterian form of polity. Two synods, or associations, were formed, one for South Wales and one for North Wales. Twelve years later a Calvinistic, Presbyterian creed was officially adopted. In 1864 a General Assembly was formed

to unite, but not to control, the two associations.

The church is distinctly Welsh in all ways. About one-fourth of the congregations use the English language in some measure. In the 1960s it had about 150,000 members in 1,400 churches. See CALVINISTIC METHODISM.

COMMONWEALTH OF NATIONS

Canada.—Presbyterianism first took real root in Canadian territory after the Treaty of Paris of 1763. Settlement of Scots in Nova Scotia brought many Presbyterians there. In 1817 the various elements united as the Synod of Nova Scotia in Connection with the Church of Scotland. Then, in 1835, the Synod of New Brunswick in Connection with the Church of Scotland was formed. These bodies were all at work in eastern Canada.

Farther to the west the Church of Scotland was also sending ministers and aid. Secession groups had already organized, in 1826, the United Presbytery of Canada. In 1831 the Synod of the Presbyterian Church of Canada in Connection with the Church of Scotland was organized. These two bodies united in 1840.

The Disruption of 1843 in the Church of Scotland caused parallel ruptures in all the Canadian Presbyterian churches. In 1845 there were seven separate bodies. Thirty years later, in 1875, all had reunited in the Presbyterian Church in Canada, with several colleges and a strong body of congregations and ministers. Their next task was set by Canada's westward expansion.

The 20th century brought new problems to Canada, theological as well as social and economic. Roman Catholicism was growing. The sparse population of the Canadian prairies put a severe drain on all Protestant home mission efforts. The changing scene in Canada had made Protestantism too exclusively urban. As early as 1890 projects for uniting Canadian Protestants had been broached rather widely. The Church of England in Canada quickly dropped out of these negotiations, but the two largest Protestant bodies, the Presbyterians and the Methodists, together with the much smaller Congregational Church, united as the United Church of Canada in 1925. A sizable minority of Presbyterians refused to enter the union and continued as the Presbyterian Church in Canada.

The United Church of Canada continued to maintain official connections with other Presbyterian and Reformed churches throughout the world. In government it is essentially Presbyterian, although in doctrine and other matters it allows great latitude at points of view traditionally non-Presbyterian, because of Methodist and Congregational constituencies.

The two churches are represented as follows: (1) United Church of Canada (mid-1960s), about 1,000,000 members, 2,700 churches; (2) Presbyterian Church of Canada, 192,000 members, churches. (See also UNITED CHURCH OF CANADA.)

Australia.—Australian Presbyterianism was essentially Scottish in origin and character. The first organized body was founded in 1826 by Church of Scotland ministers. During the stormy years following, the divisions of the homeland had their counterparts in Australia. Reunions of fragments formed the Presbyterian Church of New South Wales in 1865; the Presbyterian Church of Victoria in 1870; and smaller bodies in Queensland, Western Aus-

tralia, South Australia, and Tasmania. A federal union of most of these bodies was formed in 1886, and in 1901 all united in the Presbyterian Church of Australia. Considerable local autonomy was granted each of the regional bodies. From 1918 to 1923 strenuous efforts were made to achieve a union among Presbyterians, Methodists, and Congregationalists similar to that achieved in Canada, but without success. The Presbyterian Church of Australia has about 104,000 members.

New Zealand.—Presbyterianism in New Zealand arose in two distinct migrations. To the northern regions came Church of Scotland ministers as early as 1840. The first presbytery was founded at Auckland in 1856 and later grew into the Presbyterian Church of New Zealand. In the southern area Scottish Free churchmen founded a model religious colony at Dunedin in 1848 which grew first into the Presbytery of Otago (1854), then the Presbyterian Church of Otago and Southland. In 1901 these bodies united as the Presbyterian Church of New Zealand. It has about 75,000 members.

UNITED STATES

There are ten Presbyterian bodies in the United States. Six of these, embracing 88% of all U.S. Presbyterians, are parts of one mainstream which is essentially American in origin and character. The other four (12%) are bodies which have sought to continue in the American scene certain specifically Scottish movements. The United Presbyterian Church in the U.S.A., the largest single body, is a union (1958) of two bodies of different backgrounds, the Presbyterian Church in the U.S.A. and the United Presbyterian Church of North America. The united church in the 1960s had more than 3,000,000 members in nearly 10,000 churches. Since the backgrounds of the two merged bodies are so different, an account will be given of each group prior to the merger.

The Presbyterian Church in the U.S.A.—The earliest Presbyterian churches in the American colonies were planted on Long Island by New England Puritans who preferred the presbyterian way to the congregationalist. Very soon after, Scotch-Irish, English, and other settlers formed Presbyterian churches in Maryland, Delaware, and Pennsylvania. In 1706, some of these joined in a loosely organized presbytery which in 1716 was expanded to a synod of three presbyteries. The church continued to be a blend of New England Puritan Presbyterians and Ulster Presbyterians, plus Welsh and other elements.

Because this new body was not attached to a parent body in Great Britain, it had to form its own character and constitution. The Scotch-Irish element regarded doctrine as the basis of the church, strove for unqualified subscription to the Westminster Confession and for centralized church authority able to enforce conformity. The New England element regarded the Christian life as the basis of the church, accepted creeds as expressions of the faith held by the church, and wished the superior church courts to have only limited and fixed powers. The revivals of the Great Awakening broke the church in two in 1741. The New England (pro-revival) element, called the New Side, trebled in the next few years, and the Scotch-Irish (anti-revival), called the Old Side, declined. In 1758 the two groups reunited on a compromise. At that time the New England element greatly outnumbered the Scotch-Irish. Beginning in 1760, however, several hundred thousand Scotch-Irish immigrants came to the colonies. Many of these joined the Presbyterian Church, and its character gradually changed to the Scotch-Irish pattern.

In the struggles leading up to the American Revolution the Presbyterians took a vigorous part. They formed an alliance with the Congregationalists of New England in order to prevent the settling of Anglican bishops on the colonies, because they feared an intolerant establishment was contemplated. The struggle for colonial independence was, in time, called a Christian cause. In personnel and property the church suffered heavily in the war. The near triumph of deism among Americans after the war came as a staggering blow to the church. During the years 1785–88 a General Assembly was founded with an explicit constitution. Some resistance was offered by those who feared extreme centralization. In the constitution, therefore, all reserve powers were left with the

presbyteries, and the higher, central, courts were given limited and fixed powers only. Doctrinal subscriptions continued to be flexible.

The church took up frontier missions, benevolent work, the founding of schools, etc., with vigour. A series of revivals greatly increased its strength, despite some concurrent problems. Charles G. Finney and Lyman Beecher were active evangelistic leaders of the second quarter of the 19th century.

In 1801 the church entered into a Plan of Union with the New England Congregationalists. Though the churches did not merge, they federated their home missionary work on the frontier. This drew the two denominations closer together everywhere, and raised again the old Scotch-Irish versus New England antipathies of the 18th century. Moreover, New England theology was restless and inquiring, while the Scotch-Irish tended to consider theology a finished structure which must be protected against innovation. In the South the church was almost wholly Scotch-Irish, and proslavery sentiment there kept most Northern Scotch-Irish Presbyterians either proslavery or neutral. The Presbyterians of New England background were generally antislavery.

After years of turmoil a majority in the assembly of 1837 abrogated the Plan of Union, expelled illegally all the federated churches, and demanded subjection by all to the assembly. During the ensuing year nearly half of the church refused to recognize these acts and joined the expelled group in declaring themselves to be the genuine Presbyterian Church and the group that had ousted them to be schismatic. The civil lower courts declared them to be the continuing church, but the appellate court reversed the decision. They continued the name Presbyterian Church in the U.S.A. and added "New School." The other group took the same name but added "Old School."

The New School denomination continued, as before 1837, to work in close cooperation with the Congregationalists in home and foreign missions, in antislavery, temperance, and other work. Though it had a few congregations in the South (these withdrew in 1856–57), it was largely a Northern church. The Congregationalists abrogated the Plan of Union in 1852, though the two churches continued some joint work. Even so, the abrogation was a setback for the Presbyterians. In frontier missions, education, and benevolent work they made great contributions. Union Theological Seminary in New York City became their great centre. During the American Civil War the church was active on the Northern side.

The Old School Presbyterians built a well-organized church on the basis of their doctrinal, racial, and social homogeneity. Though spread over all the nation, their great strength was among the Scotch-Irish and Scottish groups. Princeton Seminary became their focal point. A solid denominational structure enabled them to make great strides in missions, colleges, and Sunday School work. The Civil War brought new issues. The Old School Assembly of 1861 passed the Gardiner Spring resolutions which so wholly committed the church to the Northern view that the entire Southern section of the church seceded to form the Presbyterian Church in the Confederate States of America.

After the war the North-South groups of the two churches could not agree to reunite. Unions took place instead of New School and Old School to form in the South the Presbyterian Church in the United States (*see below*) and in the North the Presbyterian Church in the U.S.A.

The Northern reunited church took up frontier mission work anew, built new colleges and institutions, expanded Sunday School, youth, and benevolent work, as the nation moved westward. A quarter of a century of achievement was interrupted by a major controversy which arose as a result of the influence of the new scientific views upon Christian thought. There came first (about 1892) a long struggle over biblical criticism, followed (about 1910) by the organization, on an international scale, of an interdenominational group, strongly Presbyterian, to defend the "fundamentals" of the faith. By World War I the Fundamentalist-Modernist controversy was intense. Moderate groups pleaded for comprehension within the church of all essentially Christian views, but without success. The struggle now assumed a new form. The

Fundamentalist group attacked various boards and institutions of the church as unorthodox and founded within the church rival institutions of their own to compete with the church's institutions. This brought judicial process in the church courts against J. Gresham Machen and other Fundamentalist leaders. Most Fundamentalists then drew back from the controversy. A few, however, joined with Machen in founding the Presbyterian Church in America (see FUNDAMENTALISM).

Between World Wars I and II the Presbyterian Church in the U.S.A. came to have one of the largest foreign missionary enterprises in the world. In the U.S. the church sponsored more than 50 colleges and 9 theological schools. As national and international cooperative ventures among churches were launched the Presbyterians took an active part. Negotiations for union were undertaken with other Reformed and Presbyterian bodies and with the Methodists and the Episcopalians. The major part of the Cumberland Presbyterian Church (see below) reunited with the U.S.A. Presbyterians in 1906. The Welsh Calvinistic Methodists merged with the Presbyterians in 1920. Attempts to reunite the U.S. Presbyterians and the U.S.A. Presbyterians failed. In 1958 the United Presbyterian Church of North America merged with the U.S.A. Presbyterians. At the time of the merger the U.S.A. Presbyterians had 2,809,603 members and 8,658 churches.

United Presbyterian Church of North America.—Covenanters, or Reformed Presbyterians, began coming to North America, principally from Ireland, before 1750, and in 1774 their first presbytery was founded. Seceder Presbyterians organized a presbytery in 1758. Both groups were located principally in Pennsylvania. In 1782 the Reformed Presbyterians and some of the Associate (Seceder) Presbyterians united, and these together with other Secession groups united to form in 1858 the United Presbyterian Church of North America. Covenanter and Secession backgrounds made this church very conservative in doctrine and worship. At first it practised closed communion, sang only psalms in public worship, adhered to the Solemn League and Covenant, etc. Gradually, however, changes came as the memory of Scottish issues faded. The church was early active in the antislavery cause and in other significant reform movements. Due to its solid Scottish and Scotch-Irish background, its main strength lay in Pennsylvania, Ohio, New York, Illinois, and Iowa. When in 1958 the church merged with the U.S.A. Presbyterians it had 251,344 members and 833 churches.

The Presbyterian Church in the United States.—This body, commonly called the Southern Presbyterian Church, came into being during the Civil War, when the Old School churches in the Confederate states seceded from the Presbyterian Church in the U.S.A. to form the Presbyterian Church in the Confederate States of America. The war also cut off other Southern Presbyterian bodies from their Northern brethren. Older lines of cleavage lost their meaning. In 1864 the United Synod of the South (largely New School) merged with the Confederate Presbyterians, as also did certain small units of Seceders and Covenanters. Border state Presbyterian bodies, at first neutral, joined also: Synod of Kentucky, 1869; Synod of Missouri, 1874. After the war, the name Presbyterian Church in the United States was adopted.

The church continued to devote its energies to the Southern states, Texas, Arkansas, and Missouri marking in general its western boundaries. It is essentially Scottish and Scotch-Irish in membership and traditions. Its homogeneity ethnically, geographically, and socially makes it a very close-knit body. Traditionally the church divides between a spiritual and a political approach to problems, always rejecting the latter. As a result the church has been very conservative on all religious, political, and social issues. Yet in educational and benevolent enterprises it has long been a leader in the South, its educational and missionary ventures being especially significant. In its polity great care has been taken to promote local initiative and to restrict the powers of all central agencies.

The church in the mid-1960s had nearly 1,000,000 members in about 4,000 churches.

The Cumberland Presbyterian Church.—The Cumberland Church grew out of a purely American situation—frontier condi-

tions. Differences of opinion regarding the great Kentucky revival of 1799–1802; impatience with high educational requirements for a frontier ministry and with excessive ecclesiastical authority; differences on the subject of predestination, etc., brought about a separation, in 1810, from the Presbyterian Church in the U.S.A. of a group on the Kentucky-Tennessee frontier. The Cumberland Presbyterian Church they founded stressed evangelism, repudiated predestination, avoided highly centralized authority, etc. Early in the 20th century negotiations for reunion with the Presbyterian Church in the U.S.A. began, and a majority of the Cumberland Presbyterians rejoined the older church in 1906. Others, however, have continued as a distinct group under the Cumberland name, with about 90,000 members in 1,000 churches in the mid-1960s.

Until the Civil War, Negroes, lay and ministerial, had a very real place in the Cumberland Church. In 1869, however, they separated to form the Colored Cumberland Presbyterian Church. In 1940 this body was joined by a presbytery in Liberia. Later renamed the Cumberland Presbyterian Church in the U.S. and Africa, it has about 20,000 members in approximately 200 churches.

Churches Continuing the Covenanter-Secession Tradition.—There are four of these bodies (statistics are for the mid-1960s and are approximate):

1. The Associate Reformed Presbyterian Church (General Synod); 28,000 members, 150 congregations.
2. The Associate Presbyterian Church of North America; 500 members, 7 congregations.
3. The Reformed Presbyterian Church of North America (Old School); 6,000 members, 70 congregations.
4. The Reformed Presbyterian Church in North America (General Synod); 1,000 members, 10 congregations.

Bodies Formed Later.—The Fundamentalist-Modernist controversy of the 20th century led to the formation in 1936 of the Presbyterian Church in America (see above). Further doctrinal controversy broke this group into two distinct bodies a year later.

1. The Orthodox Presbyterian Church, a body stressing classical Presbyterian orthodoxy and extremely conservative in worship organization, and practice. In the 1960s it had about 10,000 members in 90 congregations.
2. The Bible Presbyterian Church, a body stressing revival evangelism and Bible institute work; it is more loosely organized than the parent body. Members numbered about 5,000 in 68 churches in the 1960s.

Presbyterian Bodies on Former Mission Fields.—Presbyterians have long been active in foreign missionary work. Especially in the years since World War II, the older European and American bodies have aided their mission-founded congregations in becoming self-governing indigenous churches, while continuing to provide them with money, personnel, and technical assistance. In Africa, Latin America, and Korea, most of these "younger churches" are Presbyterian bodies. In a number of countries of the Near East and Far East, the Presbyterians have merged with other Protestants to form united churches.

THE PRESBYTERIAN SYSTEM

The Presbyterian way of ordering the life of the church intends to be no more than a systematic and consistent attempt to follow the general principles laid out in the New Testament. It is confessed that the New Testament presents no one, definite, complete pattern. However, the very nature of what is there said of the gospel, the church, the ministry, etc., is taken by those who hold this system as an adequate indication of the basic elements essential to the ordering of the church's life. Not all who have called themselves Presbyterian or Reformed have ever followed Calvin in all things, but the system is best described by reference to his presentation of it.

The Church.—Calvin's view of the church was shaped by his understanding of the gospel. The gospel was the "good news" of God's forgiveness of man and the call to man to return, to be reconciled, to God; i.e., to repent. Forgiveness and reconciliation were inseparably bound together. Men were to be reconciled to God by receiving his forgiveness and to be reconciled to their fellow men by their mutual forgiveness. To be reconciled to God

was to come into his fellowship, and to be reconciled to one's fellows was to come once again into their fellowship. On that basis there could be no private or individualistic salvation. Salvation was intensely personal, because the Christian became a responsible actor, but never a matter involving only the individual soul and God. Calvin, therefore, was much opposed to mysticism and its view that each individual sought God alone and directly: "Outside the church there is no salvation."

This sense of community, or fellowship, in Calvin's opinion, was to be seen also in God's method of redeeming men. It was God who sought men rather than men who sought God. Yet God did not work directly but through agents, through means. God redeems men through the agency of their fellow men. God's love, which brought men to himself, was given to men through other men, thereby forming a bond of unity among them greater than any other conceivable bond. God was the source of all good, spiritual and temporal. But because he dispensed this good to men by the labours of others, each owed to the other that which he had received. Therefore, mutual sharing was necessary. This was part of reconciliation and love.

The church, then, according to Calvin had as its sole function the task of telling men of God's forgiveness and of leading them to reconciliation with God and their fellows. This involved several other things. Men could not accept forgiveness and agree to be reconciled to God and man without confessing that they were in need of doing so. Moreover, to be reconciled meant to be reconciled to the service of God among one's fellow men. The Christian life was to be lived among God's people for their good and God's glory, not for any selfish desire for temporal or eternal gains. Ethics, therefore, were always part of theology in Calvin's thinking. Political and moral problems dominated his activities. Though the economic application was stated in principle, it was never as fully worked out.

Since there is only one Christ, or head, Calvin declared, there can be only one church or body. Wherever Christ is present, redeeming men in a manner essentially agreeable to the pattern he himself laid down, there, men are to know, is the church. Wherever a religion contrary to Christ's own pattern was being offered to men, there, men were to know, was no church of Christ. This was the one basic difference between the papacy and the reformers. The unity, continuity, universality of the church were all to be found in the redeeming presence of Christ, not in any particular form of government, doctrine, leadership, or lineal descent. The church was the body of Christ on earth among men, and therefore plainly visible to all. Yet because it is all too human there are senses in which it is impossible for men to mark out its exact boundaries, etc. In that sense the church is invisible, and we are "to believe the church," he said; *i.e.*, we are to believe that this very imperfect community is truly the body of Christ.

The Ministry.—Two aspects of the nature of the church, Calvin said, provide the occasion or reason for the ministry, namely, that the church is a community and that its own life and felicity are not the reasons for its existence. It exists for the service of God. Consequently direction and leadership are needed, and this the government or ministry of the church is instituted to provide.

The one head of the church is Christ and no one is ever his substitute or vicar. However, Christ moves his people to elect from their membership various persons to discharge the various aspects of the church's function. Some are to preach, some to teach, some to care for the poor and sick, some to exercise discipline, etc. As Calvin believed, God himself called his ministers, but he did it through the church. The ministry does not exist parallel to or prior to the church. God, working through the people's election, calls the ministry. The ministry is not then a sacred or spiritual "order" of men. It is a group of officeholders within the body of Christ.

The church ordered its life in the service of God, then, in Calvin's thinking, by means of a ministry exercised by a variety of officeholders: pastors, teachers, elders, and two types of deacons. The pastors were to preach the gospel, to administer the sacraments, and to serve as presidents of the other officers. Because they had

the most responsible office within the total ministry, they might be called "the ministers." The teachers were to devote their whole time to teaching. Elders were to share with the pastors the spiritual oversight of the church. Deacons, men and women, were to care for the poor and the sick. No one was to exercise any function to which he had not been elected, and election to an office by the people was the sole necessary qualification. No matter to what office a man had been elected, he remained merely one of the brethren. Any distinction between clergy and laity was one of function alone.

God's call, made known through election by the people, was for Calvin all that was needed to make anyone the holder of any office in the ministry. Ordination by other ministers, he asserted, could not make anyone eligible to serve any office. When the ceremony of ordination was used, he declared that it meant no more than that the ministers led the people in a solemn prayer that God would recognize as his act that which they had done in electing the man in accord with what they believed was his will.

Those who hold offices in the ministry do so only within the church. They have no personal authority or virtue, Calvin said. Consequently, they may act only on the authority and prerogatives given them.

Government.—Though Calvin believed that the system of church government which was used by himself and his associates in Geneva, Strasbourg, Zürich, etc., was based upon the Bible and the experience of the church, he did not claim for it exclusive divine right. He acknowledged the English Church under Archbishop Thomas Cranmer and the Lutheran churches of Germany under their consistorial system as true and complete churches. Cranmer and the Lutherans also acknowledged the Reformed churches.

The primary elements of Calvin's theory of church government may be summed up in three. The church is a community or body in which Christ only is head and all other members are equal under him. The ministry is given to the whole church and is there distributed among many officers according as God has gifted and called them. All who hold office do so by election of the people whose representatives they are. The church is to be governed and directed by assemblies of officeholders, pastors, and elders, chosen to provide just representation for the church as a whole.

Since the Reformation the various Reformed churches have made many adaptations of this basic structure, but without departing from it in essentials. In the Presbyterian churches of British-American background, there are usually four categories of church courts, or judicatories, outlined below.

Session, Deacon, Trustees.—On the congregational level, there are the session, the deacons, and the trustees. The session is made up of the elders and the pastor, who is also the moderator, or chairman. To the session belongs the care of all religious, or strictly churchly, jurisdiction. It supervises the calling and election of pastors, receives and dismisses members, determines the order of the services, and exercises church discipline. The deacons, over whom the pastor is also the moderator, care for the poor and any other temporal affairs assigned to them. The trustees, under their own chairman, have charge of the property and fiscal and legal obligations of the congregation. All these officers are elected by the congregation. The elders and deacons are ordained to their offices by the pastor. Ordination is for life, but the exercise of the office is often for a term of years. The trustees serve for stated terms and are not ordained.

Presbytery.—All of the ministers, in pastorates or not, of a given area, together with certain elders deputed by the churches of that area, form a presbytery. In their hands rests authority for ordaining, installing, removing, or transferring ministers. Ordinarily the people may elect their own pastor, but the presbytery must sanction their choice and install him in office. Once installed, the pastor may not be dismissed by the people, or leave the people, without consent of the presbytery. The presbytery also has religious, financial, and legal authority over all the congregations. It serves as a court of appeal for cases coming up from the congregational courts. It meets as often as it wishes. The moderator is elected annually.

Synod.—The synod is made up of several presbyteries. It may be a delegated synod to which only a few representatives from each presbytery are sent, or it may be a synod to which all the members of all the presbyteries belong. In either case its jurisdiction in modern times is slight. It is a court of appeal in judicial matters, and it has a certain coordinating role in church program matters among the presbyteries. A synod usually meets only annually, and its moderator is elected annually.

General Assembly.—The General Assembly is an annual meeting of commissioners, ministers, and elders, elected by all the presbyteries (not by the synods) in number according to their total church memberships. This body elects its own officers, the moderator for one year only, the stated clerk for a longer term. It has charge of all the general concerns of the church's faith, order, property, missions, education, and the like. The missionary, benevolent, educational, and publishing work of the denomination are under boards elected by the assembly. The assembly also functions as the final court of appeal on all cases coming up from the lower courts.

In Presbyterian churches of British background the assembly is the seat of ultimate authority and the lower courts are regarded as descending from it. In churches of American background the presbytery is regarded as the basic unit. The synods and the assembly are regarded as formed by the presbyteries, and the congregations are considered dependent upon the presbytery.

WORSHIP

The Christian humanist movement prior to the Reformation had been highly anticlerical and bitterly opposed to the increasing elaboration of symbol and ceremonial in church worship. Even men such as Sir Thomas More, later a Roman Catholic martyr, and Erasmus had urged drastic simplification of the liturgy. Some even urged the removal of organs and choirs from the churches. Elaborate vestments also came under severe attack. Most Christian humanists agreed with Erasmus that a clergyman was essentially a teacher of Christ's philosophy of life.

In varying ways every Protestant reform movement incorporated some part of this older protest. The Reformed and Presbyterian churches attempted radical reform, although the pattern of action was not everywhere the same. Emphasis was put upon the congregational character of worship. The people all participated rather than acted as a mere audience. Symbolism had been intended to teach the unlearned. A better teaching ministry could now supersede the images, incense, gestures, and lights. Since all believers were alike in Christ, the clerical vestments which symbolized the religious distinction between clergy and laity were rejected. Only garb symbolic of offices and duties was to be used. Clerical choirs were to be supplanted by congregational singing. Luther had developed a Protestant popular hymnody welding folk tunes and evangelical texts. The Reformed churches used popular melodies but confined themselves to psalms and other biblical texts. In part this was a carry-over from the psalm singing of the anticlerical humanist circles of France from which many of the Calvinistic leaders came.

Liturgically, no Protestant group in the 16th century advocated wholly free worship. Since all were struggling to win people away from the Roman Mass, all believed that a proper and required form of service was necessary. All the Reformed and Presbyterian churches, therefore, began with some form of stated liturgy. The churches of northern Switzerland and Holland had perhaps the simplest forms. The churches of French-speaking Switzerland, the Huguenots and the earlier Scots and English Puritans followed a fuller form derived from Martin Bucer's service at Strasbourg and modified by Calvin. In this form the service opened with a salutation, followed by the common confession of sin, the words of assurance of pardon through faith, and a psalm of praise and thanksgiving. Then came the preaching and hearing of the Word of God which involved a prayer for the right understanding of the Word, the Scripture lesson, and the sermon based on that lesson. Attention then shifted to concern for others as the prayer of intercession for all sorts and conditions of men followed. Next came the Apostles' Creed as an expression

of oneness with all other Christians through the ages. The Lord's Prayer, again common to the universal church, a psalm, and the benediction closed the service. Probably the alms for the relief of the poor came after the creed. In later Scottish Presbyterianism the alms were often taken up as the congregation left the church to signify that they were given for fellowman rather than as a sacrifice to God, who needed nothing.

Perhaps the most striking feature of the service when it included the Lord's Supper was that the stress fell upon the redemptive work of Christ to which the sacrament testified rather than upon the sacrament itself. To that end there was no consecration of the elements nor any focus upon them. In Zürich and north Switzerland the ministers and elders brought the bread and wine to the people in the pews. In Holland and Scotland tables in the aisles, or even out-of-doors, enabled the congregation to "sit at the Lord's Table." In Geneva the people received the communion standing before the table. Pew communion is today regarded as the most meaningful way of expressing the congregational or community aspect of the Lord's Supper. See also *LITURGY: Protestant Liturgies*.

PRESBYTERIAN THOUGHT

In the early decades of the Protestant Reformation none of the major groups influenced by it thought of itself as a "denomination" with ideas which were "Lutheran," "Anglican," "Presbyterian," or "Reformed." Rather, each professed to be seeking to understand and to follow the one Christian faith. But just because their situations and circumstances were so different, these groups soon found themselves, though with large areas of agreement, also with stubborn spots of disagreement.

The Presbyterian and Reformed churches have characteristically maintained certain attitudes toward their differences with other Evangelical or Protestant churches. They have insisted that the Christian faith must be confessed in the specific and local circumstances and that only on the great essentials is complete uniformity required among churches. Therefore these churches have no one creed or liturgy or polity which unites them internationally as in Lutheranism or Anglicanism. In ecumenical relations they regard all other evangelical denominations as they do themselves namely as particular expressions of a common faith. They wish to practise intercommunion with other churches and to receive from or to transfer to them members and ministers on the basis of mutual recognition.

The Bible.—The Protestant Reformation was in part a consequence of the revitalization of biblical studies among the Christian humanists, who demanded that the church be reformed by a return to the teachings of Jesus, of the Bible, and of the early Church Fathers. Since many of the Protestant reformers had begun as humanists, they followed the same pattern of thinking. The Bible represented original Christianity. It was older and more universal than the papacy. The early Church Fathers understood Jesus and the Bible better than the medieval scholastics did.

Whereas the Christian humanists had understood the Bible primarily in terms of the ethic of the Christian life, the Protestant reformers read it primarily as the theological interpretation of God's redemptive work among men. Among the Reformed and Presbyterian leaders the entire Bible was read as the record of one history of redemption stretching over many centuries, culminating in Jesus Christ. While Christ was the key to understanding the Old Testament, it was necessary to retain the Old Testament in the Christian church in order to understand the history of God's dealings with men.

The Christian humanists had agitated for reform and had defined many areas of church and society that needed reform. But they had urged that action must come from the traditional authorities in church and state. The Protestant reformers, by forcing the issue of practical reform, inevitably raised the question of authority. Luther and many early Reformed thinkers such as Zwingli urged that the civil government must assume authority in both church and state. Other Reformed thinkers, especially the Huguenots, the Dutch Calvinists, the English Puritans, and the Scots Presbyterians, followed the lead of Calvin in

demanding that the church be allowed to retain many of its old institutions and prerogatives and be supported in their use by the state. This early form of separation of church and state in jurisdiction raised many serious problems. Since it went beyond previous European experience the question arose as to what patterns to use. The New Testament writers and the early Church Fathers had lived under persecution, hence they set no patterns for the new Protestant state churches to imitate. Those who followed Calvin's lead, therefore, sought these patterns in the Old Testament. Yet, the Genevan "theocracy" in its attempts to reform and control moral conduct was usually motivated by medieval attitudes toward the "flesh." Its novelty lay in its insistence upon one inflexible standard for clergy and laity alike.

The Old Testament had profound influence upon the political thought of these churches. The tendency to use it as a code book to which appeal could be made against traditional church or civil authority led directly to making the political theory of fundamental law, or constitutional law, a religious tenet. Law stood over the ruler. Likewise, the Old Testament idea of a covenant (*q.v.*) between God and his people which bound even the king and the high priest made the then obscure contract theory of political authority (*see* SOCIAL CONTRACT) a sacred cause among these churches. Since in the Old Testament wicked kings were repudiated, the growing assertion of the divine right of kings was rejected by the Reformed churches as non-Christian. Eventually most of them espoused the right of a people to rebel against an unjust ruler.

The fact that in the Old Testament God's redemptive work among the Israelites was presented as going on through many centuries, and reaching a climax in the historical work of Christ among men, aroused among some Reformed leaders (as Bullinger, Jud, and Pellicanus) the beginnings of an interpretation of history which was to culminate in the influential 19th- and 20th-century "history of salvation" (*Heilsgeschichte*) theory of biblical hermeneutics.

The Work of Christ.—All Protestant groups in the 16th century agreed that man's salvation was wholly the work of Jesus Christ and that it was in no way the result of, or dependent upon, human merit. Yet, the manner in which one understood the work of Christ had important bearings upon how one understood its consequences in the life of a Christian. Technically, the discussion of the work of Christ under the ancient categories of prophet, priest, and king, which Calvin popularized in all the Reformed and Presbyterian churches, need not have caused differences with the Lutherans. But the fact that Calvin insisted upon distinguishing what Jesus Christ did as man from what he did as God had far-reaching consequences. All agreed that Jesus in his human life revealed what man ought to be and to do. Luther felt, however, that so great was man's fall that not much empirical change would come over him as a Christian. The believer would love God and seek to serve him out of gratitude, but his actual renewal would be slight and fluctuating. Calvin believed that in salvation the believer was united to Jesus Christ by faith. By the power of the Holy Spirit he would be enabled to live in some measure according to the standard of Jesus Christ. Sanctification, therefore, played a greater role in Reformed and Presbyterian theology than it did in Lutheran thought. Likewise, because of a greater emphasis upon Christ's victory over sin and death in his resurrection and ascension, there was a greater stress upon the possibilities in the believer's life as he shared in Christ's victory. Tendencies toward activism among the Reformed and toward quietism among the Lutheran groups therefore emerged.

Predestination.—The doctrines of election and predestination have played so large a role in Reformed and Presbyterian thought that often they are regarded as peculiar to these churches. The problem, however, is rooted in the relationship of the freedom of God to the freedom of man, and as such it troubled biblical figures such as Jeremiah and Paul, early Church Fathers such as Augustine, and medieval churchmen as different as Aquinas, Bradwardine, and Wycliffe. Unless the God revealed in Jesus Christ is the ultimate God, completely free of any fate, destiny, or other external necessity, then there is no assurance that the Christian

gospel of love and forgiveness represents more than an optimistic hope in the face of unknown odds. But when the questions of man's freedom, of his responsibility, and of his aspirations are raised, the freedom of God seems to deny or to override man's freedom. Man seems to become merely a pawn in God's purposes. Throughout Christian history the debate has gone on among those who argued for the primacy of the divine freedom, for the primacy of human freedom (or usually human responsibility), or for various mediating positions. Luther, in debate with Erasmus, pushed the freedom of God almost to the extent of asserting a psychological determinism for man. William Tyndale, the English Bible translator, defended a rigorous Augustinian type of predestination against Sir Thomas More, the English humanist. Among all the early Protestant reformers it was regarded as axiomatic that the current Roman Catholic teaching about man's claim upon God by way of his merits undercut the whole Christian gospel.

Calvin's role in the doctrine of predestination was similar to his role in many Protestant ideas, that of a systematizer. Leaning heavily upon Augustine, he pushed the idea of God's freedom to the extent of saying that God was wholly free to save or to damn any man without regard to what men thought was just under the circumstances. This doctrine of "double predestination" was regarded by him as the only possible assurance a Christian could have that despite his sins and failures God would in the end save him. Later Calvinism pushed these ideas further, in the so-called doctrine of the decrees, to where it became the explanation of how and why men act as they do in history. As such it came close to determinism. Modern Protestantism seeks a solution of the problem in terms of the concurrent activity of God and man.

The Sacraments.—Because, Calvin asserted, it is God who seeks his prodigal children rather than they who seek him, and because it is God who directs his church in the life which it lives in his service, public worship is primarily the assembling of the people of God to hear what he has to say to them. They do not assemble to seek him but to meet him and to hear his word. When this takes place, they respond by receiving his love, his grace, his fellowship; and they present their prayers and petitions. The action of public worship was the hearing of the gospel and the joyful communion with God to which that gospel summoned men. By preaching and teaching, the gospel was to be made known and understood in the church. In the sacraments there were provided ways whereby men could actually appropriate and receive the grace offered in the gospel.

The sacraments in themselves possessed no particular powers. Whatever man received, he received by faith. The sacraments, therefore, are not independent of faith. They are rather a "lively preaching" intended to call forth faith. By this very fact they could not be considered necessary to salvation. Yet, since Christ commanded the church to carry out its mission in this manner, and since he did by means of the sacraments truly call forth faith, it was the duty of the church faithfully to use these "means of grace." Preaching and the sacraments could never be separated. A sacrament had three elements: the promise of God, its attestation or seal which showed that it had been fulfilled, and man's reception by faith of that which God had promised.

Baptism.—The promise of God in the gospel, Calvin said, is that God will forgive and receive into his fellowship those who have forsaken him. That promise was fulfilled, or sealed, when Jesus Christ came and was crucified and raised from the dead for man's redemption. What remains to be done is that man must actually return to the fellowship of God and become a member of the community of believers who make up the church, the body of Christ. This must be done as an act of faith, and under normal circumstances it is to be done through receiving baptism. Baptism symbolizes the death, burial, and resurrection of Christ. By accepting baptism, in an act of faith, men confess that they hope for salvation only in Christ and that they do in fact return to God. This is their part in the sacrament. God, then and there, "incorporates" the believer into the body of his Son, the church.

Calvin elaborated not a doctrine of infant baptism but a doctrine of Christian baptism, and then urged that children as well as adults might receive it. Children were to be given the promise

held out in baptism and then brought up to exercise such faith as their growing years and perception might enable them to do. Until they exercised faith their baptism would be incomplete. Yet, Calvin thought, since their salvation depended upon God's love and not upon baptism itself, they were safe in God's care while unable to exercise faith. Baptism was intended by God as an aid to faith, not as an indispensable rite necessary for salvation. God could, therefore, dispense with it if he chose. Men, however, were never to omit it, unless unable to use it.

Baptism could be administered by any method, immersion, sprinkling, etc., provided only that the method used clearly symbolized and proclaimed the death and resurrection of Christ. Baptism ought to take place only in the midst of the public worship of the church because it symbolized entrance into the Christian communion. Also, only those who lead in public worship should baptize. There could be no private baptism because there was no private salvation. There could be no "emergency baptism" because baptism had no such character about it as to create any emergency.

The Lord's Supper.—The Lord's Supper, Calvin believed, was instituted by God to support, nourish, and increase the faith of the Christian church. It was rooted in the event of Christ's death on the cross and symbolized that death. It proclaimed, therefore, the fact that God had fulfilled his promise and that men had been forgiven. Moreover, it invited men to "take," to receive, the offered mercy of God. Receiving the sacrament in an act of faith meant that one believed that God truly held out something to man in it and that man truly received in it just what God offered, namely, forgiveness, reconciliation, continued fellowship, and communion with God.

The elements (bread and wine) themselves had no particular merit or significance beyond their historical connection with Christ's last supper with the disciples. Nothing in the ritual changed the elements in any way. Christ was indeed present during the sacrament as he was present in preaching or in baptism. But his presence was not associated with the bread and wine. He was present to meet with and commune with his followers.

The setting for the sacrament demanded a table, Calvin said. Thus Christ instituted the sacrament, and thus it should be continued. The table symbolized the fact that God is offering to man and that man is to come, to receive; the altar, on the contrary, symbolized that man is offering something to God. Also, the sacrament belongs to the whole church, not to the ministers. It is to be administered only in the public worship of the congregation. All were to be invited to come. Any who feared they were "unworthy" were to know that only the confession of need could constitute worthiness. Those who came inwardly ungodly and unrepentant rejected God's mercy in the sacrament just as they rejected it when they heard it preached. Calvin believed that private communion, even for the sick, obscured the true nature of the church as a community and fostered superstitious ideas about the sacrament.

PRESBYTERY, in architecture, that portion of the chancel (q.v.) of a church in which the high altar is placed, and which is generally raised a few steps above the rest of the church. It is reserved for the priests and differs from the choir, the stalls in which are occasionally occupied by the laity. In Westminster

Abbey the space east of the transept is the presbytery, and the same arrangement is found in Canterbury Cathedral. In S. Clemente at Rome the presbytery is enclosed with a marble balustrade or screen.

PRESCOTT, WILLIAM HICKLING (1796–1859), U.S. historian noted chiefly for his dramatic accounts of the Spanish conquest of Mexico and Peru, was born in Salem, Mass., on May 4, 1796. His family had been prominent in Massachusetts history and was financially well off. After entering Harvard College in 1811 Prescott suffered an injury that caused him to lose the sight of his left eye; his other eye was later weakened by an infection, leaving him virtually blind. In spite of this handicap he determined to embark upon a literary career after he graduated from college. Sitting in a darkened room, he had the sources for his histories read aloud to him and did a large part of his writing with the aid of a device known as a noctograph. This was a tablet equipped with brass wires (to guide his hand) and with carbon paper on which he wrote with a stylus. Encouraged by his friend George Ticknor, who later became his biographer, Prescott turned to the study of Spanish history. With the aid of research assistants in Europe he obtained copies of thousands of books and documents and in 1837 published a 3-volume work entitled *History of the Reign of Ferdinand and Isabella, the Catholic*. It received enthusiastic reviews in Europe as well as in the United States. In 1843 his *History of the Conquest of Mexico* received even greater acclaim and eventually became one of the most widely read histories in the English-speaking world. Prescott finished his *History of the Conquest of Peru* in 1847 and then began work on the *History of the Reign of Philip the Second, King of Spain*, three volumes of which were completed by 1858; the next year, before finishing the fourth volume, he died of a stroke on Jan. 28.

With his vivid historical imagination, Prescott breathed life into the chronicles of the early Spaniards, yet he was passionately devoted to historical truth and did not sacrifice accuracy for interest or literary polish. His approach to history as a dramatic art had its shortcomings, such as lack of attention to certain details and occasional verbosity. Later anthropological research has corrected minor portions of Prescott's work on Mexico and Peru but on the whole his histories have stood the test of time and critical examination by scholars.

PRESCOTT, seat of Yavapai County in west central Arizona U.S., about 100 mi. NW of Phoenix, is located in a mile-high basin among pine-dotted mountains rich in minerals. Gold mining brought the first settlers; farmers and cattlemen followed. To protect them from Indian raids an army post, Ft. Whipple, was built in the 1860s about 17 mi. N of the present city, and in 1868 the first government of Arizona territory was set up near it. Later that year the fort and the government were moved to the area of the present city and the first legislature met in the "governor's mansion," a log-walled house preserved as a historic site.

The location of the capital alternated between Prescott and Tucson until 1889, when Phoenix was made the state capital. A railroad reached Prescott in 1893 and was extended to Phoenix in 1895.

Prescott is a trade centre for cattle ranches and farms in the valleys; mining also continues to be important, and small industries are increasing. The city was named for the historian William Hickling Prescott; founded in 1864, it was incorporated as a city in 1881 and in 1955 adopted a council-manager form of government. The inhabitants of Prescott boast that the rodeo staged by competing cowboys on July 4, 1888, was the first public rodeo to be given anywhere; over the years the celebration developed into a lively three-day event—Prescott Frontier Days. For comparative population figures see table in ARIZONA: Population. (A. M. P.)

PRESCRIPTION, in both domestic and international law is the effect of the lapse of time in creating and destroying rights.

It is also used in some philosophical writing such as Edmund Burke's to describe what legal philosophers would now call custom—that is, long-continued usage or habit as a source of law. Burke used long-continued beneficent working as the basis of law to refute the claim of philosophers of the French Revolution that the source of law is the present generation of people. The historical school of jurisprudence developed by Friedrich Karl von Savigny (*q.v.*) is similar. (See also JURISPRUDENCE.)

In law, custom as a source of law and prescription as a source of rights were originally two aspects of the same thing. They both required usage from time immemorial (beyond the memory of living man) as proof. In England and the United States, custom still continues as a source of law, but the phrase "time immemorial" in England has come to mean usage since 1189, the first year of the reign of Richard Coeur de Lion.

In Anglo-American law, prescription is distinguished from adverse possession; that is, the rights acquired from long-continued possession rather than use, such as a right-of-way acquired from use or a right to view as in *Ancient Lights* (*q.v.*) in England, which are called easements by prescription. English law gave a right of use if there was long-continued use, but on a legal fiction: if usage existed for a period as long as that prescribed in the statute of limitations for adverse possession, then it was presumed that there had once existed a now lost grant to use from the rightful owner. Most jurisdictions now have statutes just as applicable to long-continued usage as to long-continued possession, and the fiction of a lost grant, although available in some jurisdictions, is not used.

Modern justification of the concept of prescription is usually placed on three elements: law should reward the vigilant against the slothful; judicial administration should avoid the difficulties of proof, which long-continued delay in the assertion of rights occasions; and long-continued use does permit the inference of ownership, since right and use usually go together.

International law also has a concept of prescription: it recognizes a nation's claim to be valid by reason of long-continued assertion, and finds an abandonment of a claim by reason of long-continued failure to assert it. (A. Dm.)

PREŠEREN, FRANCE (1800–1849), the outstanding Slovene poet of the Romantic movement, was born at Vrba, near Lake Bled, Slovenia, on Dec. 3, 1800, the son of a farmer. He studied law in Vienna, where he acquired the familiarity with the mainstream of European thought and literary expression which, through him, reinvigorated Slovene literature. He later held posts in Ljubljana and Kranj as a civil servant and lawyer. His life was one of struggle and disappointment, and in 1835 the sudden death of his close friend, Matija Čop, and his unhappy love for Julija Prmic, brought him to the verge of suicide. He died at Kranj on Feb. 8, 1849.

Although Prešeren was not a prolific writer, his work gave new life to Slovene literature, the development of which had been checked by political and social conditions (see YUGOSLAV LITERATURE; *Slovene Literature*). The themes and prosodic structure of his verse set new standards for Slovene writers, and his lyric poems are among the most sensitive, original, eloquent, and aesthetically perfect works in Slovene. The varied poetic forms and metres, derived from foreign literatures, which he deliberately cultivated in his earlier lyrics, imposed no restraint on his own inspiration.

In his *Sonetni venec* ("Garland of Sonnets," 1834), inspired by his unhappy love, as in his later lyrics, he expresses the national consciousness which he sought to stimulate in his compatriots. His later lyrics (1841–43) are closer in rhythm to Slovene folk-poetry. He also wrote satirical verses (1845) on contemporary literary conditions in Slovenia. The epic poem, *Krst pri Savici* ("The Baptism by the Savica," 1836), dedicated to the memory of Matija Čop, treats the conflict between paganism and the early Slovene converts to Christianity, and illustrates Prešeren's patriotism, pessimism, and resignation.

See *Selection of Poems by France Prešeren*, trans. and ed. by W. K. Matthews and A. Slodnjak (1954). (V. J.)

PRESERVING OF FOODS: see FOOD PRESERVATION (IN THE HOME).

PRESIDENT, a term widely used to designate a person appointed or elected by a group or an organization to preside over its meetings and perform whatever managerial duties may be assigned to him. In the United States, president is the almost universal title of the head of a college or university. In Great Britain, though it is not so commonly used for that purpose, it does designate the heads of four of the colleges of Oxford and one of Cambridge's colleges. In the United States it is the title of the chief executive officer of business corporations, clubs, professional societies, and—most important of all—the federal government.

In early modern times the title came to be applied to the head of a division of a country, such as a dependency, city, or colony. Thus the title of the chief magistrate in some of the British colonies in North America was president. Such a colonial president was always associated with a colonial council to which he was elected and was therefore denominated president of the council of the colony. This title of president in the North American colonies was carried over into some of the state governments that were organized after the American Revolution. The title of president was used for the chief executives of the state governments of Delaware (1776–92), New Hampshire (1784–92), Pennsylvania (1776–90), and South Carolina (1776–78). Since 1792, however, the title of the chief executive of every state in the United States has been governor.

With rare exceptions the title president is used in republics throughout the world to designate the officer in whom the executive power is vested. The president of a republic inevitably has some of the functions of the head of a monarchical government and is, in fact, the chief of state. The title "President of the United States" is even older historically than the office of president of the United States, the chief executive prescribed by the Constitution framed in Philadelphia in 1787. It was applied to the officer who presided over the sessions of the Continental Congress and of the Congress under the Articles of Confederation. As this officer had no executive duties, the office was in no proper sense a predecessor of the present office of president of the United States. The framers of the Constitution in 1787 adopted the title president to designate the very different office in which they vested the authority of the chief executive of the United States.

UNITED STATES

The framers of the federal Constitution provided for the office of president in one succinct sentence: "The executive power shall be vested in a President of the United States of America" (Art. II, sec. 1). The very brevity of this provision has afforded ample opportunity for the evolution of the presidency into the extraordinary office it has become.

Election.—The Constitution provided for the election of the president by special presidential electors. Each state was to appoint "in such Manner as the Legislature thereof may direct, a Number of Electors, equal to the whole Number of Senators and Representatives to which the State may be entitled in the Congress" (Art. II, sec. 1). Every state legislature has surrendered its right to choose electors and has provided that its electors shall be chosen by popular election on a general ticket nominated by each party. Whichever party receives the most votes for its list of candidates for presidential electors wins all the electoral votes of that state.

The Constitution requires that the presidential electors shall vote by ballot for president and vice-president in their respective states and send the certified result of their balloting to the president of the U.S. Senate. According to a 1934 act of Congress, the electors vote on the first Monday after the second Wednesday in December. The votes are then counted before a joint session of the Senate and House of Representatives and the candidates receiving a majority for president and vice-president are declared elected. In case no candidate for president receives a majority, the House of Representatives votes on the three candidates receiving the highest number of electoral votes, with each state delegation casting a single vote. The Senate—each member casting one vote—elects the vice-president if no candidate for that office receives a majority of the electoral votes.

An almost inflexible custom since the election of 1800 had induced presidential electors to cast their ballots automatically in accordance with the expectation of the voters who had elected them, but since 1948 that usage has not been universally followed. In the 1960 election 15 Democratic presidential electors cast their ballots for Sen. Harry F. Byrd of Virginia instead of for the presidential candidate of the Democratic Party, Sen. John F. Kennedy.

With rare exceptions, such as the Hayes-Tilden election in 1876 and the Cleveland-Harrison election of 1888, the electoral college has elected the candidate with either a majority or at least a plurality of the popular vote. The majority cast by the electoral college is almost always much greater for the victor than his popular majority or plurality. In 1960, for example, Kennedy's popular vote was less than two-tenths of one percent greater than his opponent's but his vote in the electoral college was almost 16% greater.

Candidates for president are nominated by each major party at a national nominating convention consisting of more than 1,000 delegates representing party members in every state, the District of Columbia, and the possessions. The delegates convene in some selected city during the summer preceding the presidential election. Aspirants to the presidency usually have participated in pre-convention campaigns in states holding presidential primary elections, seeking to win delegates who will support them in the national convention. Each convention adopts a party platform before the balloting of the delegates to select its presidential and vice-presidential candidates. (See NATIONAL CONVENTION.)

The strategy of each party is to endeavour to win the big blocs of electoral votes of the more populous states such as New York, Illinois, or California in order to accumulate the majority of electoral votes necessary to elect. As a result, presidential candidates are usually nominated from such states. Following the nominating conventions, the presidential candidates tend to concentrate their campaigning in these populous states, especially those that have a habit of swinging from one major party to the other. Half the candidates for president in the century following the American Civil War were or had been governors of such states.

Requirements and Salary.—The Constitution requires that the president be a natural-born citizen of the United States and be not less than 35 years old. A president must have been a resident of the United States for 14 years at the time of his inauguration, though such residence need not have been continuous. The Constitution also provides that the president shall receive a compensation for his service that shall neither be increased nor diminished during his term. Congress in 1949 fixed the presidential salary at \$100,000 a year plus an allowance of \$50,000 to assist in defraying expenses resulting from official duties. Both amounts are taxable. The president may also draw up to \$40,000 a year for travel expenses and official entertainment, and this sum is not taxable. Former presidents are provided with a lifetime pension of \$25,000 a year and a \$50,000 expense fund. Widows of presidents receive \$10,000 per year.

Two-Term Limit.—The president is elected for a four-year term but the Constitution originally placed no limit on the number of terms a president might serve. Alexander Hamilton, in *The Federalist*, argued for unlimited reeligibility. Washington opposed placing any limit on the number of terms a president might serve and, by retiring at the end of his second term, he had no intention of setting a precedent. Thomas Jefferson was the first president (1801–09) who favoured setting a precedent for only two terms and during the next 130 years the two-term limit was assumed to be permanently established by an inflexible custom.

As the presidential campaign of 1940 drew near, however, the electorate became deeply concerned over the threat to the security of the United States by the war then raging in Europe. Pres. Franklin D. Roosevelt's second term was drawing to a close. The Democratic national convention nominated him for a third term, apparently on the assumption that a change of administration would not be prudent in the midst of a world crisis that might suddenly involve the United States in war. Roosevelt was elected for a third term in 1940 and for a fourth term in 1944, thereby shattering the long-standing two-term precedent.

As part of the postwar reaction against strong executive leader-

ship, the 22nd Amendment to the Constitution was adopted in 1951 to limit the president to two terms: "No person shall be elected to the office of the President more than twice, and no person who has held the office . . . or acted as President for more than two years of a term . . . shall be elected to the office . . . more than once." Pres. Harry S. Truman was exempted.

Inauguration.—On assuming office the president takes the oath of office prescribed by the Constitution: "I do solemnly swear (or affirm) that I will faithfully execute the Office of President of the United States, and will to the best of my Ability, preserve protect and defend the Constitution of the United States." This oath is administered by the chief justice of the United States. Since Washington's day every newly inaugurated president has delivered an inaugural address describing the basic policies he plans to follow.

Impeachment.—The president is not subject to judicial process despite the silence of the Constitution on the matter. This immunity is derived by judicial interpretation from the implied separation of powers of the Constitution, which signifies that the judiciary may not interfere with the executive. However the president, along with other civil officers of the United States may be impeached and, if convicted, removed from office. The House of Representatives initiates impeachment proceedings against the president by passing resolutions consisting of articles of impeachment charging him with "Treason, Bribery, or other high Crimes and Misdemeanors." "Managers" appointed by the House of Representatives prosecute the accused president on trial before the Senate sitting as a court, with the chief justice presiding when the president is on trial. The president is not present in person but is defended by his legal counsel. Conviction requires a two-thirds vote of the senators. The only penalty the Senate can impose is removal from office. Pres. Andrew Johnson (q.v.) was impeached and tried but the Senate, by a margin of a single vote did not find him guilty. The trial of Johnson was so manifestly animated by passion and prejudice that it severely damaged the device of impeachment as a check on the president.

Vice President.—The vice-president is elected with the president and for the same term. The Constitution provides for vice presidential succession to the presidency when that office is vacant. It also originally provided that: "In Case of the . . . Inability [of the president] . . . [his] Powers and Duties . . . shall devolve on the Vice President . . ." But no authority to determine presidential inability was named. Thus, during the invalidism of Pres. Garfield in 1881 and of President Wilson in 1919, and the illness of President Eisenhower, official functions of the president were virtually suspended. To provide for both offices becoming vacant Congress in 1947 determined the succession goes first to the speaker of the House of Representatives, next to the president pro tempore of the Senate, and then to cabinet members in the order their departments were created. In 1967 the 25th amendment provided that the vice-president succeeds to the presidency if the president declares his inability to the president pro tempore of the Senate and the speaker of the House, or if the vice-president and a majority of the cabinet declares the inability. Presidential notice of no inability goes to the same congressional officers and is effective unless contested by the vice-president and a majority of the cabinet, or a body designated by Congress; then a two-thirds majority of both houses can overrule the president. If the vice-presidency is vacant the president appoints a vice-president subject to confirmation by a simple majority of both houses. Succession on the simultaneous vacancy of both offices remains governed by the act of 1947.

President as Chief Executive.—The Constitution makes the president the nation's chief executive with this succinct injunction: "... he shall take Care that the Laws be faithfully executed" (Art. II, sec. 3). He performs this duty through the elaborate system of executive agencies created by Congress under its constitutional power "To make all Laws which shall be necessary and proper carrying into Execution" the powers vested in Congress and powers vested in the other branches of the federal government under the Constitution.

As the president is responsible for seeing to it that the laws be faithfully executed, the Constitution vests in him the power

nominate and, by and with the advice and consent of the Senate, to appoint all but inferior executive officers. He may "fill up all vacancies that may happen during the Recess of the Senate, by granting Commissions which shall expire at the End of their next Session." Usually, but not always, the Senate confirms these recess appointments. Customarily the Senate confirms the president's nominations of cabinet appointees without question. The Constitution is silent as to the president's power to remove appointees without the consent of the Senate. The first Congress (1789-91) assumed without legislative action that he could not be held responsible for enforcing the laws unless he had the unrestricted power to remove subordinates in whom he did not have confidence. This interpretation was not definitively determined by the U.S. Supreme Court until 1926 (*Myers v. United States*, 272 U.S. 52). Congress has, however, created a number of independent agencies such as the Federal Trade Commission and invested them with quasi-legislative and quasi-judicial functions. The president's power to remove members of these commissions is somewhat restricted.

The Constitution provides that "The President shall be Commander in Chief of the Army and Navy of the United States, and of the Militia of the several States, when called into the actual Service of the United States" (Art. II, sec. 2). He is commander in chief in time of peace as well as in time of war. He has at all times unlimited authority to direct movements of land, sea, and air forces. This unlimited discretion enables a president to direct movements of the armed forces that may provoke hostilities with a foreign nation and leaves Congress no alternative but to declare that a state of war exists. Thus President Polk in 1846 ordered U.S. troops into disputed territory at the Mexican border where a clash with Mexican troops initiated the Mexican War.

President Lincoln gave the commander in chief power an extraordinarily broad interpretation during the American Civil War as he utilized armed forces to fulfill his constitutional obligation to "take care that the laws be faithfully executed" throughout the entire nation. To this end he suspended the privilege of the writ of habeas corpus, increased the personnel of the Army and Navy, acquired vessels for the Navy, proclaimed emancipation of the slaves, and initiated his own plan of reconstruction of the states whose citizens had been in rebellion—all powers generally assumed to belong to Congress. Lincoln asked Congress to authorize retroactively some of his acts, and it did so. Clinton L. Rossiter has summed up the situation by saying that since the Supreme Court "regards the war powers of Congress as limited only by the necessities of the case, which are for Congress to ascertain, there is apparently nothing the President cannot do constitutionally if war should strike the country." (*The Supreme Court and the Commander in Chief*, pp. 101-102, Cornell University Press, Ithaca, New York, 1951.)

The Constitution empowers Congress "To provide for calling forth the Militia [of the states] to execute the Laws of the Union, suppress Insurrections and repel Invasions" (Art. I, sec. 8). The president may have in the meantime also used the federal armed forces for these purposes. There was no federal army when Congress enacted the legislation in 1794 that enabled President Washington to assemble 15,000 state militiamen and suppress the revolt in western Pennsylvania against collection of the federal excise tax on whisky stills. In 1861 President Lincoln interpreted the secession movement in the very phrases of the statutes of Washington's administration when he called upon the governors of the states for 75,000 militiamen to suppress combinations obstructing the enforcement of federal laws in states that had passed ordinances of secession. In 1957 President Eisenhower, utilizing the power Congress had authorized, mobilized the militia of Arkansas under his power as commander in chief, thereby taking it out of the control of Gov. Orval Faubus, who had been defying a federal court order. President Eisenhower then utilized federal armed forces to prevent further interference with the court order which directed limited desegregation in a school at Little Rock, Ark.

Foreign Relations.—The Constitution invests the president with "Power, by and with the Advice and Consent of the Senate, to make Treaties, provided two thirds of the Senators present con-

cur" (Art. II, sec. 2, clause 2). Usage has established the practice that the president, either directly or through his agents, negotiates treaties and submits them to the Senate for action. In addition to treaties the president frequently negotiates with foreign governments executive agreements which are not referred to the Senate but have all the effect of treaties.

"The President is the sole organ of the nation in its external relations and its sole representative with foreign nations," declared John Marshall as a member of the House of Representatives in 1799. The Constitution provides that the president, "by and with the Advice and Consent of the Senate, shall appoint Ambassadors, other public Ministers and Consuls" (Art. II, sec. 2), who become, in effect, the president's personal diplomatic representatives abroad. Only the president can "receive Ambassadors and other public Ministers" whereby foreign governments are recognized and diplomatic relations with them are maintained. Only the president can dismiss foreign diplomatic representatives.

Pardons and Reprieves.—The Constitution provides that the president "shall have Power to grant Reprieves and Pardons for Offenses against the United States, except in Cases of Impeachment." A "reprieve" suspends the penalties of the law while a "pardon" remits the penalties. The president may not grant a pardon before the commission of an offense but may do so at any time after its commission. Since impeachment and conviction of officers of the United States is an exclusive function of Congress, the president is forbidden the power of pardon in such convictions. In like manner Congress may not interfere with the president's power of pardon.

Cabinet.—The president's cabinet grew unexpectedly out of the provision of the Constitution that the president "may require the Opinion, in writing, of the principal Officer in each of the executive Departments, upon any Subject relating to the Duties of their respective Offices" (Art. II, sec. 2). President Washington at first followed this provision explicitly and obtained the opinions in writing. Later, with no idea that he was initiating a cabinet, he began holding informal conferences with these heads of the executive departments. In the course of time these random conferences became habitual and regular meetings and thus the cabinet as an institution was firmly established. The president's cabinet constitutes a purely advisory group with no collective authority. The weight of its influence varies greatly with the theory and practice of different presidents. President Lincoln ignored its opinion whenever he chose, while President Pierce is said to have based some decisions on a majority vote of his cabinet.

Ceremonial Duties.—With the passage of time the president has become increasingly burdened with ceremonial duties. The elaborate ritual of his inauguration, suggestive of a royal coronation, is but the first of such activities. He awards medals to military heroes, buys the first poppy at the annual Veterans of Foreign Wars sale, greets delegations of firemen, Boy Scouts, Elks, Eagles, Daughters of the American Revolution, and other organizations, issues the Thanksgiving Proclamation, lays a wreath on the Tomb of the Unknowns, lights the White House Christmas tree, and receives visiting monarchs. Nor can it be doubted that these acts of the chief of state strengthen the powers of the chief executive. More than once the electorate has chosen as president a symbol rather than one who, by an appropriate apprenticeship in public administration, has been prepared for the presidency.

Origin and Early History.—Historically the office of chief executive of the states at the time of the framing of the Constitution of the United States, the state governors, provided the model for the office of president; the framers lifted several provisions for the office of governor from state constitutions and put them in Article II, which prescribes for the presidency. For example, just as the constitution of every state made its governor commander in chief of its military forces, so the president was made commander in chief of the armed forces of the nation.

No sooner had President Washington been inaugurated than the office began its evolution, continuous ever since, shaped by the influence of events and the personalities of the presidents. Washington's secretary of the treasury, Alexander Hamilton, with Washington's willing acquiescence, assumed bold headship of the execu-

tive departments. He drafted and promoted passage through Congress of the administration measures known ever since as the Hamiltonian program. But Hamilton's competent and aggressive leadership, no less than the very nature of the legislation he had enacted, aroused a determined opposition. Rallying around Thomas Jefferson, this opposition formed the first Republican Party, elected Jefferson president in 1800, and brought about a striking change in the very nature of the presidency. The centre of gravity in the federal government passed from the executive to the Congress, with President Jefferson managing congressional legislation through his personal influence as an astute party leader. Jefferson had initiated what turned out to be a quarter century of congressional government under the "Virginia dynasty" of three two-term presidents: Thomas Jefferson (1801-09), James Madison (1809-17), and James Monroe (1817-25). By the 1820s the president seemed to have become practically the agent of Congress.

Late in the 1820s, with white manhood suffrage almost universal, the voters rallied under and elected president a military hero, Gen. Andrew Jackson, who assumed that he was a tribune of the common man and had a mandate to act as his protector. Jackson imposed his imperious will on the Congress and so shifted the centre of gravity in the government back to the executive branch, where it had been in Washington's administration. The presidency had taken another sharp turn. To this day the office bears the impress made on it by the personality of President Jackson (1829-37). But even more than Jackson, President Lincoln (1861-65), in the crisis of the American Civil War, utilizing the unexplored power of commander in chief, reshaped the presidency into an instrument of extraordinary power for resolving crises and great emergencies, all with a confident touch and an incomparable ingenuity in dealing with them. Historians, with virtual unanimity, rank Lincoln first among all the presidents.

20th Century—With the beginning of the 20th century the presidency, after a generation-long decline of the high prestige Lincoln's hand had given the office, experienced a revival of the executive leadership in legislation which Hamilton had given it in the first years of the republic. Pres. Theodore Roosevelt (1901-09) believed that "a good Executive under present conditions of American life must take a very active interest in getting the right kind of legislation." As a consequence of his extraordinary ability to dramatize public issues and bring public opinion to bear on Congress, the number and importance of legislative accomplishments in his administration had scarcely been surpassed by any previous administration.

It was Pres. Woodrow Wilson (1913-21) who brought to the presidency a well-matured and clear-cut formula for presidential leadership in legislation. Utilizing the hitherto neglected provision of the Constitution that the president "shall from time to time give to the Congress Information of the State of the Union, and recommend to their Consideration such Measures as he shall judge necessary" (Art. II, sec. 3), he proceeded to demonstrate his legislative leadership by getting an unprecedented program of important measures, regulative of business, enacted by Congress in his first term. Wilson gave a dramatic touch to his leadership by resuming the delivery of presidential messages in person, something that had not been done since the administration of John Adams 112 years earlier. In the 1920s Howard L. McBain was to note the new trend in the unqualified statement: "The prime function of the President is not executive. It is legislative." The proof of this is demonstrated by the fact that presidential campaigns are primarily competitions between the two major party candidates for president, each trying to outbid his opponent on policies he proposes to induce the Congress to enact into law if he is elected.

Pres. Franklin D. Roosevelt (1933-45) introduced new features into the pattern of presidential leadership in legislation. There was the "fireside chat," an informal talk broadcast by radio to the nation; its purpose was to encourage the public to induce Congress to enact measures in the president's program. It became an established device and was fortified in later years by the use of television. Franklin D. Roosevelt also initiated the practice of accompanying a proposal for legislation with an already prepared bill. Although patronage is no longer so abundant, what is avail-

able is still utilized by resolute presidents to reward administration supporters of their programs by appointing their constituents to desirable federal jobs while withholding patronage from dissident party members.

If the president decides not to sign a bill passed by both houses of Congress but to veto it, that is, return it to the house in which it originated along with his objections to it as the Constitution directs, it may still become a law by a two-thirds vote of both houses. In the hands of a shrewd president this veto power may become a decisive and even positive force in legislation; if the president is known to be ready to veto certain measures the legislators may decide to reshape them to meet his objections. No one can say just how much a president's known or even suspected objections to this or that provision of a pending bill may induce a congressional committee to recast it in the hope of avoiding a possible veto.

The Constitution provides that the president "may, on extraordinary Occasions, convene both Houses, or either of them, and in Case of Disagreement between them, with Respect to the Time of Adjournment, he may adjourn them to such Time as he shall think proper" (Art. II, sec. 3). The president has never had occasion to adjourn Congress. The Senate has frequently convened immediately after inauguration of a new president to consider and confirm his nominations of officers, especially his cabinet. The House of Representatives has never been called into session alone.

The sudden growth in magnitude of the presidency in mid-20th century constitutes a landmark in the history of the office. With the sharp decline in isolationism in the late 1930s and after World War II, and the sudden plunge of the United States into the midst of world politics, the very nature of the presidency underwent a profound change. War, both hot and cold, had shifted the centre of gravity of the presidency from the domestic field into the vortex of world problems with the attention of the human race centred on the president of the United States. Questions of foreign aid designed to rescue the critical economies of recent allies from impending collapse, of whether to meet Communist aggression with armed force in Korea or to use it in the Near East, whether to rescue Greece and Turkey from impending inclusion in the Communist sphere, or even to be ready at any moment to order the use of nuclear weapons—all this and more put on the presidency an unprecedented burden of responsibility. Meanwhile new domestic issues with worldwide implications such, for example as desegregation riots, added to the president's responsibilities.

Some measure of the growing burden of the presidency can be seen in the fact that Pres. Grover Cleveland in the 1880s managed the office with a single secretary—when he had any at all—and answered the telephone in person. In 1960 the executive office of the president comprised half a dozen agencies with a total personnel of 2,814, while one of the agencies, the White House Office—the president's immediate staff and thus the counterpart of Cleveland's single secretary—had a personnel of over 400. With it all the president is overburdened. Whatever responsibility the Constitution vests in him cannot be shifted.

LATIN AMERICA

Latin-American governments provide the most numerous examples of presidential government since that type was initiated by the Constitution of the United States. The single exception to the presidential type of government in South America is Uruguay, whose executive consists of a council of nine. Some Latin-American constitutions show a slight trace of a parliamentary system where they prescribe that cabinet members, in contrast with those in the United States, may appear on the floor of the legislature to speak and explain their programs. Actual premiers, however, are conspicuously absent in Latin America.

Latin-American presidents are elected either indirectly by electoral colleges after the general pattern of the United States or directly by the voters. The presidential term of office in Latin-American republics varies from nation to nation with the number of terms of office frequently limited and successive consecutive terms sometimes forbidden. Often these presidents are genuine political leaders functioning in the democratic tradition as duly

elected public officials after the manner of strong presidents of the United States. Other Latin-American presidents have been military adventurers ambitious for power who after election have seized control and continued in office beyond their constitutional term under the pretense of emergency. Sometimes the president is an ambitious civilian who prolongs his term arbitrarily. There have been Latin-American presidents who were obviously virtual puppets of the army or of powerful economic interests, or of some clique which put them in office and made decisions for them.

The legal authority of a Latin-American president consists of the power vested in him by the constitution and laws. His main responsibility is to head and direct the executive branch of the government. He has the authority to nominate major executive officials under him, usually with the requirement of confirmation by a branch of the legislature. He recommends measures to the legislature, receives foreign ministers, and carries on relations with foreign nations. He is dependent on the legislature for appropriations and for ratification of the international agreements he makes, and he is subject to impeachment by the legislature. He is commander in chief of the nation's armed forces and has the power of pardon. The Latin-American presidency is modeled after that of the United States no matter how differently it functions in an alien culture.

FRANCE AND OTHER COUNTRIES

France's imitation of the U.S. office of president was a consequence of the Revolution of 1848 when the government of King Louis Philippe was overthrown and the Second Republic was established with a constitution that provided for a president elected by universal manhood suffrage for a term of four years. Louis Napoleon, a grand-nephew of the first Napoleon, was elected first president, but before the end of his four-year term arbitrarily extended his term to ten years and less than a year later directed a plebiscite which voted him emperor for life (1852). But when, in the short Franco-German War (1870-71), France was overwhelmed, Napoleon III was utterly discredited and the French conception of the office of president was profoundly affected by Napoleon's conduct following his election to it by popular vote.

The constitution of the Third Republic that followed the collapse of the Second Empire rejected popular election of the president and provided for his election by a joint vote of the two houses of parliament. The term was set at seven years with no limit on reeligibility. The new constitution gave the president an imposing list of powers, none of which he could exercise except on the advice of his ministers. His every official directive had to have the countersignature of a minister in order to be valid. The folly of President Louis Napoleon had thus emasculated the office of president in France. As Sir Henry Maine put it: "The constitutional King . . . reigns but does not govern. The President of the United States governs but does not reign. It has been reserved for the President of France that he neither reigns nor rules." France had, in fact, turned from the presidential type of government of the United States and Latin America and returned to parliamentary government. In the absence of significant authority the presidents of France, during the Third and Fourth republics, had to rely upon the use of whatever influence and political skill they had.

The constitution of the Fifth Republic of France, adopted in 1958, created a formidable office of president under the influence of Premier Charles de Gaulle. As the framers of the U.S. Constitution in 1787 had shaped the office conscious of the fact that General Washington would be its first incumbent, so the constitution of the Fifth Republic shaped the presidential office in France for General de Gaulle. It therefore stands in sharp contrast with the president elected by and subservient to parliament. At first elected by the members of the two houses of parliament, the general councils of the departments (virtually counties), and representatives of the municipal counties, totaling in all more than 80,000 electors, the president, after an amendment in 1962, is elected by direct universal suffrage.

The president of the Fifth Republic of France appoints the premier, who then nominates a ministry or cabinet that the presi-

dent appoints. When a ministry falls as a consequence of an adverse vote of parliament the president accepts the premier's resignation. He has a suspensive veto over acts of parliament. This veto merely requires parliament to reconsider its vote, but re-passage by a majority vote validates the act. If parliament so proposes, the president may submit a bill to a referendum. The constitution gives the president the power to dissolve a parliament, but he may not exercise this power during the first year after its election. While the president must consult the premier and the presidents of the assemblies on a decision to dissolve a parliament, he need not heed the advice. Under a resolute president the power of dissolution may be very significant. The president of France has the power to appoint high civil and military officials. He is commander in chief of the armed forces of France. He is authorized to send messages to parliament which it must debate at once, and he may convene parliament in special session to hear and consider a message. Emergency power is vested in the president of France "to take those measures which circumstances demand when the institutions of the Republic, its independence or the integrity of its territory or the fulfillment of its international obligations threaten a grave crisis and when the regular functioning of constitutional authority is interrupted."

Next to the president of France the most significant office of that title in Europe is the president of the Federal Republic of Germany. This office is almost a replica of the weak presidency of France during the Third and Fourth republics. He is elected by a special convention composed of the *Bundestag* (lower house of parliament) plus an equal number of delegates elected by the popular branch of the *Länder* (states) of the federal union. The president's term of office is five years and he may be reelected only once. The influence of earlier French constitutions is seen in the provision that official acts of the German federal president must be countersigned by the chancellor (prime minister) or other appropriate minister. The president appoints and dismisses the chancellor but these acts require the approval of parliament.

With rare exceptions the titular head (and sometimes actual chief executive) of nearly all other European governments bears the title of president. The constitutions of Finland and Portugal provide for the election of the president by electoral colleges while in Austria and Italy he is elected by the parliament. In contrast to the republics of North and South America, European republics weaken the presidential power by vesting executive authority in cabinets responsible to parliaments. The president of Switzerland is in reality the president of the federal executive council, which is elected by the assembly and is invested with the executive power of the nation. However, the Swiss president may make decisions in the name of the federal council in cases of emergency, and he exercises general supervision of federal administration. In the communist governments of Europe, designated as people's republics, the head of the state bears the title of president.

PRESIDENTE HAYES, the southernmost of the three departments which make up the Paraguayan Chaco, is for 250 mi. adjacent to the Argentine province of Formosa, from which it is separated by the Pilcomayo River. The latter is the longest of many parallel watercourses draining the department eastward to the Paraguay River. Although mainly a marshy plain with thickets of scrub forest, the department contains alluvial areas adjacent to the Paraguay near Asunción which produce sugar, corn, and cotton. Villa Hayes, the capital, is named (as is the department) after Rutherford B. Hayes, the U.S. president whose arbitration settled the boundary between the Argentine and Paraguayan Chacos. The department has an area of 22,579 sq.mi. Population ([1962] 31,572) is sparse and communications are poor.

(G. J. B.)

PRESOV (Hung. EPERJES), the third largest town of Slovakia, in the East Slovak kraj (region), Czech., lies on the Torysa River 25 mi. (40 km.) N of Kosice. Pop. (1961) 37,534. Presov's position in the Kosice Basin is its main asset, since this region provides an easy approach from the south northward to the Carpathians.

The town was founded in the 12th century by German immigrants, and was one of the group of 24 settlements (Spis or Zips) along the trade route from east Hungary to Poland. Most of Presov was rebuilt after a devastating fire in 1887, but the medieval oval-shaped marketplace remains. There is a fine 18th-century Greek Catholic cathedral, and the town is traditionally a meeting place and cultural centre of the Slovaks and Ruthenes; the emphasis on Ruthenian culture remains.

Presov's industrial activity is new; its traditional economy was that of trade in wheat, cattle, and salt. The salt mines at Solivar nearby supply about one-fourth of Czechoslovakia's needs. At Dubnik, 15 mi. E, is the only opal mine in Europe (now abandoned). Presov has grown vigorously since World War II with the industrial development of electrical engineering, textile production, and food processing. The town is an important rail and road junction for the Carpathians and Poland, and there are regular air services to Prague and Bratislava. (H. G. S.)

PRESS ASSOCIATION: see NEWS AGENCY.

PRESSBURG: see BRATISLAVA.

PRESS SYNDICATE, an organization formed to spread the cost of expensive features among as many newspapers (subscribers) as possible. Press syndicates sell the exclusive rights to a feature to one subscriber in each territory in contrast to the wire news services (see NEWS AGENCY), such as the Associated Press, United Press International, and Reuters, which offer their reports to all papers in a given area.

Irving Bacheller of Brooklyn, N.Y., started the first modern syndicate in 1883; it offered and distributed fiction and articles about housekeeping. In 1884 S. S. McClure (who later established *McClure's Magazine*) founded the syndicate that still bears his name. He first offered fiction and secured the rights to several stories by Rudyard Kipling which were widely published. He also helped to introduce the stories of Sir Arthur Conan Doyle and others into the United States.

The features then offered were mostly literary material and pictures (see PHOTOJOURNALISM: *Syndicates and Agencies*). An important change came in 1896, however, when the big New York Sunday newspapers began to produce and publish comic pages such as "Foxy Grandpa," "The Yellow Kid" (originally called "Hogan's Alley"), and "Li'l Mose." In 1907 the comic strip (see CARICATURE AND CARTOON) in daily papers was introduced. Two artists, "Bud" Fisher and George Herriman, were credited with drawing the first strips, though an earlier strip by Clare Briggs had a brief run in Chicago. This form of art gradually changed the whole character of the business and made it more profitable. The strips were shipped in matrix form to the subscribers for simultaneous publication. Originally they were truly "comics" in that they were intended to make readers laugh, but later many became continued stories with no humour. When Fisher's "Mutt and Jeff" was first bought and published in England in 1920 many British readers scoffed at the idea. It proved successful and English editors later originated many strips in competition with the U.S. products. By the latter 1950s U.S. comics were being translated into several languages and sold all over the world.

Before the modern syndicate was developed there had been a few sporadic efforts to distribute political and fashion letters. In 1875 A. N. Kellogg of Chicago began to sell stereotyped plates carrying literary and pictorial material to weekly papers. Kellogg was followed in this technique by Major O. J. Smith in England (1882) and by directors of political parties and factions in Germany.

In the 1960s a great variety of material was available from press syndicates, including columns on a wide range of subjects, dress patterns, crossword puzzles with substantial prizes offered for the correct solution, etc. Several newspaper chains had their own syndicates.

The leading syndicates in the 1960s were King Features, owned by the Hearst Papers; United Features, an offspring of Scripps-Howard; Bell-McClure Syndicate; A.P. Newsfeatures; General Features; and Chicago Tribune-New York News Syndicate. Prominent British syndicates were Central Press, Exchange Telegraph Co., Ltd., and Incorporated Press of Great Britain.

(F. L. M.; J. N. W.)

PRESSURE CHEMISTRY is the study of the pronounced influence of pressure on both the physical and chemical states of matter and on the changes that matter undergoes in industrial chemical processes. The Haber process for the synthesis of ammonia from hydrogen and nitrogen, developed in Germany prior to World War I by the Badische Anilin und Soda Fabrik, was the first industrial chemical process to use high pressure for a chemical reaction. Many other substances are manufactured under conditions which include elevated pressure. These include methanol, ethanol and other alcohols; phenol, polyethylene, amines, and naphtha or gasoline from coal or gas. Pressure, which ordinarily changes a gas or vapour into a liquid, is used in the production of oil from wells, in purification and separation operations and in changing carbon into diamond.

Pressure performs several functions. It has an effect on some chemical reactions so that at equilibrium a greater amount of product is formed. It causes some reactions to take place at a faster rate, so that much more of the desired product is formed in a given time. It may maintain water or organic substances in a liquid state at a higher temperature than would be possible under ordinary pressure. This is beneficial in some chemical reactions.

Chemical Equilibrium.—According to H. L. Le Châtelier's principle, when a system at equilibrium is subjected to a constraint, the system will change in a manner to oppose the constraint. Thus when a system in chemical equilibrium is subjected to pressure it will react to reduce its volume. Pressure favours a chemical reaction in which the volume of the products is less than that of the reactants. The effect of pressure on chemical equilibrium may be stated more precisely in terms derived from thermodynamics, e.g., the reaction of hydrogen and nitrogen to form ammonia is favoured when it is carried out under elevated pressures. This reaction is $1/2\text{N}_2 + 3/2\text{H}_2 \rightleftharpoons \text{NH}_3$. Each mole of ammonia is formed from two moles of hydrogen and nitrogen and, according to Le Châtelier's principle, the reaction is favoured by elevated pressure. The fugacity f may be considered as a corrected pressure for each of the elements and compounds involved in the reaction. The ratio of the fugacities, as expressed below, must have a value fixed by the temperature according to the equation by Samuel Glasstone:

$$RT \ln \left[\frac{f_{\text{NH}_3}}{f_{\text{H}_2}^{3/2} f_{\text{N}_2}^{1/2}} \right] = 9,130 - 7.46T \ln T + 3.69 \times 10^{-4} T^2 - 0.235 \times 10^{-6} T^3 + 12.07 RT,$$

where R is the gas law constant in cal./ (gram-mole \times $^{\circ}\text{K}$.) and T is in $^{\circ}\text{K}$. From this equation the extent to which the reaction proceeds may be determined. Starting with a mixture of 3 moles of hydrogen to 1 mole of nitrogen, the resulting mixture will contain 3.85% ammonia at equilibrium under 10 atm. pressure, 25.1% under 100 atm. and 79.8% under 1,000 atm., all at 400°C . This illustrates the effect of increasing pressure in forming more ammonia at equilibrium.

Pressure has a similar effect on the equilibrium between carbon monoxide and hydrogen to form methanol, according to the reaction $\text{CO} + 2\text{H}_2 \rightleftharpoons \text{CH}_3\text{OH}$.

Rate of a Chemical Reaction.—A chemical reaction may reach equilibrium slowly or quickly. In many industrial processes it is important that reactions take place quickly, and pressure sometimes increases the rate of reaction.

For example, when ammonia is formed in a reactor under identical conditions except that the pressure is varied, the rate of formation is 1 mole/(hr. \times cu.ft. of catalyst) at 100 atm. and 10.5 mole/(hr. \times cu.ft.) at 300 atm., representing a 10.5-fold increase in the rate of the chemical reaction as a result of a 200 atm. increase in the pressure.

Effects on the Physical State.—A pressure of 5,000 p.s.

(pounds per square inch) is used to maintain a mixture of chlorobenzene and sodium hydroxide solution in a single liquid phase at 360°C . Under these conditions, a reaction occurs which produces sodium phenolate. The latter is neutralized with hydrochloric acid to produce phenol. In this process the caustic soda solution and chlorinated benzene are mixed and passed through a heated pipe autoclave under pressure. The pressure increases the mutual solubility of the components of the reaction mixture and provides suitable conditions for the hydrolysis of the chlorobenzene. This illustrates the action of pressure in maintaining a liquid phase.

The phase relation between liquids and vapours in equilibrium is often complex when mixtures of several components are considered. Mixtures of hydrocarbons under pressures as high as 10,000 p.s.i. are found in oil and gas wells. Normally, a vapour phase is formed when the pressure on a liquid mixture is decreased or when the temperature is increased. A liquid is formed from a vapour by the reverse procedure. However, for many mixtures there are limited ranges of pressure and temperature near the critical point where retrograde condensation occurs. Within these ranges a liquid phase is formed when the pressure is lowered. Repressuring operations that take advantage of this situation are conducted in the oil fields. The pressure in the underground structure is not allowed to decrease beyond a certain point. This pressure maintains a single gaseous phase underground. The single phase is brought to the surface where the pressure is reduced somewhat and a liquid phase separates. The remaining gas phase is returned to the ground to maintain the high pressure there. (See PHASE EQUILIBRIA.)

Synthetic Ammonia Process.—The synthesis of ammonia is an example of a high-pressure chemical process. Pressure increases the amount of ammonia formed from hydrogen and nitrogen at equilibrium. However, the reaction takes place too slowly to be of commercial importance unless a catalyst is used. In the presence of a catalyst, increased pressure also increases the

rate of reaction. The process is then commercially successful. The catalyst is iron, but the method of preparation and the nature of the iron surface on which the reaction takes place are of great importance. A smooth iron surface or iron shavings are ineffective. Other noncatalytic agents should also be present in the iron to promote its activity. A typical catalyst, before it is made active, contains 66% Fe_2O_3 , 31% FeO , 1.0% K_2O and 1.8% Al_2O_3 . These materials must be free from impurities which would act as catalyst poisons. The mixture is fused into a solid mass by passing an electric current through it. Then it is broken up and screened, and the -3 to $+6$ mesh (per inch) fraction is used, although it must be activated before it will produce ammonia. Activation consists of reducing the iron oxides by passing the hydrogen and nitrogen synthesis gas over them according to a predetermined time schedule, with gradually increasing temperature. After the catalyst is activated it cannot be exposed to air and must be kept continuously in a reducing atmosphere. Impurities such as sulphur, phosphorus and arsenic will poison the catalyst permanently, reducing its activity, while oxygen, water vapour and carbon oxides are temporary poisons and reduce the activity only as long as they are present in the synthesis gas stream.

The synthesis reaction is carried out in a large complicated pressure vessel called a converter. The catalyst is maintained at a temperature in the range from 750° to $1,050^{\circ}\text{F}$., according to the process and the condition of the catalyst. The high temperature is confined to the inner regions of the converter; the walls which must withstand the pressure are at a much lower temperature, not over 120°F . in some cases. The synthesis gas entering the converter is relatively cool and is heated to the reaction temperature by heat exchangers within the converter. The heat generated by the reaction in the catalyst bed must be removed to prevent overheating and damage to the catalyst.

A typical converter designed for operation in the high-pressure range, at about 1,000 atm., is a thick-walled carbon steel vessel containing a basket, or cartridge, which includes both a heat-exchanger and tubes of catalyst. (See fig. 1.) The heat exchange is carried out in the same region as the catalytic reaction. The cold incoming gas enters at the bottom and moves upward through a narrow passage between the inside of the converter wall and the cartridge, keeping the wall cool. The catalyst tubes are arranged in closely spaced concentric circles and are fitted with internal baffles to aid in removing the heat of reaction. The region outside the tubes also is provided with baffles to improve the gas flow distribution and provide local high velocity and turbulence to improve the heat transfer. Synthesis gas enters the cartridge near the top, flows downward around the catalyst tubes and into a mixing chamber where it may be heated electrically if necessary. It then flows upward through the catalyst tubes. The reaction is rapid in the lower part of these tubes and slow in the upper part so the gas is cooled considerably before it leaves the catalyst. Each converter contains about 16.5 cu.ft. of catalyst and produces from 250 to 400 lb. of ammonia per hour per cubic foot of catalyst.

For use at lower pressures, in the range from 250 to 350 atm., the walls of the converter are made of medium-carbon steel and are kept cool by a portion of the cool synthesis gas entering at the top and flowing down through an annular space inside the converter wall. The main flow of synthesis gas enters at the bottom and, after mixing with that from above, flows upward around the tubes of a heat exchanger. There it receives heat from the hot gases which have just left the catalyst and are flowing down inside the tubes. The catalyst is in a continuous bed above the heat exchanger, and tubes for the partially preheated synthesis gas pass up through this bed. The reacting gas flows downward through the bed.

Such a converter contains about 144 cu.ft. of catalyst and produces about 80 lbs. of ammonia per hour per cubic foot of catalyst. (See fig. 2.)

In the high-pressure process, hydrogen for the reaction is obtained from steam and natural gas, while the nitrogen comes from the air. The synthesis gas is prepared and then carefully purified and compressed to reaction pressure. Only a part of the hydrogen-

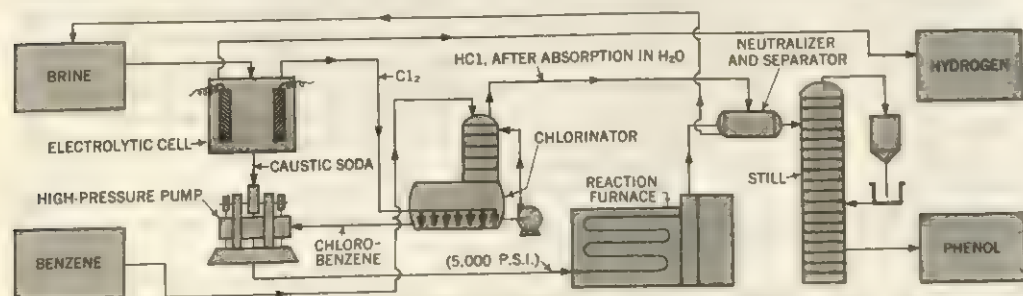

FIG. 2.—AMMONIA SYNTHESIS CONVERTER FOR OPERATION AT 280-300 ATM.
(After A. V. Slack, H. Y. Atigood and H. E. Maune)

nitrogen mixture is converted to ammonia in one pass through a converter. This ammonia is condensed and removed and the remaining gas is passed through a second converter. The unconverted gas is then mixed with make-up gas and recirculated to the first converter.

At 1,000 atm. the conversion per pass through the synthesis reactor is considerably greater than at lower pressures. Approximately one-seventh as much catalyst and converter volume is required to produce the same quantity of ammonia, and about one-fifth as much gas must be pumped and piped on the basis of actual volume at synthesis conditions. Economic factors at each plant location dictate operating conditions.

Other High-Pressure Processes.—The process for synthesizing methanol is in general similar to that for ammonia. The catalyst consists of aluminum oxides, copper and zinc oxide containing chromium. Typical operating conditions are 200 atm. and 750° F. With a similar catalyst, which is made alkaline by the addition of potassium carbonate or chromate, and at temperatures from 750° to 1,000° F. and pressures from 200 to 1,000 atm., higher alcohols are formed.

Fig. 3 shows the manufacture of phenol from chlorobenzene; the raw materials are sodium chloride brine and benzene. The brine is fed to an electrolytic cell and the chlorine produced in this cell is used to chlorinate the benzene. An 18% sodium hydroxide solution derived from the cell is mixed with the chlorobenzene; this mixture is raised to a pressure of 5,000 p.s.i. and passed through a continuous-pipe pressure reactor constructed of 2 in. diameter pipe in long coils in a furnace. This mixture is heated to 360° C.; the pressure maintains a single phase and increases the mutual solubility of the ingredients; the hydrolysis reaction takes place, and sodium phenolate is formed. The sodium phenolate is neutralized with hydrochloric acid, regenerating a salt brine, and

FIG. 3.—FLOW SHEET OF A COMMERCIAL PROCESS FOR MANUFACTURING PHENOL FROM CHLOROBENZENE AT 5,000 LB. PER SQUARE INCH

the phenol is distilled from the mixture.

The successful synthesis of diamonds was announced by the General Electric company in 1955. Diamonds are a crystalline form of pure carbon. They are formed when carbon is subjected to extremely high pressure and high temperature with a catalyst for sufficient time. This and other solid state reactions require that pressures of 50,000 to 100,000 atm. and temperatures of 1,500° to 2,500° C. be maintained for hours at a time.

Equipment.—Chemical reactions are carried out in steel or alloy vessels at high pressure. In continuous processes high-pressure tubing, fittings and compressors are required. Closures and fittings are frequently of a special design so that the internal pressure assists in making a tight seal. A large number of designs are available for high-pressure equipment to be used under a variety of special conditions.

A variety of alloys are often used in a single piece of equipment. The wall of an ammonia converter, for example, may be selected to resist the high internal pressure at low temperature, while the liner material may be chosen to resist the corrosive action of the contents. The catalyst tubes may be selected to resist the combined action of high temperature, hydrogen and nitrogen, but not to confine the high pressure.

At high pressure both hydrogen and nitrogen attack steel and certain alloys. Hydrogen apparently is adsorbed on the surface of steel. It ionizes and the protons pass through the openings of the metal lattice. They slowly react with carbon in the steel to form methane, which accumulates at the grain boundaries. The internal pressure built up by the methane forces the grains apart resulting in such permanent damage as intercrystalline cracking, fissuring, blistering and decarburization.

The introduction of strong carbide-forming elements such as titanium and vanadium has helped materially to reduce the effects of hydrogen. Austenitic stainless steels and beryllium-copper are examples of alloys which do not seem to be subject to hydrogen attack.

Newitt, *The Design of High Pressure Plant and Properties of Fluids at High Pressure* (1940); E. W. Comings, *High Pressure Technology* (1956). (E. W. C.)

PRESSURE GAUGE can be defined in general terms as an instrument or instrument system for measuring pressures of gases and liquids. Types of pressure gauges include vacuum gauges (see VACUUM: *Vacuum Gauges*), barometers, manometers and dead weight piston gauges, as well as the more common Bourdon tube gauges. Also included is equipment for measuring rapidly changing pressures such as engine indicators, or piezoelectric crystal pickups or other pressure transducers, arranged to indicate or record pressure variations by use of an oscillograph, or other means.

Pressure gauges may indicate or record pressure at the location of the pressure-sensing element, or pressure information may be transmitted to a remote point for observation.

Pressure gauges are available for accurate measurement of the minute pressures existing in vacuum systems, to pressures of several hundred thousand pounds per square inch necessary in research and some industrial processes. Various types of instruments are specifically designed for making measurements of pressures over a wide range of pressure rate of change, from static or slowly changing pressures, such as atmospheric pressure, to the very rapidly changing pressure transients of explosions. Pressure gauges may be designed for measurement of absolute pressure or gauge pressure or differential pressure as explained below. Pressure measurement is of primary importance in the chemical process industry, in power plants, aeronautics and meteorology.
